Suggestions for local impact modelling
Background and purpose
This study is divided into two major parts: an inventory of the available information sources for local nature system data in Sweden and an overview of the needs of nature system data for local adaptation of impact assessment tools and methods.

The study is a result from the CPM project IMPRESS (IMPlentation of integRated Environmental information SystemS). It is a pre-study for the activity “Development of strategies for continuous data acquisition” in the “General methodology development” subproject.

The intended application of the data is for local adaptation of impact assessment models which will be made in the “Environmental management at site and group level” subproject of IMPRESS. The local impact assessment models can be used for life cycle assessment (LCA), in environmental management systems (EMS) or for other suitable purposes.

The today available impact assessment methods have only modelled the effects on the macro scale, i.e. for the whole geographical area that the method is valid for. The Swedish method EPS 2000 has a global range and the models are thus on a global scale the Danish method EDIP has a European range and the models are on a European scale etc. Information about the environmental impacts on a global scale is seldom enough for an industrial company, as local environmental impacts from the company’s activities are what most concerns stakeholders such as local authorities, neighbors and NGOs.

Nature system data
With nature system data is meant data about the nature and changes in the nature conditions, in opposition to technical and social system data that lies outside the scope of this study. An example of a nature system data source is the Swedish Species Information Centre¹ (ArtDatabanken) which contains lists of endangered species, their habitats and the main cause to why they are threatened.

Technical system data is data about products, services or production processes for which the source is generally the company itself. An example of a technical system data source (outside the scope of this study) is the Swedish pollutant release and transfer register² (Kemikalieutsläppsregistret).

Social system data is data about prioritizations between different environmental problems. This data is the subjective observations and valuations of people. An example of a social system data source (outside the scope of this study) is the official statistics

¹ http://www.artdata.slu.se/
² http://www.naturvardsverket.se/kur/
provided by the National Board of Health and Welfare (Socialstyrelsen) about health and disease, health care and medical services and care of individuals and families.

The figure below describes the relations between the three types of data that is needed to make an impact assessment of a human activity.

![Figure 1](image-url)

*Figure 1* is a conceptual model that describes the three different origins of environmental information. The Technical system represents information that describes industrial processes and systems of such processes, i.e., data from engineering disciplines. The Nature system represents information that describes nature or other human living spaces, i.e., data from ecological disciplines. The Social system represents information about the non-physical aspects of human beings, i.e., data from humanities disciplines.

---

3 [http://www.socialstyrelsen.se/](http://www.socialstyrelsen.se/)
Inventory of nature system data sources

As the intended application of the data is for future local adaptation of impact assessment models, the scope for the inventory is continuous data sources. With continuous data sources is meant that the data collection is continuous. The data sources must also be publicly available to be considered interesting as a source for impact assessment. Data can either be downloaded directly from a web site or deliveries are made on demand, and sometimes an administrative fee must be paid. The geographical scope of the inventory is Sweden, and as example for the regional and municipal data sources is chosen the Gothenburg region.

The inventory shall by no means be seen as a complete list of the sources for nature system data in Sweden but the results of a three week project in Spring 2005. The data quality of the different sources has not been assessed, more than that the availability of the data is sufficient. An aggregated list of all inventoried Swedish information sources and references to where to find them is provided in Swedish in Appendix I.

Swedish Environmental Monitoring Programme
(Miljöövervakningen)

National monitoring programme

The national monitoring programme is a system for continuous documentation of the state of and change in the environment, divided in ten different program areas:

- Air
  - Air pollutants and precipitation
- Sea and coastal areas
  - Stock size, brood size and hazardous substances in marine fauna
- Freshwater
  - Physical, chemical and biological parameters in freshwater
- Mountains
  - Changes in vegetation and species, hazardous substances in fauna
- Forests
  - Soil, soil chemistry and changes in vegetation and species
- Agriculture
  - Nutrients and pesticides in surface water and groundwater
- Health related environmental monitoring
  - Exposure from air and food, allergic responses
- Landscape
  - Landscape structure, land use and biodiversity
- Wetlands
  - Wetland conditions and biodiversity
- Toxic substances coordination
  - Screening and specimen banking

The program areas are in their turn divided in subprograms, see Appendix II (only in Swedish). The assignment of funds for the national monitoring programme is made by
the Swedish Environmental Objectives Council at the Swedish EPA, and was 132 million SEK in 2005\(^4\). The execution of the surveillance is commissioned to other parties, e.g. universities, consulting agencies, research institutes or other authorities. Eight of the parties also function as “data hosts”:

- Swedish Meteorological and Hydrological Institute (SMHI)
- IVL Swedish Environmental Research Institute
- The Geological Survey of Sweden (SGU)
- The Swedish University of Agricultural Sciences (SLU)
- The National Board of Fisheries
- Department of Systems Ecology, Stockholm University (SU)
- The Institute of Environmental Medicine, Karolinska Institutet (IMM)
- Swedish Institute for Infectious Disease Control (SMI)

Figure 2 below shows a graphical description of the national monitoring programme.

![Graphical description of the national monitoring programme](image)

**Figure 2.** The national monitoring programme and the data hosts. The program areas that have no arrows connecting them to a data host store the data at the local County Administrations.

The data hosts are responsible for collecting, storing, quality reviewing, aggregating and administering the data. The Swedish EPA has developed guidelines for planning and design of monitoring activities\(^5\) and also quality directives for the data management\(^6\).

---

They are obliged to deliver data on request in exchange for an administrative fee for non-commercial interests, and for payment for commercial interests. See Appendix III for more specific information about format and links.

Some of the data hosts (SMHI and SGU) keep their data centrally available in the database MiljöDataSök, which is publicly available on the internet\(^7\). Here data from the national monitoring programme can be found with different search criteria, e.g. data host, chemical or physical variables and drainage areas. Other data hosts plan to make it available there in a short time (IVL, SLU). The data from the national monitoring programme is also used for international reporting, to the EEA and other authorities, with supplementing additions from the regional monitoring programme.

More information about the national monitoring programme can be found at the Swedish EPA website\(^8\).

### Regional monitoring programme

The Swedish EPA is also responsible for coordination of the regional monitoring programme, which is independently performed by the County Administrations\(^9\) (Länsstyrelser). The County Administrations coordinate the different activities in the county performed by Regional Forestry Boards, Air and Water Conservation Societies, municipalities and other local authorities, industries and NGOs.

\(^7\) [http://www.naturvardsverket.se/miljodatasok/start.jsp](http://www.naturvardsverket.se/miljodatasok/start.jsp)

\(^9\) [http://www.lst.se](http://www.lst.se)
monitoring programme is to provide information about the state of the environment to the citizens of the Counties. The national data hosts do not yet provide reporting and presentation of the data on regional basis and the Counties do therefore not see enough benefits for them to make it worth the cost of delivering their data. EPA encourage the Counties to deliver as much data as possible to the national data hosts, but all data is still not transferred due to lack of money, time and mismatching data formats and nomenclatures. This means that data produced within the regional monitoring programme is spread out on the respective Counties and the national data hosts. There is currently no reference register of all the data kept in the different databases.

The County Administration of Södermanlands län is responsible for the database DMN (Databas för Miljö- och Naturvård) in which the data from the regional monitoring programme was previously supposed to be gathered. The thought of keeping one big database with all data from the Counties has now been abandoned by the EPA, but is thus kept on in Södermanlands län.

The assignment of funds for the regional monitoring programme is made by the Swedish Environmental Objectives Council at the Swedish EPA, and was 23 million SEK in 2005. More information about the national monitoring programme can be found at the Swedish EPA website.

Swedish Meteorological and Hydrological Institute (SMHI)

SMHI, Swedish Meteorological and Hydrological Institute, is the national data host for atmospheric air and marine data. In addition to administering the data from various measurement stations, SMHI runs the subprogram Sverigemodellen which is a model for calculation of dispersion and downfall of air pollutants. The model divides Sweden in sections and calculates values also where there are no measurement stations with the MATCH (Mesoscale Atmospheric Transport and CHemistry) model. For air pollutants there is thus measured or modelled data covering the whole country. The calculations are based on data from Nordic EMEP stations and the Swedish Luft och Nederbördskemiska Stationsnätet.

SMHI has also developed a web based tool for assessment of air quality in areas close to roads (SIMAIR) together with the Swedish Road Administration, the Swedish EPA, the Swedish Energy Agency, University of Stockholm and IVL Svenska Miljöinstitutet AB.

16 http://www.smhi.se/sgn0106/if/meteorologi/match.htm
18 http://simair.smhi.se/
The Swedish University of Agricultural Sciences (SLU)

SLU, the Swedish University of Agricultural Sciences\(^{19}\) is the national data host for agricultural, wetland and inland water data. In addition, SLU has been commissioned to run the work with the Swedish Species Information Centre (ArtDatabanken) together with the Swedish EPA. The Swedish Species Information Centre’s main tasks are to collect, evaluate and store the most important information about threatened and rare plant and animal species. A basic part of this work is to assess the types and degrees of threat, and to prepare the national Red List and Red Data Books. In the Red Lists every species is described with Red List Category and their occurrence in different administrative provinces.

IVL Swedish Environmental Research Institute

IVL Swedish Environmental Research Institute\(^{20}\) is the national data host for air pollution and toxic substances in biota. The data is presented for each measurement station in the form of maps and reports. IVL is also commissioned by the Swedish government to run a competence centre for effects of discharges of oil and chemicals. An atlas is being constructed that informs about particularly sensitive areas.

The Swedish National Atlas (SNA)

The Swedish National Atlas\(^{21}\) is the official thematic map office in Sweden, operated by Lantmäteriverket\(^{22}\). Six Swedish authorities are participating in the work; the Swedish EPA, Statistics Sweden (SCB), Riksantikvarieämbetet, the National Board of Forestry, the Geological Survey of Sweden (SGU) och Lantmäteriverket. SNA provides books, the GIS based PC-Atlas, the WebAtlas and a Swedish Gazetteer\(^{23}\). The themes are Work and leisure, Population, Geology, Climate, lakes and rivers, Environment etc. Under the theme Environment can be found information about acidified lakes, distribution of rare species, occurrence of heavy metals in animals etc., presented graphically with maps.

The Swedish Radiation Protection Authority, SSI

The Swedish Radiation Protection Authority\(^{24}\) has the responsibility to follow up the environmental objective “A Safe Radiation Environment”. A database with radiation environment data is currently being built up. Information about radiation doses, content of cesium-137 in different species etc. can be found.

\(^{22}\) [http://www.lantmateriet.se/](http://www.lantmateriet.se/), Lantmäteriet provides the Swedish society - the public and private sectors, the general public and a wide range of other users - with geographic information in the form of maps, aerial photography and satellite imagery.
\(^{23}\) Ortregistret in Swedish.
\(^{24}\) [http://www.ssi.se/](http://www.ssi.se/)
**The County Administration of Västra Götaland**

The County Administrations\(^{25}\) are responsible for coordination of the regional monitoring programme in the county. The information from the regional environmental monitoring is intended to be used to provide information to the County citizens and also for environmental impact assessments\(^{26}\). The environmental impact assessments are performed when companies and other organizations plan to start or enlarge activities or measures that may have detrimental impact on the environment and require a permit\(^{27}\).

In the County of Västra Götaland, data is stored at the County Administration and/or at the national data hosts, in Excel or Access format. The data is public and delivered for free on demand. In addition, there is data about marine and fresh water conditions stored at the water conservation societies of the Bohus Coast, Götä Älv etc.\(^ {28}\) A list with all the water conservation societies in the County of Västra Götaland is found in Appendix IV.

Several organizations participate in the data collection for the regional environmental monitoring, and data can also be retrieved directly from them. For example there is a Gothenburg Region’s Air Quality Programme\(^ {29}\) which is based on work co-operation between the local councils and companies in the region, also including the counties of Västra Götaland and Halland, Chalmers University of Technology, and the University of Gothenburg.

**Göteborgs stad**

Miljöförvaltningen\(^ {30}\) is the municipal body with responsibility for the follow-up of the environmental goals of the city of Gothenburg and for informing the citizens of the municipal environmental condition in Göteborg, and performs local inventorying and monitoring of air, water and ground. Some examples are monitoring of beaches and inventorying of polluted land areas. Both measured and calculated data is used. The data is stored at Miljöförvaltningen and published in reports.

Miljöförvaltningen runs the biodiversity database ADA\(^ {31}\) (Göteborgs artdataarkiv) which contains information about the biodiversity and red listed species in the municipality of Gothenburg. The air quality measurements are performed cooperatively with the Gothenburg Region’s Air Quality Programme (see above). Miljöförvaltningen offers an on-line service called Luftnet\(^ {32}\) with reports on weather and air quality in Gothenburg.

Non-continuous data sources

Non-continuous data sources have the disadvantage that they might possibly not be updated in the future. It might also not be possible to find data back in time to compare the new figures with. However, non-continuous data sources like scientific studies, studies made by non-governmental organizations, companies, etc. can provide useful nature system information.

SWECLIM

SWECLIM\textsuperscript{33} is an example of a non-continuous data source. The Swedish Regional Climate Modelling Programme (SWECLIM) was part of an international and Nordic cooperation in the field of climate modelling. A set of regional climate modelling tools were established and regional climate scenario examples were provided for Swedish users. The aim was to increase the knowledge and awareness of long-term climate changes.

European data sources

There is also nature system data that is compiled at a European level. Most of it is however aggregated national data from the European countries.

European Environmental Agency (EEA)

The European Environmental Agency (EEA)\textsuperscript{34} is commissioned to provide decision makers in the European Union with the necessary information to design, implement, and follow up an efficient environmental policy. EEA is also commissioned the task of maintaining and developing the European network for environmental information and environmental monitoring. There are several useful products provided by EEA, some of which are presented below.

Europe’s Environment

The third pan-European state of the environment report produced by the EEA\textsuperscript{35}. It was prepared for the 'Environment for Europe' Ministerial Conference being held under the auspices of the UN Economic Commission for Europe in Kiev, Ukraine on 21-23 May 2003. In contrast to previous reports issued in 1995 (the Dobris assessment) and 1998, it covers for the first time the entire Russian Federation and the 11 other Eastern European, Caucasus, and Central Asian (EECCA) states.

EUNIS

The EEA provides access to the database EUNIS (EUropean Nature Information System)\textsuperscript{36}. EUNIS consists of a central unit integrating data models on species, habitats and sites; several secondary databases which are managed by different partners; and an

\textsuperscript{33} \url{http://www.smhi.se/sweclim/}
\textsuperscript{34} \url{http://www.eea.eu.int/}
\textsuperscript{35} \url{http://reports.eea.eu.int/environmental_assessment_report_2003_10/en}
\textsuperscript{36} \url{http://eunis.eea.eu.int/index.jsp}
increasing number of satellite databases. Data include for example those provided by Member States when describing the proposed NATURA 2000 sites. Provided by the European Topic Centre on Biological Diversity (ETC/NPB)\textsuperscript{37}.

**Waterbase**

Waterbase is the generic name given to the EEA's databases on the status and quality of Europe's rivers, lakes, groundwater bodies and transitional, coastal and marine waters, and on the quantity of Europe's water resources. Waterbase contains data collected from EEA member countries through the Eurowaternet\textsuperscript{38} (EWN) process. EWN selects validated monitoring data from national databases and adds information on the physical characteristics of the water bodies being monitored and on the pressures potentially affecting water quality. Provided by the European Topic Centre on Water (ETC/WTR)\textsuperscript{39}.

**Databases on Air Quality, Air Emissions & Climate Change in Europe**

Databases with data on the European air are provided by the European Topic Centre on Air and Climate Change (ETC/ACC)\textsuperscript{40}.

\textsuperscript{37} [http://biodiversity.eionet.eu.int/](http://biodiversity.eionet.eu.int/)
\textsuperscript{39} [http://water.eionet.eu.int/](http://water.eionet.eu.int/)
\textsuperscript{40} The ETC/ACC has been established in 2001 by the EEA. The ETC/ACC is a consortium of 14 European institutions with RIVM-MNP as its lead organization. Viewed at [http://air-climate.eionet.eu.int/](http://air-climate.eionet.eu.int/)
Data need in methods and tools

The aim with the study was to adapt a global impact assessment model for local impact assessment and state which nature system data is needed for the local conditions.

The general form for an impact model is a mathematic expression for the impact on an indicator as the consequence of a certain load. The mathematical expression is built up of nature and/or substance properties, as illustrated in the figure below.

![Figure 4. A general impact model. The characterization factor is a mathematical expression for the impact on an indicator as the consequence of a certain load. The characterization factor is a function of nature and/or substance properties.](image)

To be able to identify exactly which nature system data is needed, a case study was made where the eutrophication impact modelling method of EPS 2000 was adapted to local impact assessment. Three substances were chosen, N-tot (total emission of nitrogen to water), P-tot (total emission of phosphorous to water) and COD (chemical oxygen demand).

**Eutrophication**

An increased input of phosphorus and nitrogen to water bodies with low oxygen concentrations leads to eutrophication, which has negative effects such as increased turbidity, accelerated oxygen depletion due to the decay of organic matter, and changes in the diversity and composition of flora and fauna. In fresh water, it is usually the supply of phosphorus that regulates the production of algae and other plants, while in marine water it is the supply of nitrogen. COD (chemical oxygen demand) refers to a group of substances that also contributes to the damage by consuming oxygen in water bodies where the oxygen concentration is already low. In water bodies without risk for oxygen deficiencies the nutrients can have positive effects such as increased fish production.

Oxygen depletion is widely used as an indicator for eutrophication. While oxygen levels above 4.5 ml/l are considered to cause no problems for macroscopic animals, levels below this cause increasing stress to most organisms. Another indicator of eutrophication is the concentrations of nutrients in the water body. A lake is considered hypertropic if the phosphorous content is more than 100 µg P/l. A third indicator of eutrophication is the primary production (the synthesis of organic matter (C) by plants) that is dependent on phosphorous emissions, turbidity and depth. A lake is considered eutrophic if the primary production exceeds 75-250 g C/m² and year.

**Eutrophication environmental aspects**

To be able to take care to the different nature conditions described in the previous section a distribution model for water bodies can be created that will describe which areas that are exposed to the emissions. Distribution models are in general very expensive and another solution is to divide the emissions of N-tot, P-tot and COD into different environmental aspects after the nature criteria:

- **N-tot**
  - Emission of N-tot to fresh water with high oxygen concentration
  - Emission of N-tot to fresh water with low oxygen concentration
  - Emission of N-tot to marine water with high oxygen concentration
  - Emission of N-tot to marine water with low oxygen concentration

- **P-tot**
  - Emission of P-tot to fresh water with high oxygen concentration
  - Emission of P-tot to fresh water with low oxygen concentration
  - Emission of P-tot to marine water with high oxygen concentration
  - Emission of P-tot to marine water with low oxygen concentration

- **COD**
  - Emission of COD to fresh water with high oxygen concentration
  - Emission of COD to fresh water with low oxygen concentration
  - Emission of COD to marine water with high oxygen concentration
  - Emission of COD to marine water with low oxygen concentration

This way, the responsibility for estimating (or measure) the conditions of the local environment is given to the person collecting the emission data for the environmental aspects, which is supposed to be a person with good knowledge of the geographical location. Generally, the marine water bodies south of the Åland Sea are considered to be N limited, and the water bodies north of the Åland Sea P limited. Fresh water bodies such as lakes and water courses are P limited. Suggested local characterization factors for these environmental aspects can be found in Appendix VI.

**EPS 2000 – Environmental Priority Strategies in product development**

The impact assessment method EPS 2000\(^{45}\) was developed within CPM (Centre for the environmental assessment of Products and Material systems). EPS uses three different ways to model impact; *empiric*, where the top-down perspective is applied, *mechanistic*, where the bottom-up perspective is applied, and *equivalency* modelling where the impact from one substance is estimated based on comparison with the impact from a similar substance.

The environmental impact due to eutrophication is assigned to the following impact categories:

- **Biodiversity**  
  Category indicator: NEX  
  NEX is an abbreviation of “Normalised EXtinction of species”. The extinction rate of species in the world is not known. The indicator value for normal extinction rate of species is set to 1 NEX (NEX is also the indicator unit). This means that an activity that hypothetically account for 50% of the world’s extinction of species will get an indicator value of 0.5 NEX.

- **Ecosystem production capacity**  
  Category indicator: Fish and meat  
  The production rate of fish is an indicator of eutrophication. The indicator unit is kg.

- **Recreational and cultural values**  
  Category indicator: *none defined*

**Choice of local category indicators**

The choice of category indicators for the local impact modelling was made by Professor Bengt Steen at the Department of Environmental Systems Analysis at Chalmers University of Technology together with Johan Tivander and Sandra Häggström, both at Industrial Environmental Informatics at Chalmers University of Technology.

**Indicators for biodiversity**

The extinction rate of species due to eutrophication is not known. In EPS it has been estimated with the fraction of red listed species that are assumed by science expertise to be threatened by eutrophication. In Scandinavia for example, 10% of the red listed species are assumed to be threatened by eutrophication\(^{46}\). The category indicator value for eutrophating substances’ impact on NEX is therefore 0.1 NEX. This empirical way of modelling does not suit adaptation to too small areas.

\(^{46}\) ArtDatabanken, “Rödlistade arter i Sverige”, [http://www.artdata.slu.se/](http://www.artdata.slu.se/)
Indicators for ecosystem production capacity
The effect on the production rate of fish due to addition of eutrophicating substances is described by the figure below.

![Fish production graph](image)

**Figure 5.** Fish production as a function of concentration of nutrients.

The effect of adding eutrophicating substances or nutrients to water is dependent on the oxygen concentration in the water. If the oxygen concentration is high, the nutrients will lead to an increase of fish production, but when the water is eutrophicated, the oxygen concentration will be so low that there is a reduction in fish production and also a risk that species can be extinct (i.e. impact on the NEX indicator). The local impact model will need to take care to the oxygen concentration of the drainage areas to which the emission of eutrophication substances is made. An introduction of conditions for the models will lead to that the model for increased growth can be used when the oxygen concentration is above a certain value and the model for decreased growth can be used when the oxygen concentration is below that value.

Indicators for recreational and cultural values
A discussion was held about other indicators of environmental impact that might be suitable for local impact modelling. The subjectivity of the selection of safe guard objects and/or environmental issues was however considered too high. Cultural and recreational values, the EPS impact category, can e.g. also be represented by the production rate of fish and additions of new category indicator were decided to be left outside the scope.
EPS characterization factors for eutrophication
Below are the specific expressions of the characterization factors (CF) in EPS 2000.

**N-tot impact on NEX**
Modelled with empirical method
\[ CF = \frac{A \times B}{C} \]
A = relative size of n-polluted (ocean) water area  
B = ratio of extinction of species caused by eutrophication \([\text{NEX}]\)  
C = global emission of nitrogen to water \([\text{kg}]\)

**N-tot impact on fish and meat**
Modelled with mechanistic method
\[ CF = \frac{-A \times B \times (C-D)}{(D \times E)} \]
A = share of nitrogen emissions ending up in areas where the growth rate is limited by nitrogen  
B = average fish production in Swedish waters \([\text{kg/hectare*year}]\)  
C = weight of bottom fauna 1984 \([\text{g/m}^2]\)  
D = weight of bottom fauna 1912 \([\text{g/m}^2]\)  
E = anthropogenic added nitrogen \([\text{kg/hectare}]\)

**COD impact on NEX (determined by an equivalency method using N-tot as a reference)**
Modelled with equivalency method with N-tot as reference
\[ CF = A \times B \times C \]
A = part of COD mineralized  
B = relative rate of consumed oxygen for COD/N-tot  
C = CF for N-tot

**P-tot impact on NEX**
Modelled with empirical method
\[ CF = \frac{A \times B}{C} \]
A = relative size of P-polluted (lake) area  
B = ratio of extinction of species caused by eutrophication \([\text{NEX}]\)  
C = global emission of phosphorous to water \([\text{kg}]\)
Adaptations

Phosphorous contribution to increased fish production

The impact on fish production from phosphorous was not modelled in EPS 2000 due to the fact that it has both positive and negative impacts depending on the oxygen level in the water\(^\text{47}\). By introduction of conditions in the model, phosphorous impact has been modelled here. When emitted to n-limited water bodies, phosphorous is assumed to have zero impact, and when emitted to p-limited water bodies it is assumed to cause all the eutrophication effects. If the oxygen concentration is below a certain value, then the “eutrophication model” is valid. If the oxygen concentration is above that value, then the “nutrient model” is used. The P-tot impact on fish and meat can be modelled with an equivalency method with N-tot as reference.

According to Matts-Ola Samuelsson\(^\text{48}\), 1 mole of P equals 16 moles of N in eutrophicating effect and translated to kilograms 1 kg of P equals 7 kg of N. This figure corresponds to the content of nutrients in fish fodder\(^\text{49}\) where there is 8 times as much P to N. The equivalence factor is thus set to 7. The uncertainty in the equivalence factor is assumed to be the same as for the equivalence factors in EPS 2000, i.e. described by a log-normal distribution with a standard deviation corresponding to a factor of 5.

Models for decrease of fish production due to eutrophication

The EPS model for increase of fish production due to anthropogenic emissions of nutrients is based on an investigation of the fish production in Skälderviken. The uncertainty factor when using the results for other parts of the world is assumed to be in the order of factor \(^\text{450}\). An investigation of Kalmarsund made by the National Board of Fisheries shows an example of reduced fish recruitment due to emissions of nutrients\(^\text{51}\). Using this data is here assumed to have the similar uncertainty as the Skälderviken data when applying it to other parts of the world.

According to Fiskeriverket, the catch of perch was in the early 90’s about 100 ton per year in the Kalmar coastal water body\(^\text{52}\). In 1995 the total emissions of nutrients to this area was 5000 ton of nitrogen/year. The catch of perch decreased in the period 1990 to

\(^{51}\) Johansson (2000):”Åtgärdsanalys av övergödningsproblemet i Kalmar läns kustvatten”, Meddelandeserien nr 2001:18, ISSN 0348-8748
1997 with 12 percent per year, or 12 ton per year\textsuperscript{53}. An empirical model can thus be made for the decrease of fish production due to nitrogen emissions, where the characterization factor $\text{CF} = \text{decrease in fish recruitment [kg fish/year]} / \text{emission of nitrogen [kg/year]}$.

The decrease of fish production due to emissions of COD and phosphorous can be modelled with an equivalence method just as with the EPS characterization factor for COD and phosphorous impact on NEX.

**Nature data needed for local impact assessment**

The list below is a guide to some of the nature properties (in the models for eutrophication above) that are dependent on the local conditions, and where it is possible to find information. It is not intended as a complete list and the first part of this report, the inventory of nature data sources contains more references to possible data sources.

**Oxygen concentration in fresh water bodies**

Data about oxygen concentration in the reference water courses (50), river mouths (50) and lakes (95) can be found and downloaded for free at the website of the Environmental Assessment department\textsuperscript{54} at the Swedish University of Agricultural Sciences. The location, year, month, day, depth [m], oxygen concentration [mg/l] is specified in the data set. Maps of the reference water courses, river mouths and lakes are found in Appendix V. If the fresh water area in a specific study is not a reference area, it has to be estimated with one.

High phosphorous content is another indicator of that the water area is eutrophicated if no reliable data about oxygen concentration can be found. For lakes, a list of the lakes that had a concentration of phosphorous of more than 100 µg/litre (yearly average) and thus regarded as hypertrophic was compiled in 1990 from a questionnaire to the County Administration\textsuperscript{55}.

**Oxygen concentrations in marine water bodies**

National monitoring programme data can be downloaded for free from the SHARK database (Svensk HavsARKiv)\textsuperscript{56}. Regional data about marine concentrations of oxygen can be found and ordered at the Swedish Meteorological and Hydrological Institute for an administrative fee\textsuperscript{57}.

Anthropogenic emissions of nutrients
The anthropogenic emissions of phosphorous and nitrogen in Sweden can e.g. be found at
the Swedish Meteorological and Hydrological Institute 58 or the Swedish University of
Agricultural Sciences 59. Emissions of phosphorous and nitrogen in Europe can be found
in the European Pollutant Emission Register (EPER) 60, which is a European-wide register
of industrial (which includes e.g. agriculture) emissions into air and water (Norway and
Hungary are also included).

Normal extinction rate of species (NEX)
The extinction rate of species due to eutrophication is not known. In EPS it has been
estimated with the fraction of red listed species that are assumed by science expertise to
be threatened by eutrophication. In Scandinavia, 10% of the red listed species are
assumed to be threatened by eutrophication 61. On a global scale it is supposed to be 1%
as warmer regions are less sensitive to excess nitrogen 62. This empirical way of
modelling does not suit adaptation to too small areas, and using the fraction of red listed
species to smaller areas than Scandinavia is therefore not recommended.

Suggestions for local impact modelling
The following environmental aspects are classified to the impact category NEX:

• Emission of N-tot to marine water with low oxygen concentration
• Emission of P-tot to fresh water with low oxygen concentration
• Emission of COD to fresh water with low oxygen concentration
• Emission of COD to marine water with low oxygen concentration

The following environmental aspects are classified to the impact category increased fish production:

• Emission of N-tot to marine water with high oxygen concentration
• Emission of P-tot to fresh water with high oxygen concentration

The following environmental aspects are classified to the impact category decreased fish production:

• Emission of N-tot to marine water with low oxygen concentration
• Emission of P-tot to fresh water with low oxygen concentration
• Emission of COD to fresh water with low oxygen concentration
• Emission of COD to marine water with low oxygen concentration

If other sources for the data are not specified, the data is taken from the EPS report\textsuperscript{63}, pages 262-266.

Models for impact on NEX
The geographical scope for this model is Scandinavia.

N-tot impact on NEX
Modelled with empirical method
\[ CF = \frac{A \times B}{C} = 0.9 \times 0.1 \frac{NEX}{8.6 \times 10^6 \text{ kg}} = 1.05 \times 10^{-8} \frac{NEX}{\text{kg}} \]

A = relative size of n-polluted (ocean) water area
B = ratio of extinction of species caused by eutrophication [NEX] = 0.1 NEX (1990?)
C = Scandinavic emission of nitrogen to water [kg] = 8626 ton (2001)\textsuperscript{64}

P-tot impact on NEX
Modelled with empirical method
\[ CF = \frac{A \times B}{C} = 0.1 \times 0.1 \frac{NEX}{0.9 \times 10^6 \text{ kg}} = 1.1 \times 10^{-8} \frac{NEX}{\text{kg}} \]

\textsuperscript{64} EPER, \url{http://www.eper.cec.eu.int/eper/}
A = relative size of p-polluted (lake) water area
B = ratio of extinction of species caused by eutrophication [NEX] = 0.1 NEX (1990?)
C = Scandinavian emission of phosphorous to water [kg] = 899 ton (2001)

**COD impact on NEX**
Modelled with equivalency method with N-tot as reference
\[ CF = A \times B \times C = 0.5 \times 0.102 \times 1.05 \times 10^{-8} \text{ NEX/kg} = 5.36 \times 10^{-10} \text{ NEX/kg} \]

A = part of COD mineralized = 0.5
B = relative rate of consumed oxygen for COD/N-tot = 0.102
C = CF for N-tot = 1.05 \times 10^{-8} \text{ NEX/kg} (see above)

**Models for increase of fish production**
The geographical scope for the nitrogen model is Skälderviken, but it is assumed that the figures can be applied also at other locations where no eutrophication exists. The use of the results in other parts of the world introduces an uncertainty, which is assumed to be in the order of a factor of 4.

**N-tot impact on fish increase**
Modelled with empirical method
\[ CF = -A/B = -25/56.1 = -0.446 \text{ kg fish/kg N-tot} \]
A = increased fish production = 25 kg/hectare*year
B = anthropogenic added nitrogen = 56.1 kg/hectare

**P-tot impact on fish increase**
Modelled with equivalency method with N-tot as reference
\[ CF = -A \times B = -0.446 \times 7 = -3.122 \text{ kg fish/kg P-tot} \]
A = CF for N-tot = 0.446 kg fish/kg N-tot (see above)
B = relative rate of nutrient need kg N-tot/kg P-tot = 7

**Models for decrease of fish production**
The geographical scope for the nitrogen model is Kalmarsund, but it is assumed that the figures can be applied also at other locations where eutrophication exists. The uncertainty is assumed to be the same as for increased fish production (see above).

---

65 EPER, [http://www.eper.cec.eu.int/eper/](http://www.eper.cec.eu.int/eper/)
67 According to Matts-Ola Samuelsson [Samuelsson (1993): “Life cycle assessments and eutrophication – a concept for calculation of the potential effects of nitrogen and phosphorous”; IVL Report B 1119, Stockholm], 1 mole of P equals 16 moles of N in eutrophicating effect and translated to kilograms 1 kg of P equals 7 kg of N. This figure corresponds to the content of nutrients in fish fodder where there are 8 times as much P to N [Jonsson, Alanärä (2000): “Svensk fiskodlings närsaltsbelastning – faktiska nivåer och framtida utveckling”, Swedish University of Agricultural Sciences, Umeå]. The reliability of the figures is however not guaranteed.
N-tot impact on fish decrease
Modelled with empirical method
\[ CF = \frac{A}{B} = \frac{12}{5} = 0.0024 \text{ kg fish/ kg N-tot} \]

A = decreased fish production = 12 ton/year
B = anthropogenic added nitrogen = 5 000 ton N-tot/year

P-tot impact on fish decrease
Modelled with equivalency method with N-tot as reference
\[ CF = A \times B = 0.0024 \times 7 = 0.0168 \text{ kg fish/kg P-tot} \]

A = CF for N-tot = 0.0024 kg fish/ kg N-tot (see above)
B = relative rate of nutrient need kg N-tot/ kg P-tot = 7

COD impact on fish decrease
Modelled with equivalency method with N-tot as reference
\[ CF = A \times B = 0.0024 \times 0.102 = 0.00024 \text{ kg fish/kg COD} \]

A = CF for N-tot = 0.0024 kg fish/ kg N-tot (see above)
B = relative rate of consumed oxygen for COD/N-tot = 0.102

---

69 According to Matts-Ola Samuelsson [Samuelsson (1993): “Life cycle assessments and eutrophication – a concept for calculation of the potential effects of nitrogen and phosphorous”; IVL Report B 1119, Stockholm], 1 mole of P equals 16 moles of N in eutrophating effect and translated to kilograms 1 kg of P equals 7 kg of N. This figure corresponds to the content of nutrients in fish fodder where there are 8 times as much P to N [Jonsson, Alanärä (2000): “Svensk fiskodlings närsaltsbelastning – faktiska nivåer och framtida utveckling”, Swedish University of Agricultural Sciences, Umeå]. The reliability of the figures is however not guaranteed.
