Detailed Purpose	Eco-profiles are intended primarily as building blocks for use in the construction of complete life cycle analyses. 1) Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2) Provide valuable inventory data for downstream users of plastics, such as packaging

	manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies. - Internal company benchmarking. - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occurred since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	- APME, Association of Plastics Manufacturers in Europe Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels .
Practitioner	Boustead, Ian - .
Reviewer	
Applicability	The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for SAN production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data on the SAN production processes have been supplied by 3 plants in 2 European countries. Data are probably fairly representative for production of SAN in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Note that emissions <0.5 mg (0.25 mg in data table) may be far below 0.5 mg in some cases. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, data for each production sequence (i.e. each plant + its specific suppliers) are calculated separately. The final result is the average of the results from the individual production sequences weighted by the output from each sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45.0 MJ/kg for crude oil, 38.8 MJ/m3 (54.1 MJ/kg) for natural gas, 28.0 MJ/kg for coal, 15.0 MJ/kg for lignite, 9.3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission (kg/MJ fuel) = 3.67 x {mass fraction of carbon in fuel}/{calorific value of fuel}. The following interpretations/changes from the original report have been made by Gunnar Mattson, ABB Corporate Research: - Nuclear energy has been recalculated to natural uranium resource. - Ferromanganese, Phosphate and Rutile have been recalculated to the corresponding amounts

	of Mn, P and Ti resources. - The energy resources Hydrogen and Sulphur have been excluded, as these parameters do not represent true natural resources. - Emissions and resources <0.5 mg (<1 mg in the Eco-profiles result tables) are presented as 0.25 mg, i.e. 1/2 of the ''<'' value. This is in accordance with common statistical procedure.
Notes	-- --- Changes made to the data set after publishing in SPINE@CPM--- >>> 29 October 2001 <<< Changes made by Gunnar Mattson, ABB Corporate Research: The general documentation of the data have been supplemented to improve the transparency and the consistency with other published data sets from the APME reports. The earlier published edition of the data set were named ''Production of SAN co-polymer granules'', and were documented by Sofia Medin, Electrolux Research and Innovation AB.

SPINE LCI dataset: Extraction to toluene APME

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Extraction to toluene APME
Functional Unit	1 kg of toluene
Functional Unit Explanation	Toluene, C6H5CH3, is an organic compound, liquid at room temperature. It is used as a solvent, in benzene production, and in TDI production (TDI is an intermediate in polyurethane production).
Process Type	Cradle to gate
Site	European average Used for identification of owner and/or site in Object of study under Technical system for activity
Sector	Materials and components
Owner	European average Used for identification of owner and/or site in Object of study under Technical system for activity
Technical system description	Production of toluene including all major operations from extraction of crude oil and gas to catalytic reforming of naphtha, solvent extraction and fractional distillation. Most toluene is produced directly from naphtha by catalytic reforming, a process in which naphthenic compounds in naphtha are dehydrogenated. The basic feedstock is thus converted into a mixture of products, mainly benzene, toluene and xylene; hence, the process is often called the BTX process. Benzene and the other aromatics are isolated in the pure state from the output of the reformer by solvent extraction and fractional distillation. The output of toluene is maximised if the naphtha feed is rich in ring compounds containing 7 carbon atoms. In addition to the mentioned sub-processes, the following major processes are included: Crude oil extraction and delivery; oil refining for naphtha (fractional distillation); natural gas extraction, processing and delivery; coal mining and delivery. Also electricity production and production of other raw materials have been included on a cradle to gate basis, i.e. all materials and energies have been traced back to the extraction of raw materials from the earth. Operating conditions: As the data are based on information from 10 plants in 4 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. Some more information about the processes are found in the ''Eco-profiles...'' reports for toluene and naphtha, and the Methodology report, which are available at APME''s web site http://lca.apme.org.

System Boundaries	
Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available.'' Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under their specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment. Emissions <0.5 mg were presented as <1 mg in the Eco-profiles result tables. In this activity, however, they are presented as 0.25 mg (1/2 of the maximum value 0.5 mg). Note that the actual values may be far below 0.5 mg in some cases. The energy resources Hydrogen and Sulphur have been excluded by GM, since these parameters do not represent true natural resources, but are reported as primary energy equivalents for energy balancing purposes. Probably they are included in other resources, e.g. crude oil and gas. Nuclear energy has been recalculated to natural uranium resource. Only Hydro energy and Unspecified energy are kept as primary energy equivalents in the flow table.
Time Boundary	Data refer to the years 1990-96. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Results are based on data for toluene production plants that produced 1,2 million tonnes. Data were supplied by 10 plants in 4 countries: Belgium, Germany, Italy and Netherlands. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For the intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides that plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included.) - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most other cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0.01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Methodology report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g., sulphuric acid is used as a drying agent for chlorine; therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process.

	- Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity.
Systems Expansions	Not applied. The amount of Recovered energy is reported as a negative primary energy equivalent input.

Flow Data

General Activity QMetaData

Date Conceived	1990 to 1996
Data Type	Derived, mixed
Represents	As no data for extraction of dolomite in Norway was obtained, figures from Swedish extraction of dolomite has been used.
Method	European average data. Results are based on data supplied by 10 production plants in 4 countries: Belgium, Germany, Italy and Netherlands. Their total production was 1.2 million tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45.0 MJ/kg for crude oil, 38.8 MJ/m3 (54.1 MJ/kg) for natural gas, 28.0 MJ/kg for coal, 15.0 MJ/kg for lignite, 9.3 MJ/kg for sulphur. Emissions and resources <0.5 mg have been assumed by Gunnar Mattson, ABB Corporate Research (GM) to be 0.25 mg, i.e. half the ''<'' values given, which is in accordance with common statistical procedure. The energy resources Hydrogen (0.07 MJ) and Sulphur (<0.01 MJ) have been excluded by GM, since these parameters do not represent true natural resources, but are reported as primary energy equivalents for energy balancing purposes. Probably they are included in other resources, e.g. crude oil and gas. Nuclear energy has been recalculated to natural uranium resource. Only Hydro energy and Unspecified energy are kept as primary energy equivalents in the flow table. 2001-01-19 SECRC/GM
Literature Reference	''Eco-profiles of the European plastics industry'', reports for toluene and naphtha. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. (APME = Association of Plastics Manufacturers in Europe)
Notes	In the result tables in the ''Eco-profiles...'' report, not only total fuels and feedstocks, emissions to air and water, and solid waste are presented, but also the amounts caused by fuel production, fuel use, transport, feedstock (only for fuels and feedstocks) and processes. As the APME substance nomenclature and the ABB database nomenclature sometimes differ, the original APME substance name is given within '''' in the flow metadata Notes field. Please note: Some other interpretations/changes have been made from the original report by Gunnar Mattson, ABB Corporate Research. See Method and AboutData for details.

Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as building blocks for use in the construction of complete life cycle analyses. 1) Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2) Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies. - Internal company benchmarking. - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occurred since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	- APME, Association of Plastics Manufacturers in Europe Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels .
Practitioner	Boustead, Ian - .

Applicability	The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for toluene production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data on the toluene production processes have been supplied by 10 plants in 4 European countries. Data are probably fairly representative for production of toluene in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Note that emissions <0.5 mg (0.25 mg in data table) may be far below 0.5 mg in some cases. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, data for each production sequence (i.e.

	each plant + its specific suppliers) are calculated separately. The final result is the average of the results from the individual production sequences weighted by the output from each sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45.0 MJ/kg for crude oil, 38.8 MJ/m3 (54.1 MJ/kg) for natural gas, 28.0 MJ/kg for coal, 15.0 MJ/kg for lignite, 9.3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO_2 emission. CO_2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO_2 emission (kg/MJ fuel) = 3.67 x {mass fraction of carbon in fuel}/{calorific value of fuel}. The following interpretations/changes from the original report have been made by Gunnar Mattson, ABB Corporate Research: - Nuclear energy has been recalculated to natural uranium resource. - Ferromanganese, Phosphate and Rutile have been recalculated to the corresponding amounts of Mn, P and Ti resources. - The energy resources Hydrogen and Sulphur have been excluded, as these parameters do not represent true natural resources. - Emissions and resources <0.5 mg (<1 mg in the Eco-profiles result tables) are presented as 0.25 mg, i.e. 1/2 of the ''<'' value. This is in accordance with common statistical procedure.
Notes	--- --- Changes made to the data set after publishing in SPINE@CPM--- >>> 29 October 2001 <<< Changes made by Gunnar Mattson, ABB Corporate Research The general documentation of the data have been supplemented, to improve the transparency and the consistency with other published data sets from the APME reports.

SPINE LCI dataset: Extraction to xylene APME

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Extraction to xylene APME
Functional Unit	1 kg of xylenes (mixed)
Functional Unit Explanation	Xylene, dimethylbenzene, C6H5(CH3)2, is obtained as a mixture of three isomers, o-xylene, m-xylene and p-xylene, all of which are liquid at room temperature. The mixture is used as an organic solvent; p-xylene is used as a raw material in the production of PET; o-xylene is used in the synthesis of phthalic anhydride.
Process Type	Cradle to gate
Site	European average Used for identification of owner and/or site in Object of study under Technical system for activity
Sector	Materials and components
Owner	European average Used for identification of owner and/or site in Object of study under Technical system for activity
Technical system description	Production of xylene including all major operations from extraction of crude oil and gas to catalytic reforming of naphtha, solvent extraction and fractional distillation. Most xylene is produced directly from naphtha by catalytic reforming, a process in which naphthenic compounds in naphtha are dehydrogenated. The basic feedstock is thus converted into a mixture of products, mainly benzene, toluene and xylene; hence, the process is often called the BTX process. Benzene and the other aromatics are isolated in the pure state from the output of the reformer by solvent extraction and fractional distillation. In addition to the mentioned sub-processes, the following major processes are included: Crude oil extraction and delivery; oil refining for naphtha (fractional distillation); natural gas extraction, processing and delivery; coal mining and delivery. Also electricity production and production of other raw materials have been included on a cradle to gate basis, i.e. all materials and energies have been traced back to the extraction of raw materials from the earth. Operating conditions: As the data are based on information from 8 plants in 4 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. Some more information about the processes are found in the ''Eco-profiles...'' reports for xylenes (mixed) and naphtha, and the Methodology report, which are available at APME''s web site http://lca.apme.org.

System Boundaries	
Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available.'' Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under their specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment. Emissions <0.5 mg were presented as <1 mg in the Eco-profiles result tables. In this

	activity, however, they are presented as 0.25 mg (1/2 of the maximum value 0.5 mg). Note that the actual values may be far below 0.5 mg in some cases. The energy resources Hydrogen and Sulphur have been excluded by GM, since these parameters do not represent true natural resources, but are reported as primary energy equivalents for energy balancing purposes. Probably they are included in other resources, e.g. crude oil and gas. Nuclear energy has been recalculated to natural uranium resource. Only Hydro energy and Unspecified energy are kept as primary energy equivalents in the flow table.
Time Boundary	Data refer to the years 1990-96. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Results are based on data for xylene production plants that produced 720000 tonnes. Data were supplied by 8 plants in 4 countries: Belgium, Germany, Italy and Netherlands. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For the intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides that plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included.) - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most other cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0.01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Methodology report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g., sulphuric acid is used as a drying agent for chlorine; therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity.
Systems Expansions	Not applied. The amount of Recovered energy is reported as a negative primary energy equivalent input.

Flow Data

General Activity QMetaData

Date Conceived	1990 to 1996
Data Type	Derived, mixed
Represents	

Method	European average data. Results are based on data supplied by 8 xylene production plants in 4 countries: Belgium, Germany, Italy and Netherlands. Their total production was 720000 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45.0 MJ/kg for crude oil, 38.8 MJ/m3 (54.1 MJ/kg) for natural gas, 28.0 MJ/kg for coal, 15.0 MJ/kg for lignite, 9.3 MJ/kg for sulphur. Emissions and resources <0.5 mg have been assumed by Gunnar Mattson ABB Corporate Research (GM) to be 0.25 mg, i.e. half the ''<'' values given, which is in accordance with common statistical procedure. The energy resources Hydrogen (0.04 MJ) and Sulphur (<0.01 MJ) have been excluded by GM, since these parameters do not represent true natural resources, but are reported as primary energy equivalents for energy balancing purposes. Probably they are included in other resources, e.g. crude oil and gas. Nuclear energy has been recalculated to natural uranium resource. Only Hydro energy and Unspecified energy are kept as primary energy equivalents in the flow table. 2001-05-31 SECRC/GM
Literature Reference	''Eco-profiles of the European plastics industry'', reports for xylenes (mixed) and naphtha. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. (APME = Association of Plastics Manufacturers in Europe)
Notes	In the result tables in the ''Eco-profiles...'' report, not only total fuels and feedstocks, emissions to air and water, and solid waste are presented, but also the amounts caused by fuel production, fuel use, transport, feedstock (only for fuels and feedstocks) and processes. As the APME substance nomenclature and the ABB database nomenclature sometimes differ, the original APME substance name is given within '''' in the flow metadata Notes field. Please note: Some other interpretations/changes have been made from the original report by Gunnar Mattson, ABB Corporate Research. See Method and AboutData for details.

About Inventory

Publication	"Eco-profiles of the European plastics industry", reports for xylenes (mixed) and naphtha. "Eco-profiles of plastics and related intermediates: Methodology", I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. (APME = Association of Plastics Manufacturers in Europe) The APME project co-ordinator: Vince Matthews. The members of the original independent expert panel: Ian Boustead, Paul Fink, Horst Langowski, Gustav Sundstrom. --- Editor: Data were entered into the SPINE format by Gunnar Mattsson, ABB Corporate Research, 2001-05-31. Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 29 October 2001 ---
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.

Detailed Purpose	Eco-profiles are intended primarily as building blocks for use in the construction of complete life cycle analyses. 1) Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2) Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies. - Internal company benchmarking. - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occurred since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.

Applicability	The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for xylene production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data on the xylene production processes have been supplied by 8 plants in 4 European countries. Data are probably fairly representative for production of xylene in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Note that emissions <0.5 mg (0.25 mg in data table) may be far below 0.5 mg in some cases. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, data for each production sequence (i.e. each plant + its specific suppliers) are calculated separately. The final result is the average of the results from the individual production sequences weighted by the output from each sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45.0 MJ/kg for crude oil, 38.8 MJ/m3 (54.1 MJ/kg) for natural gas, 28.0 MJ/kg for coal, 15.0 MJ/kg for lignite, 9.3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission (kg/MJ fuel) = 3.67 x

	{mass fraction of carbon in fuel}/{calorific value of fuel}. The following interpretations/changes from the original report have been made by Gunnar Mattson, ABB Corporate Research: - Nuclear energy has been recalculated to natural uranium resource. - Ferromanganese, Phosphate and Rutile have been recalculated to the corresponding amounts of Mn, P and Ti resources. - The energy resources Hydrogen and Sulphur have been excluded, as these parameters do not represent true natural resources. - Emissions and resources <0.5 mg (<1 mg in the Eco-profiles result tables) are presented as 0.25 mg, i.e. 1/2 of the ''<'' value. This is in accordance with common statistical procedure.

Technical system description	This dataset is intended to represent average data for production of kieserite used in production of fertilisers used in Sweden. Data have been given by Kali & Salz in Germany, no specific site has been studied. It is uncertain what techniques for extraction, beneficiation and grinding the data given by Kali & Salz represent. Kieserite is mined simultaneously with potash salt. The text below only gives generic information about extraction and beneficiation of potash salt, the data do not necessarily include these techniques. Information about different techniques of mining and beneficiation of potash salt: Salts deposits were formed by the evaporation of sea water, in which the most important ions are sodium (Na^+), potassium (K^+), magnesium (Mg^{2+}), calcium (Ca^{2+}), chloride (Cl^-) and sulphate (SO_4^{2-}) (Ullmann, vol. A 22, 1993). Beds of potassium-bearing salts, potash salts, exist in different shapes and at varying depths and the largest deposits are found in the United States, in Canada, in the former Soviet Union, in France and in Germany (Encyclopedia of Chemical Processing and Design, vol. 41, 1992, Patyk, 1996). The most important potash mineral is sylvinite, a mixture of sylvite (KCl) and halite or rock salt (NaCl) and so called hard salts, i.e. sylvite (KCl) and kieserite ($MgSO_4*H_2O$) (Phosphorus & Potassium, 1983; Patyk, 1996). Potash minerals are water-soluble and are therefore not found as an outcropping because of the effects of the weather and consequently surface indications of potash are rare or non-existent. Underground deposits have usually been discovered during oil exploration, since both oil and potash salt are sedimentary-type deposits and petroleum companies have been in a better financial position to conduct exploration than potash companies (Encyclopaedia of Chemical Processing and Design, vol. 41, 1992). About 95 % of the potassium salts is destined for the fertiliser industry and potassium chloride is the most important potassium compound in fertilisers (Phosphorus & Potassium, 1983, Patyk, 1996). Extraction of Potash Salt Shaft Mining Since mineral salts are very soluble any flow of water from the overlying strata, which

normally are water bearing, must be prevented. When sinking a shaft, this causes difficulties. A technique that involves freezing is currently used to avoid influx of water when sinking a mineshaft. The shaft itself is then protected from the water bearing rocks by the use of segments, made of cast iron or steel-reinforced concrete, bolted together to form rings. The shafts generally have a diameter of 5 -7 meters and the depth can be more than 1000 meters (Ullmann, vol. A 22, 1993).

The mining methods of potash ore depend on its purity and the shape of the deposits, the seams. In horizontal deposits the most common method of extraction is by cutting with heavy machinery and rooms are generally created by removing the salt and pillars are left to support the cover rocks and prevent them from collapsing. Another method of mining in horizontal deposits is longwall mining which is a caving operation (Ullmann, vol. A 22, 1993). Then machines with integral shearers are used, which can work at two different levels concurrently, with the upper face being mined some 25-30 meters ahead of the lower face. Mining faces are supported by self-advancing support systems with prop-chocks installed every 3-5 meters behind the shearer. The latter method was developed to increase the mine output since the room and pillar method left too much of the mineral unreclaimed (Phosphorus & Potassium, 1983).

In steeply dipping deposits the underhand stooping mining systems is the most favoured method. This involves the mining taking place simultaneously at different levels in the salt dome and the spiral roadways connecting the main levels. Often funnelling of ore is practised which implies that ore is dropped by a series of shafts to the lower level and then transported to the foot of the main shaft for removal. This way of transporting the ore is used to minimise the haulage (Phosphorus & Potassium, 1983).

The recovered material is transported by trackless diesel or cable-fed electric loaders. Sometimes conveyor belts and electric or diesel trains are used for transportation along underground roads. Since the introduction of diesel-powered machinery and vehicles, extra attention must be given to ventilation and therefore powerful fans are necessary. Finally, the ore is hoisted in the shaft in the large skips (Ullmann, vol. A 22, 1993).

Solution Mining

Solution mining is an alternative method of mining for potash ore, which makes it possible to exploit reserves where conventional mining is impossible, e.g. at great depth. This method eliminates high expense of sinking a shaft and can also be used where existing mine works are available but conventional mining methods are no longer feasible, even though extensive reserves still exist (Ullmann, vol. A 22, 1993). A reason why conventional mining is not possible anymore can be flooding in the mine, too much folding encountered or high occurrence of methane gas in the deposit (Encyclopedia of Chemical Processes and Design, vol. 41, 1992). The principles of the solution mining process are that water or an unsaturated solution of potassium chloride is passed through a system of boreholes into the potash seam. Potassium chloride and sodium chloride are dissolved and the almost saturated solution is then pumped up to the surface and fed to the production plant. The process is based on a series of patents and details have not yet been published (Ullmann, vol. A 22, 1993).

Extraction Methods Used in Different Countries

In Germany the potash production is five times the amount sold in the country (Patyk, 1996). The geological conditions vary widely between the northern and the southern regions and, consequently different mining methods are employed to extract the ore. The southern deposits, between the Fulda and Werra rivers, are at easily-accessible levels, but the seams are relatively thin; 1.3 -3.5 m. The potassium content is in the range 7 – 15 % K_2O. The ore is extracted by conventional mining and the room and pillar method is used in most cases. In the northern Hannover region the potash beds are steeply dipping and folded and the deposits have sometimes the shape of a dome (Ullmann, vol. A 22, 1993). Therefore they are less accessible, but the seam thickness vary between 4 and 30 meters and the K_2O content is between 13-14 %, on average 3,5 % higher than the southern deposits. The geological conditions in this region favour the underhand stooping mining system (Phosphorus & Potassium, 1983).

In France beds of potassium-bearing salts extend under the Plain of Alsace. Two sylvinite beds are found in three different basins. The upper bed has a K_2O content of 20-27 % and a thickness of about 1.5 meters, while the lower bed which contains 12-20 % K_2O is thicker, at about one to five meters. The room and pillar method has been practised for a long time, but in order to increase the mine output longwall is now predominantly used (Fertilizer Manual, 1998).

In the former Soviet Union the potash production is centred around three main regions; the Urals, Belarus and Ukraine (Fertilizer Manual, 1998). The room and pillar method has been extensively used, but nowadays longwall mining is the most frequent system of extraction (Encyclopedia of Chemical Processing and Design, vol. 41, 1992; Ullmann, vol. A 22, 1993).

The room and pillar method has been widely used for mining of potash ore in the United States. However, some mines has been converted to solution mining, e.g. a mine in Utah where conventional mining operations had to be terminated due to severe technological and geological problems (Encyclopedia of Chemical Processing and Design, vol. 41, 1992; Ullmann, vol. A 22, 1993).

In Canada solution mining and the room and pillar method are practised. Mining in Saskatchewan, Canada is relatively clean and straightforward since the evaporite beds are regular, tabular and relatively untilted (Encyclopedia of Chemical Processing and Design, vol. 41, 1992).

Beneficiation of Potash Ore
In order to increase the concentration of potassium chloride to 95 % three different beneficiation techniques are mainly applied in the potash industry; flotation, thermal dissolution-crystallisation or hot leaching and electrostatic separation (Patyk, 1996).

The salt minerals in potash ores are intergrown with other salt minerals to varying extents. The most important minerals are sylvinite, sylvite mixed with halite, and so-called hard salts, sylvite and kieserite (Patyk, 1996). Therefore the ore must be sufficiently reduced in size, so that individual components are accessible, before the minerals can be separated and the useful components recovered. Potash salts are relatively easily size-reduced by grinding. In the hot leaching process potassium chloride is extracted and must therefore not be occluded inside other minerals, which implies an upper grain size limit of 4-5 mm. For the mechanical processes, i.e. flotation and electrostatic separation, liberation of the minerals must be complete, which means that individual grains must consist as much as possible of pure minerals. For German sylvinite ores and hard salts, this is achieved by grinding to a maximum grain size of 0.8-1.0 mm, but for coarser sylvinite ores of, for example, Saskatchewan, Canada a size reduction to < 9 mm would give an adequate liberation (Ullmann, vol. A 22, 1993).

Flotation
Flotation essentially relies on the fact that fresh mineral surfaces can be induced to adopt either a hydrophobic or hydrophilic attitude in the solution by conditioning with specific surface chemicals. Air bubbles are then introduced into the solution and the mineral particles will, if they are hydrophobic, attach themselves to air bubbles at the air/water interface and float up to the top where they can be mechanically removed (Fertilizer Manual, 1998). Common collectors are hydrochloride and acetate salts of aliphatic amides with a carbon chain length of 12-24. Frothers are often added before the slurry enters the flotation cell (Encyclopedia of chemical Processes and Design, vol. 41, 1992). The flotation process has advantages over other processes, in particular the crystallisation process, in that total energy consumption is generally lower and maintenance and equipment depreciation charges generally less than for other comparable processes (Fertiliser Manual, 1998).

Dissolution-Crystallisation or Hot Leaching
The basis of the dissolution-crystallisation method of benificiation, even called the hot leaching process, lies in the fact that potassium chloride is very much more soluble in hot water than in cold, whereas sodium chloride is only slightly more soluble at 100°C than at 20°C. In solutions saturated with respect to both sodium and potassium chloride, sodium chloride is actually less soluble at higher temperatures. Firstly, the sylvinite ore is crushed and washed with cool, saturated sodium/potassium chloride solution. Clay is removed and the clarified solution is then heated and used to dissolve the potassium chloride in the washed ore. Any undissolved sodium chloride is discarded as tailings. Finally, the solution is cooled under vacuum, which results in the crystallisation of potassium chloride and the crystals are separated, washed and dried (Fertilizer Manual, 1998). The remaining brine, mostly sodium chloride, is recirculated and heat exchangers recover valuable heat. A major cost in this process is the heating of the cool mother liquid from the crystalliser before recycling it to the dissolution stage (Phosphorus & Potassium, 1983). However, this method was used before the introduction of flotation in the mid-1930s and it is to prefer when the ores are excessively high in either clay or carnallite (Encyclopedia of Chemical Processes and Design, vol. 41, 1992).

Electrostatic Separation
Electrostatic separation is a dry technique in which a mixture of minerals may be differentiated according to their electrical conductivity. For potash minerals, which are not naturally conductive, the separation must be preceded by a conditioning step that induces the minerals to carry electrostatic charges of different magnitude and, if possible, different polarities. In Germany, the researchers have developed a process for dry beneficiation of complex potash ores. Particle size, conditioning agents, and relative humidity are used in the electrostatic separation zones to separate ore into three fractions (Fertiliser Manual, 1998). The components are separated in stages, using up to four stages and the particles pass direct from one stage to another. The company that has developed this process, Kali und Salz GmbH, is silent about the process, but a stage seems to be two rows of tubes, 25 cm apart and 2.5 m long, at 100 kV direct current. Using this process for beneficiation, all the energy that is consumed when drying out the potash beneficiated by wet means is saved and tailings disposal problems associated with alternative wet separation processes eliminated (Encyclopedia of Chemical Processes and Design, vol. 41, 1992).

Methods of Beneficiation used in Different Countries
In Germany the hot leaching process is the dominating method of beneficiation of potash ores (Ullmann, vol. A 22, 1993). Electrostatic separation is also used to a large extent (Fertilizer Manual, 1998).

Flotation is used at one plant in France and the hot leaching process is practised at the two remaining ones (Fertilizer Manual, 1998; Encyclopedia of Chemical Processes and Design, vol. 41, 1992).

In Spain and in the United Kingdom flotation is used exclusively for the separation of potassium chloride from sodium chloride (Encyclopedia of Chemical Processes and Design, vol. 41, 1992).

In the former Soviet Union the hot leaching process is still a widely used method for beneficiation of potash ores, especially in old plants. Generally the flotation process is used in new installations, except when potash ores contain high levels of clay or when magnesium chloride levels exceed 30 % (Phosphorus & Potassium, 1983).

In Canada and in the United States flotation is predominantly used as the main product process, except for the two solution mines (Encyclopedia of Chemical Processes and Design, vol. 41, 1992). In some plants, especially in Canada small hot leaching plants are also operated, in which product fines are recrystallised or potassium chloride is extracted and crystallised from the flotation residues and clay slurries (Ullmann, vol. A 22, 1993).

Potassium chloride and potassium sulphate are also produced from brines on commercial basis from six sources in the world, including two lakes, the Great Salt Lake in Utah and the Dead Sea between Israel and Jordan; two subsurface brine sources, one in California and one in Utah; two solution mines, one in Utah and one in Saskatchewan, Canada. Potassium sulphate is produced from the Great Salt Lake and the subsurface brine in California and potassium chloride is produced from all brines except the one from Great Salt Lake. Brines from the sources in Saskatchewan and in California are concentrated in multiple-effect evaporators and crystals of the final product are grown in multiple-stage vacuum crystallisers. The brine from the other sources is concentrated by solar evaporation (Encyclopedia of Chemical Processes and Design, vol. 41, 1992).

Environmental Aspects
In addition to the consumption of energy, the main environmental problem of the potash industry is disposal of process waste (Ullmann, vol. A 22, 1993). When processing potash ore to saleable product three types of waste products are generated; liquid and solid salt tailings, insolubles or slimes and dust. Salt tailings are generally the major environmental concern and the composition of the waste depends on the type of ore treated. Waste from sylvinite processing consists mainly of halite, waste from treatment of hard salts are halite and kieserite and from treatment of carnallitic ore are halite and carnallite (Phosphorus & Potassium, 1983; Ullmann, vol. A 22, 1993). Concentrated salt is a toxic waste which does not decay and requires dilution in order to be non-toxic (Phosphorus & Potassium, 1983).

There are four methods for disposing of waste; stacking, backfilling, pumping into the ground and discharge into natural water systems (Ullmann, vol. A 22, 1993). Until recently, plants merely stacked their waste salts and slimes and injected the excess brine underground, or dumped both into the nearest river. New plants have been required to eliminate these practices (Fertlizer Manual, 1998). In case of stacking, measures must be taken so that salt solutions that run off the deposited material, such as solid salt tailings and insolubles, not harm the environment when they are absorbed into the ground. If the ground underneath the stack is not impermeable, layers of clay or plastic sheets must seal it. In Germany, the solid waste is formed into steep conical heaps in order to decrease the amount of run off water formed by rainfall and to minimise the required ground area. If mining methods are suitable and certain geological requirements are met solid waste can be backfilled in the mines. This is the main method of waste disposal in the potash works in the northern Germany, where the salt beds are steeply inclined and this method is also practised in some mines in Canada. However, backfilling is not possible for technical and economic reasons in most potash works (Ullmann, vol. A 22, 1993).

Under certain geological conditions it is possible to pump salt solutions back into the ground. For this purpose the formation used must possess sufficient porosity and permeability and must have no contact with water bearing formations. For example, in the Werra potash region of Germany large quantities of brines have been pumped into a porous dolomite layer. However, in this region the amount of brines produced has decreased drastically since the introduction of electrostatic separation of potash ore. This beneficiation process was developed in the aim of reducing the amount of liquid salt tailings (Ullmann, vol. A 22, 1993). Sea disposal is practised in the United Kingdom (Fertilizer Manual, 1998) and by one of the works in Canada and presents few major problems if the outlet is sufficiently far away from the coast. The potash works on the Dead Sea can dispose waste brine in the Dead Sea itself, without problems since the waste brine is more diluted than the water in the Dead Sea. For most potash works, waste brines must be disposed into natural flowing water since neither underground disposal nor disposal in seawater is possible. This is strictly regulated in most countries, but although, for example, the salt halt in the Werra River, Germany is very high due to the potash works in the eastern part of the Werra region (Ullmann, vol. A 22, 1993).

The only important atmospheric pollution caused by the production of potassium salts is dust emitted from the drying plant and from the handling of the ore and the products (Ullmann, vol. A 22, 1993). Such emissions contain primarily a mixture of potassium chloride and sodium chloride and deposition of the dust may be beneficial or hazardous to soil productivity depending on the level of emissions (Phosphorus & Potassium, 1983).

System Boundaries	
Nature Boundary	The system starts with extraction and ends with ground kieserite leaving the beneficiation site. Energy consumption for extraction and emissions from combustion of natural gas are not included.
Time Boundary	The data were given by Kali & Salz in 1998.
Geographical Boundary	The extraction, beneficiation and grinding takes place in Germany.
Other Boundaries	Energy consumption for extraction and emissions from combustion of natural gas are not included.
Allocations	Not applicable.
Systems Expansions	Not applicable.

Flow Data	
General Activity QMetaData	
Date Conceived	
Data Type	Derived, unspecified
Represents	
Method	Information was taken from personal communication with Mr Aselmeyer at Kali & Salz in Germany.
Literature Reference	Personal communication: Aselmeyer F-B (1998). Kali und Salz GmbH, Kassel, Germany. tel: +49-561-301-2224.
Notes	In the result tables in the ''Eco-profiles...'' report, not only total fuels and feedstocks, emissions to air and water, and solid waste are presented, but also the amounts caused by fuel production, fuel use, transport, feedstock (only for fuels and feedstocks) and processes. As the APME substance nomenclature and the ABB database nomenclature sometimes differ, the original APME substance name is given within '''' in the flow metadata Notes field. Please note: Some other interpretations/changes have been made from the original report by Gunnar Mattson, ABB Corporate Research. See Method and AboutData for details.

About Inventory	
Publication	Davis J, Haglund C (1999). ''Life Cycle Inventory (LCI) of Fertiliser Production - Fertiliser Products Used in Sweden and Western Europe''. SIK report no. 654. The Swedish Institute for Food and Biotechnology (SIK). Gothenburg, Sweden. -- Data documented by: Jennifer Davis, SIK (The Swedish Institute for Food and Biotechnology). Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The dataset is intended to be
General Purpose	To generate an inventory of emissions and use of resources due to the production of fertilisers used in Sweden.
Detailed Purpose	The purpose was not to compare production of different fertilisers with each other but to generate a thorough inventory of emissions and use of resources due to the production of fertilisers used in Sweden. The data are intended to constitute a useful basis of input information in life cycle assessments of food production systems. Production of kieserite is one step in the line of production of some of the fertilisers containing potassium produced in Sweden.
Commissioner	- SIK AB, The Swedish Institute for Food and Biotechnology Box 5401 SE-402 29 Gothenburg Sweden .
Practitioner	Davis, Jennifer and Caroline Haglund - SIK AB Box 5401 402 29 Gothenburg Sweden.
Reviewer	-

Applicability	The dataset is applicable for extraction, beneficiation and grinding of kieserite in Germany. It is included in aggregated datasets for production of fertilisers at Hydro Agri AB in Köping, Sweden (cradle to gate).
About Data	The data are given by Kali und salz in Germany. No information on process emissions during extraction, beneficiation and grinding was given.
Notes	Internal review of the report was performed by: Olle Ramnäs, CTH (Chalmers University of Technology), Berit Mattsson and Magnus Stadig, SIK (The Swedish Institute for Food and Biotechnology).

Technical system description	This dataset is intended to represent average data for production of potash salt used in production of fertilisers used in Sweden. Data have been given by Kali & Salz in Germany, no specific site has been studied. It is uncertain what techniques for extraction, beneficiation and grinding the data given by Kali & Salz represent. The text below only gives generic information about extraction and beneficiation of potash salt, the data do not necessarily include these techniques. Salts deposits were formed by the evaporation of sea water, in which the most important ions are sodium (Na+), potassium (K+), magnesium (Mg2+), calcium (Ca2+), chloride (Cl-) and sulphate (SO42-) (Ullmann, vol. A 22, 1993). Beds of potassium-bearing salts, potash salts, exist in different shapes and at varying depths and the largest deposits are found in the United States, in Canada, in the former Soviet Union, in France and in Germany (Encyclopedia of Chemical Processing and Design, vol. 41, 1992, Patyk, 1996). The most important potash mineral is sylvinite, a mixture of sylvite (KCl) and halite or rock salt (NaCl) and so called hard salts, i.e. sylvite (KCl) and kieserite (MgSO4*H2O) (Phosphorus & Potassium, 1983; Patyk, 1996). Potash minerals are water-soluble and are therefore not found as an outcropping because of the effects of the weather and consequently surface indications of potash are rare or non-existent. Underground deposits have usually been discovered during oil exploration, since both oil and potash salt are sedimentary-type deposits and petroleum companies have been in a better financial position to conduct exploration than potash companies (Encyclopaedia of Chemical Processing and Design, vol. 41, 1992). About 95 % of the potassium salts is destined for the fertiliser industry and potassium chloride is the most important potassium compound in fertilisers (Phosphorus & Potassium, 1983, Patyk, 1996). Extraction of Potash Salt Shaft Mining Since mineral salts are very soluble any flow of water from the overlying strata, which normally are water bearing, must be prevented. When sinking a shaft, this causes difficulties. A technique that involves freezing is currently used to avoid influx of water when sinking a mineshaft. The shaft itself is then protected from the water bearing rocks by the use of segments, made of cast iron or steel-reinforced concrete, bolted together to form rings. The shafts generally have a diameter of 5 -7 meters and the depth can be more than

1000 meters (Ullmann, vol. A 22, 1993).

The mining methods of potash ore depend on its purity and the shape of the deposits, the seams. In horizontal deposits the most common method of extraction is by cutting with heavy machinery and rooms are generally created by removing the salt and pillars are left to support the cover rocks and prevent them from collapsing. Another method of mining in horizontal deposits is longwall mining which is a caving operation (Ullmann, vol. A 22, 1993). Then machines with integral shearers are used, which can work at two different levels concurrently, with the upper face being mined some 25-30 meters ahead of the lower face. Mining faces are supported by self-advancing support systems with prop-chocks installed every 3-5 meters behind the shearer. The latter method was developed to increase the mine output since the room and pillar method left too much of the mineral unreclaimed (Phosphorus & Potassium, 1983).

In steeply dipping deposits the underhand stooping mining systems is the most favoured method. This involves the mining taking place simultaneously at different levels in the salt dome and the spiral roadways connecting the main levels. Often funnelling of ore is practised which implies that ore is dropped by a series of shafts to the lower level and then transported to the foot of the main shaft for removal. This way of transporting the ore is used to minimise the haulage (Phosphorus & Potassium, 1983).

The recovered material is transported by trackless diesel or cable-fed electric loaders. Sometimes conveyor belts and electric or diesel trains are used for transportation along underground roads. Since the introduction of diesel-powered machinery and vehicles, extra attention must be given to ventilation and therefore powerful fans are necessary. Finally, the ore is hoisted in the shaft in the large skips (Ullmann, vol. A 22, 1993).

Solution Mining

Solution mining is an alternative method of mining for potash ore, which makes it possible to exploit reserves where conventional mining is impossible, e.g. at great depth. This method eliminates high expense of sinking a shaft and can also be used where existing mine works are available but conventional mining methods are no longer feasible, even though extensive reserves still exist (Ullmann, vol. A 22, 1993). A reason why conventional mining is not possible anymore can be flooding in the mine, too much folding encountered or high occurrence of methane gas in the deposit (Encyclopedia of Chemical Processes and Design, vol. 41, 1992). The principles of the solution mining process are that water or an unsaturated solution of potassium chloride is passed through a system of boreholes into the potash seam. Potassium chloride and sodium chloride are dissolved and the almost saturated solution is then pumped up to the surface and fed to the production plant. The process is based on a series of patents and details have not yet been published (Ullmann, vol. A 22, 1993).

Extraction Methods Used in Different Countries

In Germany the potash production is five times the amount sold in the country (Patyk, 1996). The geological conditions vary widely between the northern and the southern regions and, consequently different mining methods are employed to extract the ore. The southern deposits, between the Fulda and Werra rivers, are at easily-accessible levels, but the seams are relatively thin; 1.3 -3.5 m. The potassium content is in the range 7 – 15 % K2O. The ore is extracted by conventional mining and the room and pillar method is used in most cases. In the northern Hannover region the potash beds are steeply dipping and folded and the deposits have sometimes the shape of a dome (Ullmann, vol. A 22, 1993). Therefore they are less accessible, but the seam thickness vary between 4 and 30 meters and the K2O content is between 13-14 %, on average 3,5 % higher than the southern deposits. The geological conditions in this region favour the underhand stooping mining system (Phosphorus & Potassium, 1983).

In France beds of potassium-bearing salts extend under the Plain of Alsace. Two sylvinite beds are found in three different basins. The upper bed has a K2O content of 20-27 % and a thickness of about 1.5 meters, while the lower bed which contains 12-20 % K2O is thicker, at about one to five meters. The room and pillar method has been practised for a long time, but in order to increase the mine output longwall is now predominantly used (Fertilizer Manual, 1998).

In the former Soviet Union the potash production is centred around three main regions; the Urals, Belarus and Ukraine (Fertilizer Manual, 1998). The room and pillar method has been extensively used, but nowadays longwall mining is the most frequent system of extraction (Encyclopedia of Chemical Processing and Design, vol. 41, 1992; Ullmann, vol. A 22, 1993).

The room and pillar method has been widely used for mining of potash ore in the United States. However, some mines has been converted to solution mining, e.g. a mine in Utah where conventional mining operations had to be terminated due to severe technological and geological problems (Encyclopedia of Chemical Processing and Design, vol. 41, 1992; Ullmann, vol. A 22, 1993).

In Canada solution mining and the room and pillar method are practised. Mining in Saskatchewan, Canada is relatively clean and straightforward since the evaporite beds are regular, tabular and relatively untilted (Encyclopedia of Chemical Processing and Design, vol. 41, 1992).

Beneficiation of Potash Ore

In order to increase the concentration of potassium chloride to 95 % three different beneficiation techniques are mainly applied in the potash industry; flotation, thermal dissolution-crystallisation or hot leaching and electrostatic separation (Patyk, 1996).

The salt minerals in potash ores are intergrown with other salt minerals to varying extents. The most important minerals are sylvinite, sylvite mixed with halite, and so-called hard salts, sylvite and kieserite (Patyk, 1996). Therefore the ore must be sufficiently reduced in size, so that individual components are accessible, before the minerals can be separated and the useful components recovered. Potash salts are relatively easily size-reduced by grinding. In the hot leaching process potassium chloride is extracted and must therefore not be occluded inside other minerals, which implies an upper grain size limit of 4-5 mm. For the mechanical processes, i.e. flotation and electrostatic separation, liberation of the minerals must be complete, which means that individual grains must consist as much as possible of pure minerals. For German sylvinite ores and hard salts, this is achieved by grinding to a maximum grain size of 0.8-1.0 mm, but for coarser sylvinite ores of, for example, Saskatchewan, Canada a size reduction to < 9 mm would give an adequate liberation (Ullmann, vol. A 22, 1993).

Flotation

Flotation essentially relies on the fact that fresh mineral surfaces can be induced to adopt either a hydrophobic or hydrophilic attitude in the solution by conditioning with specific surface chemicals. Air bubbles are then introduced into the solution and the mineral particles will, if they are hydrophobic, attach themselves to air bubbles at the air/water interface and float up to the top where they can be mechanically removed (Fertilizer Manual, 1998). Common collectors are hydrochloride and acetate salts of aliphatic amides with a carbon chain length of 12-24. Frothers are often added before the slurry enters the flotation cell (Encyclopedia of chemical Processes and Design, vol. 41, 1992). The flotation process has advantages over other processes, in particular the crystallisation process, in that total energy consumption is generally lower and maintenance and equipment depreciation charges generally less than for other comparable processes (Fertiliser Manual, 1998).

Dissolution-Crystallisation or Hot Leaching

The basis of the dissolution-crystallisation method of benificiation, even called the hot leaching process, lies in the fact that potassium chloride is very much more soluble in hot water than in cold, whereas sodium chloride is only slightly more soluble at 100°C than at 20°C. In solutions saturated with respect to both sodium and potassium chloride, sodium chloride is actually less soluble at higher temperatures. Firstly, the sylvinite ore is crushed and washed with cool, saturated sodium/potassium chloride solution. Clay is removed and the clarified solution is then heated and used to dissolve the potassium chloride in the washed ore. Any undissolved sodium chloride is discarded as tailings. Finally, the solution is cooled under vacuum, which results in the crystallisation of potassium chloride and the crystals are separated, washed and dried (Fertilizer Manual, 1998). The remaining brine, mostly sodium chloride, is recirculated and heat exchangers recover valuable heat. A major cost in this process is the heating of the cool mother liquid from the crystalliser before recycling it to the dissolution stage (Phosphorus & Potassium, 1983). However, this method was used before the introduction of flotation in the mid-1930s and it is to prefer when the ores are excessively high in either clay or carnallite (Encyclopedia of Chemical Processes and Design, vol. 41, 1992).

Electrostatic Separation

Electrostatic separation is a dry technique in which a mixture of minerals may be differentiated according to their electrical conductivity. For potash minerals, which are not naturally conductive, the separation must be preceded by a conditioning step that induces the minerals to carry electrostatic charges of different magnitude and, if possible, different polarities. In Germany, the researchers have developed a process for dry beneficiation of complex potash ores. Particle size, conditioning agents, and relative humidity are used in the electrostatic separation zones to separate ore into three fractions (Fertiliser Manual, 1998). The components are separated in stages, using up to four stages and the particles pass direct from one stage to another. The company that has developed this process, Kali und Salz GmbH, is silent about the process, but a stage seems to be two rows of tubes, 25 cm apart and 2.5 m long, at 100 kV direct current. Using this process for beneficiation, all the energy that is consumed when drying out the potash beneficiated by wet means is saved and tailings disposal problems associated with alternative wet separation processes eliminated (Encyclopedia of Chemical Processes and Design, vol. 41, 1992).

Methods of Beneficiation used in Different Countries

In Germany the hot leaching process is the dominating method of beneficiation of potash ores (Ullmann, vol. A 22, 1993). Electrostatic separation is also used to a large extent (Fertilizer Manual, 1998).

Flotation is used at one plant in France and the hot leaching process is practised at the two remaining ones (Fertilizer Manual, 1998; Encyclopedia of Chemical Processes and Design, vol. 41, 1992).

In Spain and in the United Kingdom flotation is used exclusively for the separation of potassium chloride from sodium chloride (Encyclopedia of Chemical Processes and Design, vol. 41, 1992).

In the former Soviet Union the hot leaching process is still a widely used method for beneficiation of potash ores, especially in old plants. Generally the flotation process is used in new installations, except when potash ores contain high levels of clay or when magnesium chloride levels exceed 30 % (Phosphorus & Potassium, 1983).

In Canada and in the United States flotation is predominantly used as the main product process, except for the two solution mines (Encyclopedia of Chemical Processes and Design, vol. 41, 1992). In some plants, especially in Canada small hot leaching plants are also operated, in which product fines are recrystallised or potassium chloride is extracted and crystallised from the flotation residues and clay slurries (Ullmann, vol. A 22, 1993).

Potassium chloride and potassium sulphate are also produced from brines on commercial basis from six sources in the world, including two lakes, the Great Salt Lake in Utah and the Dead Sea between Israel and Jordan; two subsurface brine sources, one in California and one in Utah; two solution mines, one in Utah and one in Saskatchewan, Canada. Potassium sulphate is produced from the Great Salt Lake and the subsurface brine in California and potassium chloride is produced from all brines except the one from Great Salt Lake. Brines from the sources in Saskatchewan and in California are concentrated in multiple-effect evaporators and crystals of the final product are grown in multiple-stage vacuum crystallisers. The brine from the other sources is concentrated by solar evaporation (Encyclopedia of Chemical Processes and Design, vol. 41, 1992).

Environmental Aspects
In addition to the consumption of energy, the main environmental problem of the potash industry is disposal of process waste (Ullmann, vol. A 22, 1993). When processing potash ore to saleable product three types of waste products are generated; liquid and solid salt tailings, insolubles or slimes and dust. Salt tailings are generally the major environmental concern and the composition of the waste depends on the type of ore treated. Waste from sylvinite processing consists mainly of halite, waste from treatment of hard salts are halite and kieserite and from treatment of carnallitic ore are halite and carnallite (Phosphorus & Potassium, 1983; Ullmann, vol. A 22, 1993). Concentrated salt is a toxic waste which does not decay and requires dilution in order to be non-toxic (Phosphorus & Potassium, 1983).

There are four methods for disposing of waste; stacking, backfilling, pumping into the ground and discharge into natural water systems (Ullmann, vol. A 22, 1993). Until recently, plants merely stacked their waste salts and slimes and injected the excess brine underground, or dumped both into the nearest river. New plants have been required to eliminate these practices (Fertlizer Manual, 1998). In case of stacking, measures must be taken so that salt solutions that run off the deposited material, such as solid salt tailings and insolubles, not harm the environment when they are absorbed into the ground. If the ground underneath the stack is not impermeable, layers of clay or plastic sheets must seal it. In Germany, the solid waste is formed into steep conical heaps in order to decrease the amount of run off water formed by rainfall and to minimise the required ground area. If mining methods are suitable and certain geological requirements are met solid waste can be backfilled in the mines. This is the main method of waste disposal in the potash works in the northern Germany, where the salt beds are steeply inclined and this method is also practised in some mines in Canada. However, backfilling is not possible for technical and economic reasons in most potash works (Ullmann, vol. A 22, 1993).

Under certain geological conditions it is possible to pump salt solutions back into the ground. For this purpose the formation used must possess sufficient porosity and permeability and must have no contact with water bearing formations. For example, in the Werra potash region of Germany large quantities of brines have been pumped into a porous dolomite layer. However, in this region the amount of brines produced has decreased drastically since the introduction of electrostatic separation of potash ore. This beneficiation process was developed in the aim of reducing the amount of liquid salt tailings (Ullmann, vol. A 22, 1993). Sea disposal is practised in the United Kingdom (Fertilizer Manual, 1998) and by one of the works in Canada and presents few major problems if the outlet is sufficiently far away from the coast. The potash works on the Dead Sea can dispose waste brine in the Dead Sea itself, without problems since the waste brine is more diluted than the water in the Dead Sea. For most potash works, waste brines must be disposed into natural flowing water since neither underground disposal nor disposal in seawater is possible. This is strictly regulated in most countries, but although, for example, the salt halt in the Werra River, Germany is very high due to the potash works in the eastern part of the Werra region (Ullmann, vol. A 22, 1993).

The only important atmospheric pollution caused by the production of potassium salts is dust emitted from the drying plant and from the handling of the ore and the products (Ullmann, vol. A 22, 1993). Such emissions contain primarily a mixture of potassium chloride and sodium chloride and deposition of the dust may be beneficial or hazardous to soil productivity depending on the level of emissions (Phosphorus & Potassium, 1983).

System Boundaries

Nature Boundary	The system starts with extraction of potash salt and ends with potassium chloride leaving the factory gate. Energy consumption for extraction and emissions from combustion of natural gas are not included.
Time Boundary	The data were given by Kali & Salz in 1998.
Geographical Boundary	The extraction, beneficiation and grinding take place in Germany.
Other Boundaries	Energy consumption for extraction and emissions from combustion of natural gas are not included.
Allocations	Not applicable.
Systems Expansions	Not applicable.

About Inventory

Publication	Davis J, Haglund C (1999). ''Life Cycle Inventory (LCI) of Fertiliser Production - Fertiliser Products Used in Sweden and Western Europe''. SIK report no. 654. The Swedish Institute for Food and Biotechnology (SIK). Gothenburg, Sweden. -- Data documented by: Jennifer Davis, SIK (The Swedish Institute for Food and Biotechnology). Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The dataset is intended to be
General Purpose	To generate an inventory of emissions and use of resources due to the production of fertilisers used in Sweden.
Detailed Purpose	The purpose was not to compare production of different fertilisers to each other but to generate a thorough inventory of emissions and use of resources due to the production of fertilisers used in Sweden. The data are intended to constitute a useful basis of input information in life cycle assessments of food production systems. Production of potasssium chloride is one step in the line of production of fertilisers containing potassium produced in Sweden.
Commissioner	- SIK AB, The Swedish Institute for Food and Biotechnology Box 5401 SE-402 29 Gothenburg Sweden .
Practitioner	Davis, Jennifer and Caroline Haglund - SIK AB Box 5401 402 29 Gothenburg Sweden.
Reviewer	-
Applicability	The dataset is applicable for extraction, beneficiation and grinding of potash salt in Germany. It is included in aggregated datasets for production of fertilisers at Hydro Agri AB in Köping (cradle to gate).
About Data	The data are given by Kali und salz in Germany. No information on process emissions during extraction, beneficiation and grinding was given.

Notes	Internal review of the report was performed by: Olle Ramnäs, CTH (Chalmers University of Technology), Berit Mattsson and Magnus Stadig, SIK (The Swedish Institute for Food and Biotechnology).

SPINE LCI dataset: Fabrication of oil filters

Administrative	
Finished	Y
Date Completed	2002-12-12
Copyright	
Availability	Public

Technical System	
Name	Fabrication of oil filters
Functional Unit	0.706 kg of filter
Functional Unit Explanation	The oil filter HC 8904 FKP 16Z weighs 0.706 kg.
Process Type	Cradle to gate
Site	Tipperary, Ireland
Sector	Materials and components
Owner	Tipperary, Ireland
Technical system description	Fabrication of oil filters is described in this data set. The filter is used to clean circulating oil in a lubricating system. The oil filter HC 8904 FKP 16Z is made of PA 66, POM and PET, glass and teflon. It is coreless which means that no part of it is made of metal, it is thouroughly plastic.

System Boundaries	
Nature Boundary	The plastic raw material as well as the finished filters comes from the technosphere. Emissions are not included due to lack of data.
Time Boundary	Data is collected autumn 2002. No changes are planned for the nearest future.
Geographical Boundary	The production site is in Ireland.
Other Boundaries	No transports are included.
Allocations	Not applicable
Systems Expansions	Not applicable

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Thechnology, December 2002. -------------- Data documented by Sandra Häggström, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-03-21.
Intended User	Product developer at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The purpose for our study is to compare a coated roller bearing to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll and is lubricated with a circulating oil system in both cases. The circulating oil is cleaned using filters from Pall, also in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Sandra Häggström - .
Reviewer	Olle Ramnäs -
Applicability	The data is applicable for coreless oil filters.
About Data	The data is collected by personal communication with Mike Day, Pall Corporation.
Notes	

SPINE LCI dataset: Ferry

Administrative	
Finished	Y
Date Completed	1998 08
Copyright	NTM
Availability	Public

Technical System	
Name	Ferry
Functional Unit	1 tonkm
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 50 % for tankers, 80 % for RoRo vessles and 60% for other vessles. This is concidered representative for traffic to/from Sweden. *empty trips are included.*
Process Type	Gate to gate
Site	Sweden
Sector	Sea transport

Owner	Sweden
Technical system description	Operation of ferry, of the type that plies to Denmark and Finland, with a utilisation level of 60% by weight.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO_2 -tax regulated CO_2. Diffuse emissions to air, emissions to water (e.g. discharges of oil) and emissions to ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents the fleet in 1999.
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 50 % for tankers, 80% for RoRo vessles and 60% for other vessles 60% (including empty trips) *Parameters not considered* -Driving technique -External conditions e.g. climate etc. -Maintenance level of the vessel *Excluded subsystems* -Precombustion, i.e. production and distribution of the fuel. -Maintenance of the vessel (e.g. use of anti fouling) -After-treatment of the vessel -Handling of production rests
Allocations	The energy use and emissions have been allocated between passengers and goods according to a method described in Sjöbris A. Flodström, E.''Emissions och energivärderingsprinciper för transportsystem'' KFB rapport 1994:9, 1994 The method is based on the argument that if there were no passengers, the cargo would be transported with a RoRo vessel of the same size. The goods is charged with the amount of energy use and emissions if it had been transported with a RoRo vessel of the same size, and the passengers are charged with the remaining energy use and emissions. The cargo then account for approx. 20 % of the total energy use and emissions of the ferry.
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1998 - 09
Data Type	Derived, unspecified
Represents	NTM
Method	All vessels larger than 300 tons gross tonnage in the Swedish Shipowners' Association's register have been used as a basis for the data For each individual ship, the load capacity (in dwt), installed engine effect (in kW) (Redareföreningen 1995) and speed (in knots) have been used as a basis. The emissions have been calculated on the basis of the distribution of low and high revolution engines among the different size classes, and the emission factors of the engines (Alexandersson et al 1991), see table below. The energy use has been calculated with the assumption of an oil consumption of 200 g/kWh for both low and medium revolution engines. The emisson factors below are given in g/kWh, where kWh refer to mechanical work done by the engine. Engine type Load NOx CO CO2 THC PM Low rev 80% 17,7 0,2 600 0,8 0,9 Medium rev 80% 14 1 620 0,2 0,4 The utilisation levels used in these calculations are as follows: Tank 0,5 Bulk 0,6 RoRo 0,8 LoLo 0,6 Ferry 0,6 Others 0,6 The calculations of emissions from shipping are made according to the following principle: emission factor = spec.emission x effect x 1 x 1 speed load capacity utilisation level The *quantity value* for all parameters is an average of all vessels in the population. The *minimum value* corresponds to the individual with the lowest energy use and emissions in the population, and the *maximum value* to the individual with the largest energy use and emissions in the population.
Literature Reference	Alexandersson, A., *Sjöfartens utsläpp av avgaser*, MariTerm, TFB-rapport 1991:18 Demker, G. et al. *Miljöeffekter av transportmedelsval för godstransporter*, MariTerm, KFB-rapport, 1994:6 *Skeppsregister 1995*, Swedish Shipowner Association Sjöbris, A., Flodström, E. *Emissions och energivärderingsprinciper för transportsystem*, MariTerm, KFB-rapport 1994:9 *Lloyds list*, 1996
Notes	The energy use and emissions from ferries vary greatly. The result depend on calculation method, size of the ship, speed, route, age of the ship, fuel etc. Swedish Shipowners Assossiation are working on an updated and more detailed version of emission data from ferries.

Flow Table and Specific Meta Data

About Inventory

Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value

	since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	Sörheim, Elisabet - Swedish Shipowners Association .
Reviewer	None, to be reviewed. -
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vessel, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. Vessels are individuals, which means that the energy use and emissions for different vessels at a given size may vary greatly. The vessels are generally optimised for the shipping route on which it will operate and the cargo it will carry. Generally, smaller vessels in Swedish traffic operate shorter routes, while larger vessels are used for transports to the continent and transocean transports. Data for the individual vessel performing the transport should be used when possible. Data for Swedish flagged vessels that are members of the Swedish Shipowners´ Association may be obtained from Elisabeth Sörheim at the Swedish Shipowners´ Association or from the operators. ***Type of vessels*** *Cargo Vessles* - includes all vessels except RoRo vessels and ferries. Cargo Vessles thus include a large variety of different vessels; tankers, container ships, LoLo vessels, bulk vessels, vessels built for a special route etc. Cargo Vessles are mainly used for transportation of heavy goods over large distances. The energy use for tankers is generally lower than for other Cargo vessles. *RoRo vessels* are used for transportation of different types of load carriers such as trailers, containers etc. The cargo is rolled on the vessel. RoRo vessels generally operate at a higher speed than regular Cargo vessles. *Ferries* carry both passengers and goods. The goods are carried in trucks, trailers or trains. ***Fuel*** The fuel quality vary to a large extent between different vessels. Smaller vessels that only operate on Swedish routes generally use cleaner fuels. The main part of freighters in Swedish traffic use heavy fuel oil, with a sulphur content of 2,6 %. Small coastal freighters may however use gas oil with sulphur content of 0,1 %. Gas oil is the most refined type of fuel used in vessels (the maximum sulphur content is 1,5 %). In ferries, low sulphur fuel with sulphur content of 0,5 % is generally used. ***Reduction of emissions*** The data does not assume the use of any emission reducing measures. Different measures may be taken to reduce the emissions, e.g. water injection may reduce the emissions of NOx by 50%, and adjustments of the engine may reduce NOx emissions by 30 %. Catalytic converters may reduce NOx emissions by 90-100% and HC by 70-80%. Emissions of particles and HC are also reduced. Installation of catalytic converters is however a large investment for the shipowners. There are at present only a few vessels in Swedish traffic that has installed catalytic converters. The other measures constitute a smaller investment, and it is anticipated that the shipowners will chose these techniques to reduce emissions. ***Bulky goods*** Vessels generally handle transportation of large heavy goods over long distances. Some bulky goods are however transported by sea, primarily by RoRo vessels and ferries. The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Travelled distance*** The travelled distance of the goods may be estimated using a Nautic almanac, Lloyd. Since the utilisation level includes empty trips, no compensation in the distance for empty trips needs to be done. ***International sea transports*** When using the data for international traffic, the sulphur emissions should be adjusted, since the fuel quality may vary. Representative sulphur content of fuel used in international traffic is 3,3 %. The energy use and emissions of other parameters may also vary to a large extent depending on the quality of the fuel. The utilisation levels used in these calculations are as follows: Tank 0,5 Bulk 0,6 RoRo 0,8 LoLo 0,6 Ferry 0,6 Others 0,6

About Data	Data have been calculated on the basis of the load capacity (in dwt), installed engine effect (in kW) (Redareföreningen) and speed (in knots) (Lloyds) of each individual ship. Emissions to air per tonkm have been calculated by using the emission factors of the engines (Alexandersson et.al. 1991), see table below, and by knowing the relation of low and medium revolution engines to different sizes of ships. The emisson factors below are given in g/kWh, where kWh refer to mechanical work done by the engine. Engine type Load NOx CO CO2 THC PM Low rev 80% 17,7 0,2 600 0,8 0,9 Medium rev 80% 14 1 620 0,2 0,4 The energy consumption has been calculated by the assumption of an oil consumption of 200g/kWh for both low and medium revolution engines. The sulphurous content of the fuel is assumed to be 0.5% for ferries (Sjöbris 1994). N.B. In this example, the load carrier is also counted as load! See also: Allocations.
Notes	The person stated as ''Practitioner'' is the contact person for the data for transportation by boat in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: Ferry, 700-7000 tonnes

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Ferry, 700-7000 tonnes
Functional Unit	1 tonkm, 60 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 60%. An utilisation level of 60% is representative for Swedish domestic traffic if *empty trips are included.*
Process Type	Unit operation
Site	Sweden
Sector	Sea transport
Owner	Sweden
Technical system description	Operation i.e. propulsion of Swedish flagged ferries carrying both passengers and cargo, which are members of the Swedish Shipowners´ Association. The loading capacity is 700 - 7000 tonnes.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water (e.g. discharges of oil) and emissions to ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents the fleet in 1997
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 60% (including empty trips). *Parameters not considered* -Driving technique -External conditions e.g. climate etc. -Maintenance level of the vessel *Excluded subsystems* -Precombustion, i.e. production and distribution of the fuel. -Maintenance of the vessel (e.g. use of anti fouling) -After-treatment of the vessel -Handling of production rests
Allocations	The energy use and emissions have been allocated between passengers and goods according to a method described in Sjöbris A. Flodström, E.''Emissions och energivärderingsprinciper för transportsystem'' KFB rapport 1994:9, 1994 The method is based on the argument that if there were no passengers, the cargo would be transported with a RoRo vessel of the same size. The goods is charged with the amount of energy use and emissions if it had been transported with a RoRo vessel of the same size, and the passengers are charged with the remaining energy use and emissions. The cargo then account for approx. 20 % of the total energy use and emissions of the ferry.
Systems Expansions	N/A

Flow Data	
General Activity QMetaData	
Date Conceived	1990-01-01 - 1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The basis for the data are all Swedish flagged ferries, which are members of the Swedish Shipowners' Association. The *quantity value* for all parameters is an average of all vessels in the population. The *minimum value* corresponds to the individual with the lowest energy use and emissions in the population, and the *maximum value* to the individual with the largest energy use and emissions in the population. The *utilisation level* with regard to weight is 60%, based on Demker et al. The data is allocated between the passengers and goods, 20 % of the energy use and emissions were allocated to the goods (for further information see Allocations). The energy use and emissions per tonkm for each vessel was calculated (see Specific QMetaData for each flow). For each vessel, the loading capacity was stated in deadweight tonnes (Skeppsregister 1995), installed engine power in kW (Skeppsregister 1995) and speed in knots (Lloyds list). The share of two-stroke and four-stroke engines in each vessel was determined by the size of the vessel according to Alexandersson. All vessels in the population were then used to calculate an average value.
Literature Reference	Alexandersson, A., *Sjöfartens utsläpp av avgaser*, MariTerm, TFB-rapport 1991:18 Demker, G. et al. *Miljöeffekter av transportmedelsval för godstransporter*, MariTerm, KFB-rapport, 1994:6 *Skeppsregister 1995*, Swedish Shipowner Association Sjöbris, A., Flodström, E. *Emissions och energivärderingsprinciper för transportsystem*, MariTerm, KFB-rapport 1994:9 *Lloyds list*, 1996
Notes	The energy use and emissions from ferries vary greatly. The result depend on calculation method, size of the ship, speed, route, age of the ship, fuel etc. Swedish Shipowners Assossiation are working on an updated and more detailed version of emission data from ferries.

About Inventory	
Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 --- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Elisabeth Sörheim, Swedish Shipowners' Association, contact person for sea transports in the work of NGM ---
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Sörheim, Elisabeth - The Swedish Shipowners Association, Box 53046, S-400 14 Göteborg .
Reviewer	
Applicability	*The data should be used with great care.* The distribution between goods and passengers may vary to a large extent between different ferries. The choice of allocation will have a large influence on the data. ***The Swedish Shipowners´ Association recommends that data for RoRo vessels should be used when considering transport by ferry.*** The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vessel, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. Vessels are individuals, which means that the energy use and emissions for different vessels at a given size may vary greatly. The vessels are generally optimised for the shipping route on which it will operate and the cargo it will carry. Generally, smaller vessels in Swedish traffic operate shorter routes, while larger vessels are used for transports to the continent and transocean transports. Data for the individual vessel performing the transport should be used when possible. Data for Swedish flagged vessels that are members of the Swedish Shipowners´ Association may be obtained from Elisabeth Sörheim at the Swedish Shipowners´ Association. ***Type of vessels*** *Freighters* - includes all vessels except RoRo vessels and ferries. Freighters thus include a large variety of different vessels; tankers, container ships, LoLo vessels, bulk vessels, vessels built for a special route etc. Freighters are mainly used for transportation of heavy goods over large distances. The energy use for tankers is generally lower than for other

	freighters. *RoRo vessels* are used for transportation of different types of load carriers such as trailers, containers etc. The cargo is rolled on the vessel. RoRo vessels generally operate at a higher speed than regular freighters. *Ferries* carry both passengers and goods. The goods are carried in trucks or trains. ***Fuel*** The fuel quality may vary to a large extent between different vessels. Smaller vessels that only operate on Swedish routes generally use better fuels. The main part of freighters in Swedish traffic use heavy fuel oil, with a sulphur content of 2,6 %. Small coastal freighters may however use gas oil with sulphur content of 0,1 %. Gas oil is the most refined type of fuel used in vessels (the maximum sulphur content is 1,5 %). In ferries, low sulphur fuel with sulphur content of 0,5 % is generally used. Differentiated harbour dues on sulphur and NOx emissions were introduced in Sweden 1 January 1998. This will probably result in use of fuels of a better quality, primarily in ferries but also other freighters. ***Reduction of emissions*** The data does not assume the use of any emission reducing measures. Different measures may be taken to reduce the emissions, e.g. water injection may reduce the emissions of NOx by 50%, and adjustments of the engine may reduce NOx emissions by 30 %. Catalytic converters may reduce NOx emissions by 90-100% and HC by 70-80%. Emissions of particles and HC are also reduced. Installation of catalytic converters is however a large investment for the shipowners. There are at present only a few vessels in Swedish traffic that has installed catalytic converters. The other measures constitute a smaller investment, and it is anticipated that the shipowners will chose these techniques to reduce emissions. ***Bulky goods*** Vessels generally handle transportation of large heavy goods over long distances. Some bulky goods are however transported by sea, primarily by RoRo vessels and ferries. The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Travelled distance*** The travelled distance of the goods may be estimated using a Nautic almanac, Lloyd. Since the utilisation level includes empty trips, no compensation in the distance for empty trips needs to be done. ***International sea transports*** When using the data for international traffic, the sulphur emissions should be adjusted, since the fuel quality may vary. Representative sulphur content of fuel used in international traffic is 3,3 %. The energy use and emissions of other parameters may also vary to a large extent depending on the quality of the fuel.
About Data	The data for emissions is derived from specific emission factors for the engine at a constant 80 % engine load. No test cycle was used to obtain the emission factors. There is however a small need for test cycles, since vessels generally operate at constant load on the engine during the sail. The fact that the engine load sometimes is lower than 80 % i.e. when sailing to and from the harbour has been neglected. This part is generally small but complicated. The calculation model may be used to calculate the energy use and emissions for a specific vessel if the loading capacity, installed engine power etc. is known. This information may be obtained from Skeppsregister. See QMetaData for details.
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Ferry, 700-7000 tonnes, future

Flow Data	
General Activity QMetaData	
Date Conceived	1997-01-01

Data Type	Derived, unspecified
Represents	NTM
Method	The energy use and emissions was calculated using *assumptions* on energy saving and emission reducing actions together with data for existing individual vessels with the *lowest energy use and emissions* within the population of Swedish flagged ferries, which are members of the Swedish Shipowners' Association. The utilisation level with regard to weight is 60 %. The data is allocated between the passengers and goods, 20 % of the energy use and emissions were allocated to the goods (for further information see Allocations). The assumptions were given by the Swedish Shipowners' Association. The data for energy use and emissions for the vessels that was the basis for the calculation, and a description on how the data was obtained, can be found in the activity with ObjectOfStudy.Name: *Ferry, 700-7000 tonnes* (in this database) or in ''Energi- och emissionsuppgifter för godstransporter''. The minimum value for the energy use and emissions was used in the calculation. The following percentages for the reduction of energy use and emissions was used in the calculation: -Oil consumption: 30 % (by different energy saving measures) -NOx: 93 % (through optimisation of the engine and catalytic converters) -HC: 88 % (by catalytic converters) -CO: 81 % (by catalytic converters) -Particles: 35 % The sulphur content in the fuel was assumed to be 0,09 %. Emissions of SO2 were calculated from the fuel consumption using the sulphur content in the fuel. Emissions of CO2 were calculated from the fuel consumption using the carbon content in the fuel.
Literature Reference	Energi- och emissionsuppgifter för godstransporter i Sverige, Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning 1997, NGM- Nätverket för Godstransporter och Miljön.
Notes	The energy use and emissions from ferries vary greatly. The result depend on calculation method, size of the ship, speed, route, age of the ship, fuel etc. Swedish Shipowners Assossiation are working on an updated and more detailed version of emission data from ferries.

SPINE LCI dataset: Fertilizing in silviculture

Administrative	
Finished	Y
Date Completed	1994-02-24
Copyright	Open
Availability	Open

Technical System	
Name	Fertilizing in silviculture
Functional Unit	ha
Functional Unit Explanation	Per ha fertilized forest land.
Process Type	Gate to gate
Site	Sweden
Sector	Forestry
Owner	Sweden

Technical system description	Fertilizing is in industrial silviculture made 1 -3 times. This step describes one fertilization. The reason is to increase the growth rate during some years. The spreading is performed with tractor (14%) and helicopter (86%). Assumed is that SKOG-CAN 27,2 % N is used (presented as N-fertilizer).

System Boundaries	
Nature Boundary	Emissions from combustion of fuels are not included.
Time Boundary	The data collected are representative for the time period 1992-1994.
Geographical Boundary	Sweden
Other Boundaries	Production and distribution of fertilizer is not included.
Allocations	N/A
Systems Expansions	N/A

Flow Data	
General Activity QMetaData	
Date Conceived	1994-02-24
Data Type	Unspecified, expert outspoke
Represents	
Method	Personal communication with U. Hallonborg. Further information is available for each specific flow.
Literature Reference	U. Hallonborg, Skogforsk
Notes	The energy use and emissions from ferries vary greatly. The result depend on calculation method, size of the ship, speed, route, age of the ship, fuel etc. Swedish Shipowners Assossiation are working on an updated and more detailed version of emission data from ferries.

	--
Intended User	LCA practioners
General Purpose	The purpose is to supply with LCA-data for forestry to be used in further studies of wood products.
Detailed Purpose	These data are an update of earlier data on the same subject. Can also be used as an average for Sweden.
Commissioner	- Stora Corporate Research, Box 601 661 29 Säffle Sweden.
Practitioner	Swan, Göran - Stora Corporate Research, Box 601, S-661 29 Säffle, Sweden.
Reviewer	
Applicability	These data are valid for large scale nursery in forestry. It is important to check the type of fuel used. In this case, fossil fuel is assumed to be used. Other data is available from other forest companies, or from Skogforsk, or STFI. The silviculture process in Sweden has eight steps: 1. Plant nursing 2. Soil preparation 3. Planting 4. Clearing 5. Thinning 6. Fertilizing 7. Final felling 8. Forwarding This is the first step. Different forest owners use the two spreading methods to different extents.

Availability	Public

Technical System	
Name	Final felling
Functional Unit	ha
Functional Unit Explanation	Per hectare forest that is being finally felled.
Process Type	Gate to gate
Site	Middle Sweden
Sector	Forestry
Owner	Middle Sweden
Technical system description	Final felling is the final activity in siviculture before the forest area is reforestated. Sometimes a shield of old trees are left for two reasons: 1) Climal protection for young tree plants. 2) Seeding puposes. 3) Added value of the old trees. In this case all wood is assumed to be taken at the same time.

System Boundaries	
Nature Boundary	Emissions caused by combustion of fuels is not included.
Time Boundary	The data collected are representative for the time period 1992-1994.
Geographical Boundary	Central Sweden

About Inventory

Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow.

	When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998

SPINE LCI dataset: Flame laminate treatment of textiles

Administrative	
Finished	Y
Date Completed	1997-03-01
Copyright	
Availability	Public

Technical System	
Name	Flame laminate treatment of textiles
Functional Unit	m2
Functional Unit Explanation	1 m2 flame laminated textile
Process Type	Gate to gate

Site	Texla Industri AB Trankärrsgatan 13 425 37 Hisings-kärra Sweden
Sector	Materials and components
Owner	Texla Industri AB Trankärrsgatan 13 425 37 Hisings-kärra Sweden
Technical system description	Melting of polyuretan foam, under open flame, and attaching it to textiles.

System Boundaries

Nature Boundary	The company is not obligated to state other emission- or waste substances than the Swedish Environmental Protection law requires. The raw materials, such as textiles, used in the production is not mentioned.
Time Boundary	The company is obligated to write an Environmental report once every year. Though the legislated limits can be changed only if the activity is changed.
Geographical Boundary	Sweden
Other Boundaries	
Allocations	
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1996
Data Type	Unspecified
Represents	
Method	Study Environmental Report. The data in the table has been converted into amounts per functional unit. The data from the environmental report has therefore been devided by the annual production for 1996, which was 2460000 m3 laminated textiles.
Literature Reference	Environmental report from Texla Industri AB for 1996, The Environmental Administration in the municipality of Göteborg.
Notes	The data type unspecified implies that one does not know the origin of the data. The material, which is treated in the laminate process, is not mentioned as input in the flow table. The method is specified for the emissions.

About Inventory

Publication	Environmental report from Texla Industri AB for 1996, The Environmental Administration in the municipality of Göteborg. -- Data documented by: Maria Erixson and Sara Ågren, project employed for the database projet at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	To show the environmental load
General Purpose	The purpose of the Environmental report is to be the base for permission trial of activities that is harmful to the environment and further to make shore that the company comply with the decision.
Detailed Purpose	To control that the legislated limits are not exceeded.
Commissioner	- Swedish government via The Board of County in Göteborg and Bohus or The Environmental Administration in the municipality of Göteborg. .
Practitioner	Bengtsson, Bengt - Texla Industri AB Trankärrsgatan 13 425 37 Hisings-kärra Sweden.
Reviewer	- Swedish government via The Board of County in Göteborg and Bohus or The Environmental Administration in the municipality of Göteborg.
Applicability	The function of the system is not very well described, contact the company for more information. The raw materials, such as textiles, used in the production is not mentioned.
About Data	No margin of error is found in the report, and one can assume that a lot of values have been rounded. The values often end with zeroes and occasionally are indicated to be an approximation.
Notes	

SPINE LCI dataset: Flame retardant polyester (Trevira CS) covering of sofa. ESA-DBP

Administrative

Finished	Y
Date Completed	2004
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System

Name	Flame retardant polyester (Trevira CS) covering of sofa. ESA-DBP
Functional Unit	''The functional unit was: surface covering of a 3-seat sofa for private use during 10 years.'' For Trevira CS fabric it is 3.56 kg per sofa.
Functional Unit Explanation	See 'Function'.
Process Type	Cradle to grave
Site	Not applicable

Sector	Consumer goods
Owner	Not applicable
Technical system description	The system is descibed in ''Dahllöf L, 2004, Methodological issues in the LCA procedure for the textile sector - a case study concerning fabrics for a sofa. Environmental Systems Analysis report 2004:7, Chalmers University of Technology, Gothenburg, Sweden'': http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2004--7.pdf Other processes in the CPM Database also included in the above publication: 'Cotton (conventional) fibres production. ESA-DBP', 'Cotton covering of sofa. ESA-DBP ' and 'Wool/polyamide covering of sofa. ESA-DBP'. ''The function was to provide a surface covering for a sofa. The color of the fabric was red. Six laundry washings for the Trevira CS fabric were assumed in order to see the relative environmental importance of the cleaning step. It was assumed that the fabric could be readily removed from the sofa. Incineration at disposal of the fabric used was assumed in the base case (the most probable life cycle chains). Heat recovery and emissions from the incineration were taken into account, but possible oil saving or replacement of other waste in the incinerator was only tested in the sensitivity analysis.'' ''Trevira CS is a flame retardant fiber. The flame retardance is obtained through co-polymerization of the monomers with O-Phospholane (Neckelmann 2001). In figure 3 (in the above publication) the different companies and their role in the production of Trevira CS fabric are shown. The monomers are terephtalic acid and ethylene glycol. The catalyst is antimony trioxide (possibly carcinogenic to humans (Ellebäk Laursen et al 1997)). This polymerisation is, for instance, done by the Trevira group in their factory in Guben, Germany. The Trevira group also has a factory in Portugal. The spun yarn was assumed to be only filament yarn. For fabrics used on sofas, filament yarn is the main type in the case of Trevira CS.'' In the litterature reference following processes are included: - Production of Trevira CS filament yarn - Truck from production site of Trevira CS yarn to texturing and dyeing site - Texturing - Dyeing of the yarn - Truck and freighter from yarn texturer and dyer to Swedish weaving mill - Weaving without sizing in Sweden - Business trips from Trevira CS weaving mills site - Truck from weaving mill to wet treatment plant - Thermofix (the fabric is fixated with vapor) - Truck from Swedish wet treatment plant back to weaving mill - Textile distribution at weaving mill in Sweden - Truck from Swedish weaving mill to upholstery plant - Upholstering of Trevira CS fabric on a 3-seat sofa - Laundry of Trevira CS fabric - Truck from user to incineration plant - Incineration of Trevira CS fabric

System Boundaries

Nature Boundary	''Mineral resources and water were traced back to their reserves in nature and emissions were followed to air, water or soil. Below are the exceptions found, when the processes were not traced back to the nature reserves or water, or followed to air, water or ground. - A wastewater-treatment plant was included, but the decomposition of each individual chemical was not studied. - The production of the process chemicals and some packaging materials were not within the system boundaries.''
Time Boundary	''Data were collected by interviews from 1999 to 2002, but data from reports ranged from 1993 to 1998. Most reports were from 1997.''
Geographical Boundary	''Trevira CS: *production of Trevira CS polymer fibers: Germany *production of Trevira CS filament yarn and dyeing of the fibers: Denmark *weaving, finishing, upholstering, use and incineration: Sweden''
Other Boundaries	''The fabrics were assumed to not to be worn out before they were disposed of, a realistic scenario for Swedish conditions. Therefore the abrasion resistance was not taken into consideration in the study, while the effect of different lifetimes of the fabrics is discussed in chapter 4.3.7.'' ''Production of Trevira CS filament yarn The plant has its own wastewater-treatment. The COD reported was assumed to be measured after the wastewater-treatment, therefore the water is assumed to go to water and not the technosphere. The yarn is wound onto a spool. 20-30 kilos are on one spool and the spools are reused (or sent for recycling), therefore they are not reported. General energy use was not reported. The travel at work is not known, but is probably insignificant. - Data source: average production data in Europe. The data are a weighted average based on production volumes of 7 different plants in Germany, Austria and the Netherlands (about 30% of total European production). Probably no general energy or water consumption was

	included. In this LCA study for fabrics, discharges to water were assumed to end up in water. - Data includes production of the yarn. There are several types of yarn manufacturing, and filament or staple yarn is the product.'' ''Texturing The cardboard rolls were assumed to be reused many times, and they were therefore left out. 20-30 kg yarn is wound onto a spool.'' ''Truck and freighter from yarn texturer and dyer to Swedish weaving mill The distance by boat was assumed to 40 km and by truck to 300 km. The freighter was assumed to medium size (2000-8000 dead weight tons), Load factor: 60%.'' ''Business trips from Trevira CS weaving mills site The travel distance was calculated to 0.93 vkm/kg fabric.'' ''Truck from weaving mill to wet treatment plant The distance was assumed to 30 km.'' ''Thermofix (the fabric is fixated with vapor) - Data were estimated from one wet treatment plant, and literature values for a comparison are found below. The plant uses light fuel oil and water to generate steam. Unfortunately, only total water and energy use was known and the plant has many different activities. The calculation based on weight gave the value 23 MJ for use of light fuel oil, which is much higher than the literature data. Another plant uses LPG, but that plant had no data about gas and water consumption. One plant uses industrial water and the other uses water from a well. - According to Ellebäk Laursen et al (1997) finishing (a process where properties of the fabric are changed, often with chemicals) uses 4.05-8.00 MJ/kg fabrics. Dyeing, washing and drying uses 3.40-13.2 MJ/kg. Therefore, the estimated 8 MJ/kg seems realistic. The water consumption in the inventory was estimated from the plant. - Amount of cardboard is for the rolls and comes from one wet treatment mill.'' ''Truck from Swedish wet treatment plant back to weaving mill The distance was assumed to 30 km.'' ''Truck from Swedish weaving mill to upholstery plant The distance was assumed to 500 km.'' ''Laundry of Trevira CS fabric The difference as compared laundering of cotton is that the load factor in the washing machine was assumed to 2/3 according to instructions from Electrolux (1996). Tumble-drying was assumed to be one third of the time for cotton tumble-drying.'' ''Truck from user to incineration plant The distance to the incineration plant was assumed to 25 km.''
Allocations	''The allocation procedure by mass was not uniform in applications. The deviations were as follows: - No flows were allocated to waste, such as edge strips from weaving or cardboard or textile samples. - In the weaving operation, allocation was made per meter fabric. - Allocations for light fuel oil, heavy fuel oil, LPG and natural gas production were not known as well as for electricity from natural gas or oil and production of sodium hydroxide and ethylene glycol used for the sensitivity analysis. - For electricity production (Swedish average) the allocation between recycling and virgin materials was according to the 50/50 method. When heat was also produced, the allocation was according to energy output. - For electricity (European average), exergy values were used to allocate between electricity and heat.''
Systems Expansions	Not applicable.

About Inventory	
Publication	Dahllöf L, 2004, Methodological issues in the LCA procedure for the textile sector - a case study concerning fabrics for a sofa. Environmental Systems Analysis report 2004:7, Chalmers University of Technology, Gothenburg, Sweden http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2004-7.pdf
Intended User	LCA and textile practitioner
General Purpose	Part of doctoral studies. ''The overall purpose of the studies is to give suggestions for solving some of the methodological issues within the LCA method when used in the field of textiles.''
Detailed Purpose	''The goal of this case study was to identify, map and discuss LCA methodological issues in the textile sector. This was done by carrying out an LCA study with the goal of ranking three fabric types for a sofa. i) The main reason for carrying out the study was that the LCA methodology is not fully developed and different sectors have different method development needs. This work was being done on the basis of interest from the textile industry in Sweden. ii) The study could be used for further development regarding methodological issues in the efforts to establish Product Specific Rules (PSRs) for Certified Environmental Declarations (EPDs) in the textile sector (the Swedish Environmental Management Council 2000) and for the modification work of the ISO 14040 (1997) - ISO 14043 (2000) standards. iii) It is intended to be used by purchasers, designers, etc., in the textile industry as well as for researchers and others working with the ISO 14040 (1997) - ISO 14043 (2000) standards.''

Reviewer	Maria Walenius Henriksson - IFP Research AB
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above.
About Data	ESA Database Project. Years: 2009-2011. Administering organisation: Chalmers University of Technology, the department of Environmental Systems Analysis. Financier: The Swedish Research Council. Importer of data: Filippa Fuhrman (ESA), assisted by Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	The original publication includes more information about data. ''The studies are being carried out at the Environmental Systems Analysis Department at Chalmers University of Technology in Gothenburg, Sweden and are being financed mainly by Stiftelsen Svensk Textilforskning and CPM, Centre for Environmental Assessment of Product and Material Systems.''

SPINE LCI dataset: Flexible PUR foam

Administrative	
Finished	Y
Date Completed	1996
Copyright	
Availability	

Technical System

Name	Flexible PUR foam
Functional Unit	1 kg of flexible PUR foam
Functional Unit Explanation	
Process Type	Gate to gate
Site	
Sector	Materials and components
Owner	
Technical system description	This set of data does not concern the production of the polyurethane precursors (TDI, MDI, Polyols) but the production of one particular type of polyurethane foam. In fact, polyurethane foam can be rigid, flexible, etc. and then one can find different recipies for it (different mixing of the precursors). In fact, here is the recipe of the FLEXIBLE POLYURETHANE FOAM.

SPINE LCI dataset: Floor maintenance. ESA-DBP

Administrative	
Finished	Y
Date Completed	1999
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public.

Technical System	
Name	Floor maintenance. ESA-DBP
Functional Unit	1 m2 * year
Functional Unit Explanation	Excerpt from the report (see 'Publication'): ''For the LCI one square meter, one year and once a week were the parameters used to evaluate the linoleum maintenance impact.''
Process Type	Gate to gate
Site	Not applicable
Sector	Activities of households as employers
Owner	Not applicable
Technical system description	Floor maintenance is assumed to be done manually with a mop and the swedish cleaning product ''All rent''. This process is included in the system described in: Blanco-Rosete S. R., 2002, LCA data structure and time series related to construction and maintenance in Sweden. Environmental Systems Analysis report 2002:14, Chalmers University of Technology, Gothenburg, Sweden Other processes in the CPM Database also included in the above publication: Swedish red paint manufacturing and application. ESA-DBP Clay roof tile manufacturing. ESA-DBP Exterior coating (Swedish red paint) maintenance. ESA-DBP Pine window production. ESA-DBP

About Inventory

Publication	Blanco-Rosete S. R., 2002, LCA data structure and time series related to construction and maintenance in Sweden. Environmental Systems Analysis report 2002:14, Chalmers University of Technology, Gothenburg, Sweden
Intended User	LCA practitioners.
General Purpose	This process data set is recalculated to fit in the Master Thesis given in 'Publication'. Excerpt from the report (see 'Publication'): ''Construction, building maintenance and housing management contribute to a large extent to the environmental impact. When housing owners and managers perform their activities they should be aware of the environmental effects they cause. The environmental impact of existing houses could be addressed and diminished within the possibilities of a clever management.''
Detailed Purpose	Excerpt from the report (see 'Publication'): ''This master thesis descibes and defines a building system model for a multi-family house in Gothenburg over a 30 year period from 1970 to 2002 . The model was used to collect environmental impact information regarding materials or products used in the construction and maintenance of a building . The environmental impact ofa a multi-family house was evaluated through a Life Cycle Assessment (LCA). Finally to account the long sevice lifetime of a multi-family house two case studies were carried out to test if the use of Time series can illustrate the environmental impact of maintenance activities caused by decisionmaking in housing management.''
Commissioner	Not applicable - .
Practitioner	Sergio R. Blanco-Rosete - .
Reviewer	Birgit Brunklaus - Environmental Systems Analysis
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries'.
About Data	Excerpt from the report (see 'Publication'): ''Data for the maintenance of linoleum is taken from one of the described scenarios in ''Life cycle assessment for building products. The significance of the usage phase.'' (Paulsen ,1999). In that study tables for emissions are presented as factors in order to estimate the impact produced according to the area, time and frequency the maintenance is taking place.'' ESA Database Project. Years: 2009-2011. Documentation completed for this data set: 2010-09-21 Administering organisation: Chalmers University of Technology, the division of Environmental Systems Analysis. Financier: The Swedish Research Council. Documentor of data: Filippa Fuhrman (ESA). Review committee for documented data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).

SPINE LCI dataset: Forging of ingot into steel bars, 350 mm

Administrative

Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Forging of ingot into steel bars, 350 mm
Functional Unit	One ton of forged steel bars, 350 mm
Functional Unit Explanation	The forged steel bars will serve as raw material for the ring production at the ring mill at Ovako Steel AB in Hofors. The rings will later be processed into bearing rings at SKFs site in Göteborg and finally mounted into the SKF spherical roller bearing 232/530.
Process Type	Gate to gate
Site	Scana Steel Söderfors ABBox 104 815 04 SÖDERFORS
Sector	Materials and components
Owner	Scana Steel Söderfors ABBox 104 815 04 SÖDERFORS
Technical system description	This activity is a process step in the system ''Production of bearing rings'', this activity is available in the SPINE@CPM database. When producing the bearing rings the heated steel ingot needs to be forged into steel bars. This dataset represents environmental impact from this activity. The ingot is cold when the process starts at the forge at Scana Steel AB in Söderfors. As a first step the ingot is heated in an oven. The first part of the oven heats the ingot from room temperature to 180°C immediately. The ingot is then transported through different temperature areas and is slowly heated until it reaches 1150°C. This heating process takes approximately 1-2 days. The next process step is pressing in the forging press. The heated ingot is put in the press and edged into round shape. Finally the now nearly round bars are pressed complete round while rotating against a round swage in form of two half circles. The forging is completed and the forged bars are inspected and cooled in room temperature for approximately one day.

System Boundaries	
Nature Boundary	Emissions to water are not known. Emissions to air are included. The emissions to air refer mostly to the combustion of the heavy fuel oil, taking place in the forge oven.
Time Boundary	All data refers to year 2001. No changes are planned for the nearest future.
Geographical Boundary	The forging mill is located at Scana Steel Söderfors AB in Söderfors, Sweden.
Other Boundaries	No internal transport is included. The production of heavy fuel oil and electricity is NOT included in this dataset, but must be followed from the grave to obtain the total environmental impact.
Allocations	Allocation have been made according to weight.
Systems Expansions	Not applicable

Flow Data	
General Activity QMetaData	
Date Conceived	02-08-01 - 02-12-31
Data Type	Derived, mixed
Represents	See 'Function'.
Method	The data has been gathered from interviews with Leif Hedström at Scana Steel Söderfors AB in Söderfors. He picked data from Scana´s environmental report from year 2001. Some data has been estimated by Leif Hedström. According to Leif, 15017 ton forged material was produced during year 2001. This is approximately 2/3 of all material totally produced at Scana Steel AB in Söderfors 2001. 2/3 of the emissions and the electricity and oil consumption in the environmental report for year 2001, was allocated to the forged material. Consumption of grease and lubricating oil is allocated to the forged material 100%, according to Leif Hedström.

About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Data reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The dataset is applicable to the forging of ingot into steelbars, 350 mm, at the forging mill at Scana Steel Söderfors AB in Söderfors, Sweden.
About Data	Data is gathered from interviews with Leif Heström at Scana Steel Söderfors AB in Söderfors, Sweden. The data is obtained from Scana Steel´s environmental report 2001.

SPINE LCI dataset: Forwarding of harvested wood

Administrative

Finished	Y

Date Completed	1998-02-13
Copyright	None
Availability	Public

Technical System

Name	Forwarding of harvested wood
Functional Unit	m3sub
Functional Unit Explanation	Per m3sub softwood transported from the felling site to the roadside.
Process Type	Gate to gate
Site	Middle Sweden
Sector	Forestry
Owner	Middle Sweden
Technical system description	Forwarding is the transport of any felled wood (from thinning or final felling) from the felling area to the road side. This activity is succeded by a transport of the wood to a sawmill or a pulp mill. These transports vary from case to case and are therfore not included in this line of operations.

System Boundaries

Nature Boundary	Emissions caused by combustion of fuels is not included.
Time Boundary	The data collected are representative for the time period 1992-1994.
Geographical Boundary	Central Sweden
Other Boundaries	N/A
Allocations	N/A

About Inventory	
Publication	Nne -- Data documented by: Göran Swan, Ola Svending, STORA Corporate Research Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	LCA practitioners
General Purpose	The purpose is to supply with LCA-data for forestry to be used in further studies of wood products.
Detailed Purpose	These data are an update of earlier data on the same subject. To be used in LCA representing the forwarding part of forestry in central Sweden. Can also be used as an average for Sweden.
Commissioner	- Stora Corporate Research, Box 601 661 29 Säffle Sweden.
Practitioner	Swan, Göran - Stora Corporate Research, Box 601, S-661 29 Säffle, Sweden.
Reviewer	
Applicability	These data are valid for large scale forwarding in forestry. It is important to check the type of fuel used. In this case, fossil fuel is assumed to be used. Other data is available from other forest companies, or from Skogforsk, or STFI. The silviculture process in Sweden has eight steps: 1. Plant nursing 2. Soil preparation 3. Planting 4. Clearing 5. Thinning 6. Fertilizing 7. Final felling 8. Forwarding This is the eighth step.

SPINE LCI dataset: Fossil diesel - EN590 combustion in heavy duty truck or bus, Euro V, tank-to-wheel, f3 fuels

Administrative	
Finished	Y
Date Completed	2013-11-30
Copyright	f3 - Swedish Knowledge Centre for Renewable Transportation Fuels
Availability	Public

Technical System	
Name	Fossil diesel - EN590 combustion in heavy duty truck or bus, Euro V, tank-to-wheel, f3 fuels
Functional Unit	1 MJ
Functional Unit Explanation	1 MJ input of fossil diesel EN590 to vehicle tank

Process Type	Gate to grave
Site	
Sector	Fuel
Owner	
Technical system description	The data represent emissions from fossil diesel - EN590 combustion in heavy duty truck or bus, Euro V, tank-to-wheel. The emission legislation uses the definition of a heavy duty vehicle having a gross weight of 3.5 tons or more. The reported emission factors should be considered as generic data, and it should be noted that the emissions for a specific vehicle and a specific mission might differ from those generic data. For example, the limit values for certification of engines have been used as basis for deriving some of the emission factors. The duty cycles used for certification are defined to cover the whole range of typical loads of an engine in different operations. The operation of a specific vehicle can however differ from the duty cycle used in the certification, resulting in different emissions than calculated with the generic emission factors. E.g. for the regulated emissions: nitrous oxides, particles, total organic compounds and carbon monoxide, the values are conservative based on the maximum emissions limits per kWh of engine output when driving at the best point (the optimal engine speed/torque operating point). In reality, the values are often lower.

Method	The emission factors (EF, kg/MJ) for the regulated emissions have been estimated based on ETC (transient test cycle for truck and bus engines), legislation limits for Euro V (2005/55/EC). The ETC cycle is for heavy duty engines and vehicle (www.dieselnet.com). Equation for calculation of emission factors for fuel use: Efficiency: 0.44 (?)= (energy work/energy in fuel) which is the efficiency at the best point (the optimal engine speed/torque operating point) and which gives the maximum emission factors within the legislation limit. EF fuel use (g/MJ)=EF work (g/kWh)/3.6*? Emissions of CO2 and SO2 have been calculated based on carbon- and sulphur content in the fuel, see documentation "Data compilation method for a specific flow" and "Reference" in the Flow table. Emissions of CH4 was calculated from JRC (2013) and N2O was best estimate.
Literature Reference	Main references: (1) 2005/55/EC (2) www.dieselnet.com (3) JRC (2013) Tank-to-wheels, Report Version 4.0, JEC well -to-wheels analysis, well-to-wheels analysis of future automotive fuels and and powertrains in the European context, July 2013 (4) SPBI (http://spbi.se/blog/faktadatabas/artiklar/berakningsmodeller/) (5) Dir 2009/30/EC

Functional Unit	1 MJ
Functional Unit Explanation	1 MJ input of fossil diesel EN590 to vehicle tank
Process Type	Gate to grave
Site	
Sector	Fuel
Owner	
Technical system description	The data represent emissions fromfossil fuel - EN590 combustion in heavy duty truck or bus, Euro VI, tank-to-wheel. The emission legislation uses the definition of a heavy duty vehicle having a gross weight of 3.5 tons or more. The reported emission factors should be considered as generic data, and it should be noted that the emissions for a specific vehicle and a specific mission might differ from those generic data. For example, the limit values for certification of engines have been used as basis for deriving some of the emission factors. The duty cycles used for certification are defined to cover the whole range of typical loads of an engine in different operations. The operation of a specific vehicle can however differ from the duty cycle used in the certification, resulting in different emissions than calculated with the generic emission factors. E.g. for the regulated emissions: nitrous oxides, particles, total organic compounds and carbon monoxide, the values are conservative based on the maximum emissions limits per kWh of engine output when driving at the best point (the optimal engine speed/torque operating point). In reality, the values are often lower.

SPINE LCI dataset: France, electricity generation mix 1998

Administrative	
Finished	Y
Date Completed	2001-01-31
Copyright	IEA
Availability	Public

Technical System	
Name	France, electricity generation mix 1998
Functional Unit	Total electricity produced during 1998
Functional Unit Explanation	The electricity mix refer to the total amount of electricity generated by different power sources expressed in GWh during the year 1998.
Process Type	Unit operation
Site	France
Sector	Energyware
Owner	France
Technical system description	The generation of electricity with different power generating systems in France during the year 1998. France includes Monaco, and excludes overseas departments (Matinique, Guadeloupe, French Polynesia and Réunion).

System Boundaries	
Nature Boundary	Not applicable, since the data only refer to the electricity generation mix. The environmental load for generation of electricity is not included.
Time Boundary	The data refer to 1998.
Geographical Boundary	Only electricity produced in Australia is considered. Import or export of electricity is not included.
Other Boundaries	-
Allocations	Not applicable
Systems Expansions	Not applicable

About Inventory

Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version

	- Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998
About Data	
Notes	

SPINE LCI dataset: Freight plane, MD-82

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Freight plane, MD-82
Functional Unit	1 tonkm, 300 km, 65%
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 km calculated for 300 km flight distance and an average utilisation level equivalent to 65 % passenger occupation (9 450 kg)
Process Type	Unit operation
Site	Sweden

Sector	Air transport
Owner	Sweden
Technical system description	Operation of MD-82 aircraft, only carrying cargo. The operation includes take-off, climb, cruise, descent and landing (including operations on the ground). *Technical data for the aircraft:* Maximum take-off weight 67,8 tonnes. Maximum payload (i.e. maximum loading capacity with regard to weight) 17100 tonnes. Max cruising altitude 11,300 metres Cruising speed 815-825 km/h Length: 45.1 m Wing span: 32.9 m Range: 3,200 km Engine: P&W JT8D-217C/-219

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents aircraft in use in 1997
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The data is only valid for a flight distance of 300 km, and an average utilisation equivalent to 65 % passenger occupation (9 450 kg). The maximum value is equivalent to 49 % (6 450 kg) and the minimum value is equivalent to 86 % passenger occupation (12 450 kg). *Parameters not considered* -External conditions i.e. climate etc -Maintenance level of the aircraft. *Excluded subsystems* -Precombustion, i.e. production and distribution of the fuel -Maintenance of the aircraft -After-treatment of the aircraft -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Modeled data
Represents	See 'Function'.
Method	The energy use and emissions per tonkm was obtained by simulation calculations performed by FFA (The Aeronautical Research Institute of Sweden) for a flight distance of 300 km. The *quantity value* is equivalent to a passenger occupation of 65% (9450 kg), the *minimum value* corresponds to a passenger occupation of 81 % (12450 kg) and the *maximum value* of 49 % (6450 kg). The simulation calculations is performed in two steps. To obtain the fuel consumption, the flight path for each section is simulated, where both load and flight distance is accounted for. The position of the aircraft and the operation conditions of the engine are established for every second of the flight. This data is used in a new simulation where the exhaust emissions are calculated with regard to engine speed and flying altitude for every moment of the flight. The result from the simulation is then used to calculate the energy use and emissions per tonkm. The data include landing and take off, i.e. flight operations below 3000 feet (including operation of the ground) *Data used for the fuel:* -Thermal value: 43,2 MJ/kg -Sulphur content: 500 ppm
Literature Reference	Larsson, Lars Gunnar, Calculations performed at FFA for NGM, 1997, Not published
Notes	The data is only valid for a flight distance of 300 km The energy use and emissions vary substantially during the different phases of the flight. A flight may be considered to consist of 5 phases - take-off, climb, cruise, descent and landing (including operations on the ground). The take-off and climb are the most energy demanding phases and give rise to extensive emissions. For flights over 300 km, the energy use and emissions at take-off, climb, descent and landing may be considered to be constant, independent of the flight distance.

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Larson, Lars-Gunnar - FFA (Flygtekniska försöksanstalten), Box 11021 S-161 11 Bromma Sweden.
Reviewer	
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the plane, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. Goods transportation by air transport is done either in special freight planes or in regular passenger flights together with passengers. Air transport is primarily used for transportation of valuable or fragile goods and for speedy deliveries. Air transport is also more expensive than other modes of transportation. Consequently, very little goods are transported by aircraft. The major part of the goods is transported in regular passenger planes. The amount of goods that can be carried in passenger aircraft is however small. The average load of goods in a passenger aircraft is below 100 kg and is equivalent to an average passenger with average luggage. The passenger occupation will therefore have a large influence on the energy use and the emissions for goods carried in regular passenger aircraft. The MD-82 was chosen to represent Swedish air transport since it is one of the most common used aircraft in domestic regular traffic in Sweden. The aircraft represents an average regarding both technical standard and emissions. The aircraft has a long average lifetime. ***Utilisation level and distance*** For air transports, data on energy use and emissions per tonkm may only be given for a specific flight distance since the energy use and emissions vary substantially during the

	different phases of the flight. A flight may be considered to consist of 5 phases - take-off, climb, cruise, descent and landing (including operations on the ground). The take-off and climb are the most energy demanding phases and give rise to extensive emissions. For flights longer than 300 km, the energy use and emissions at take-off, climb, descent and landing may be considered to be constant, independent of the flight distance. Consequently, the longer the flight the more energy efficient transport. Aircraft are optimised for energy efficiency during the cruise phase. The average distance for Swedish domestic flights is between 300 and 600 km. Data for freight planes was therefore both given for a flight distance of 300 km and 600 km. The average utilisation was assumed to be equivalent to a passenger occupation of 65 %, which may be a conservative assumption compared to actual operation. To obtain a minimum and a maximum value for the energy use and emissions, data was also given for a higher utilisation (81 %, the minimum value in the data) and a lower utilisation (49 %, the maximum value). To calculate energy use and emissions for other flight distances, the following relations may be used, where x=total distance in km. These relations are valid for flights longer than 300 km and concern a MD-82 loaded with 9450 kg i.e. a utilisation level equivalent to a passenger occupation of 65%. -Kerosene: 2220 + 3,1*(x-300) [kg] -CO2: 7015 + 9,8*(x-300) [kg] -CO: 9,6 + 0,0129*(x-300) [kg] -HC: 1,848 + 0,0049*(x-300) [kg] -NOx: 29,85 + 0,031*(x-300) [kg] -SO2: 2,22 + 0,003*(x-300) [kg]
About Data	The data is based on simulation calculations performed at FFA (The Aeronautical Research Institute of Sweden).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

More detailed information is then needed e.g. regarding the plane, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. Air transport is done either in special freight planes or in regular passenger flights together with passengers. Air transport is primarily used for transportation of valuable or fragile goods and for speedy deliveries and is also more expensive than other modes of transportation. Consequently, very little goods are transported by aircraft. The share of goods transported by special freight planes is low compared to the goods transported on regular passenger flights. The amount of goods that can be carried in passenger aircraft is however small. The average load of goods in a passenger aircraft is below 100 kg and is equivalent to an average passenger with average luggage. The passenger occupation will therefore have a large influence on the energy use and the emissions for goods carried in regular passenger aircraft. The MD-82 was chosen to represent Swedish air transport since it is one of the most common used aircraft in domestic regular traffic in Sweden. The aircraft represents an average regarding both technical standard and emissions. The aircraft has a long average lifetime.

	Utilisation level and distance For air transports, data on energy use and emissions per tonkm may only be given for a specific flight distance since the energy use and emissions vary substantially during the different phases of the flight. A flight may be considered to consist of 5 phases - take-off, climb, cruise, descent and landing (including operations on the ground). The take-off and climb are the most energy demanding phases and give rise to extensive emissions. For flights over 300 km, the energy use and emissions at take-off, climb, descent and landing may be considered to be constant, independent of the flight distance. Consequently, the longer the flight the more energy efficient transport. Aircraft are optimised for energy efficiency during the cruise phase. The average distance for Swedish domestic flights is 300 - 600 km. Data for freight planes was therefore given for a flight distance of 300 km and 600 km. The average utilisation level was assumed to be 65 %, which may be a conservative assumption compared to actual operation. To obtain a minimum and a maximum value for the energy use and emissions, data is also given for a higher utilisation (81 %, the minimum value in the data) and a lower utilisation (49 %, the maximum value). Data for passenger planes was only given for a short flight distance (300 km) and a low average utilisation level (49 %) and a long flight distance (600 km) and a high average utilisation level (81%). The reason for this was to give an indication of a maximum and a minimum value of the energy use and emissions for goods carried in passenger planes in Swedish domestic traffic. To calculate energy use and emissions for other flight distances, the following relations may be used, where x=total distance in km. Kerosene: 2220 + 3,1*(x-300) [kg] CO2: 7015 + 9,8*(x-300) [kg] CO: 9,6 + 0,0129*(x-300) [kg] HC: 1,848 + 0,0049*(x-300) [kg] NOx: 29,85 + 0,031*(x-300) [kg] SO2: 2,22 + 0,003*(x-300) [kg] These relations are valid for flights longer than 300 km and concern a MD-82 loaded with 9450 kg i.e. a utilisation level equivalent to a passenger occupation of 65%.
About Data	The data is based on simulation calculations performed at FFA (Flygtekniska försöksanstalten).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. SPINE LCI dataset: Freighter, 2000-8000 dwt

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System

Name	Freighter, 2000-8000 dwt
Functional Unit	1 tonkm, 50-60 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 50 % for tankers and 60% for other freighters. An utilisation level of 50 % for tankers and 60% for other freighters is representative for Swedish domestic traffic if *empty trips are included.*
Process Type	Unit operation
Site	Sweden
Sector	Sea transport
Owner	Sweden
Technical system description	Operation i.e. propulsion of Swedish flagged freighters between 2000 and 8000 dwt (deadweight tonnes), which are members of the Swedish Shipowners´ Association. Freighters include all vessels except RoRo vessels and ferries. Freighters thus include a large variety of different vessels; tankers, container ships, LoLo vessels, bulk vessels, vessels built for a special route etc.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO_2 -tax regulated CO_2. Diffuse emissions to air, emissions to water (e.g. discharges of oil) and emissions to ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents the fleet in 1997
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 50 % for tankers and 60% for other freighters 60% (including empty trips) *Parameters not considered* -Driving technique -External conditions e.g. climate etc. -Maintenance level of the vessel *Excluded subsystems* -Precombustion, i.e. production and distribution of the fuel. -Maintenance of the vessel (e.g. use of anti fouling) -After-treatment of the vessel -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data	
General Activity QMetaData	
Date Conceived	1990-01-01 - 1997-01-01
Data Type	Derived, unspecified
Represents	See 'Function'.
Method	The basis for the data are all Swedish flagged freighters between 2000 and 8000 deadweight tonnes, which are members of the Swedish Shipowners' Association. The *quantity value* for all parameters is an average of all vessels in the population. The *minimum value* corresponds to the individual with the lowest energy use and emissions in the population, and the *maximum value* to the individual with the largest energy use and emissions in the population. The *utilisation level* with regard to weight is 50 % for tankers and 60 % for other freighters, based on Demker et al. The energy use and emissions per tonkm for each vessel was calculated (see Specific QMetaData for each flow). For each vessel, the loading capacity was stated in deadweight tonnes (Skeppsregister 1995), installed engine power in kW (Skeppsregister 1995) and speed in knots (Lloyds list). The share of two-stroke and four-stroke engines in each vessel was determined by the size of the vessel according to Alexandersson. All vessels in the population were then used to calculate an average value.
Literature Reference	Alexandersson, A., *Sjöfartens utsläpp av avgaser*, MariTerm, TFB-rapport 1991:18 Demker, G. et al. *Miljöeffekter av transportmedelsval för godstransporter*, MariTerm, KFB-rapport, 1994:6 *Skeppsregister 1995*, Swedish Shipowner Association Sjöbris, A., Flodström, E. *Emissions och energivärderingsprinciper för transportsystem*, MariTerm, KFB-rapport

	1994:9 *Lloyds list*, 1996
Notes	The data is only valid for a flight distance of 600 km The energy use and emissions vary substantially during the different phases of the flight. A flight may be considered to consist of 5 phases - take-off, climb, cruise, descent and landing (including operations on the ground). The take-off and climb are the most energy demanding phases and give rise to extensive emissions. For flights over 300 km, the energy use and emissions at take-off, climb, descent and landing may be considered to be constant, independent of the flight distance.

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 --- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Elisabeth Sörheim, Swedish Shipowners' Association, contact person for sea transports in the work of NGM ---
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.

Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vessel, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out.

	Vessels are individuals, which means that the energy use and emissions for different vessels at a given size may vary greatly. The vessels are generally optimised for the shipping route on which it will operate and the cargo it will carry. Generally, smaller vessels in Swedish traffic operate shorter routes, while larger vessels are used for transports to the continent and transocean transports. Data for the individual vessel performing the transport should be used when possible. Data for Swedish flagged vessels that are members of the Swedish Shipowners´ Association may be obtained from Elisabeth Sörheim at the Swedish Shipowners´ Association. ***Type of vessels*** *Freighters* - includes all vessels except RoRo vessels and ferries. Freighters thus include a large variety of different vessels; tankers, container ships, LoLo vessels, bulk vessels, vessels built for a special route etc. Freighters are mainly used for transportation of heavy goods over large distances. The energy use for tankers is generally lower than for other freighters. *RoRo vessels* are used for transportation of different types of load carriers such as trailers, containers etc. The cargo is rolled on the vessel. RoRo vessels generally operate at a higher speed than regular freighters. *Ferries* carry both passengers and goods. The goods are carried in trucks or trains. ***Fuel*** The fuel quality may vary to a large extent between different vessels. Smaller vessels that only operate on Swedish routes generally use better fuels. The main part of freighters in Swedish traffic use heavy fuel oil, with a sulphur content of 2,6 %. Small coastal freighters may however use gas oil with sulphur content of 0,1 %. Gas oil is the most refined type of fuel used in vessels (the maximum sulphur content is 1,5 %). In ferries, low sulphur fuel with sulphur content of 0,5 % is generally used. Differentiated harbour dues on sulphur and NOx emissions were introduced in Sweden 1 January 1998. This will probably result in use of fuels of a better quality, primarily in ferries but also other freighters. ***Reduction of emissions*** The data does not assume the use of any emission reducing measures. Different measures may be taken to reduce the emissions, e.g. water injection may reduce the emissions of NOx by 50%, and adjustments of the engine may reduce NOx emissions by 30 %. Catalytic converters may reduce NOx emissions by 90-100% and HC by 70-80%. Emissions of particles and HC are also reduced. Installation of catalytic converters is however a large investment for the shipowners. There are at present only a few vessels in Swedish traffic that has installed catalytic converters. The other measures constitute a smaller investment, and it is anticipated that the shipowners will chose these techniques to reduce emissions. ***Bulky goods*** Vessels generally handle transportation of large heavy goods over long distances. Some bulky goods are however transported by sea, primarily by RoRo vessels and ferries. The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Travelled distance*** The travelled distance of the goods may be estimated using a Nautic almanac, Lloyd. Since the utilisation level includes empty trips, no compensation in the distance for empty trips needs to be done. ***International sea transports*** When using the data for international traffic, the sulphur emissions should be adjusted, since the fuel quality may vary. Representative sulphur content of fuel used in international traffic is 3,3 %. The energy use and emissions of other parameters may also vary to a large extent depending on the quality of the fuel.
About Data	The data for emissions is derived from specific emission factors for the engine at a constant 80 % engine load. No test cycle was used to obtain the emission factors. There is however a small need for test cycles, since vessels generally operate at constant load on the engine during the sail. The fact that the engine load sometimes is lower than 80 % i.e. when sailing to and from the harbour has been neglected. This part is generally small but complicated. The calculation model may be used to calculate the energy use and emissions for a specific vessel if the loading capacity, installed engine power etc. is known. This information may be obtained from Skeppsregister. See QMetaData for details.
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different

	transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Freighter, 2000-8000 dwt, future

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Freighter, 2000-8000 dwt, future
Functional Unit	1 tonkm, 50-60 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 50 % for tankers and 60% for other freighters. An utilisation level of 50 % for tankers and 60% for other freighters is representative for Swedish domestic traffic if *empty trips are included.*
Process Type	Unit operation
Site	Sweden
Sector	Sea transport
Owner	Sweden
Technical system description	Operation i.e. propulsion of Swedish flagged freighters between 2000 - 8000 dwt (deadweight tonnes) with new technology reducing the energy use and emissions (catalytic converters, energy saving measures etc.). Only members of the Swedish Shipowners´ Association are included. Freighters include all vessels except RoRo vessels and ferries. Freighters thus include a large variety of different vessels; tankers, container ships, LoLo vessels, bulk vessels, vessels built for a special route etc.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water (e.g. discharges of oil) and emissions to ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents new technology, available today but not yet in use.
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 50 % for tankers and 60% for other freighters 60% (including empty trips) *Parameters not considered* -Driving technique -External conditions e.g. climate etc. -Maintenance level of the vessel *Excluded subsystems* -Precombustion, i.e. production and distribution of the fuel. -Maintenance of the vessel (e.g. use of anti fouling) -After-treatment of the vessel

	-Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	See 'Function'.
Method	The energy use and emissions was calculated using *assumptions* on energy saving and emission reducing actions together with data for existing individual vessels with the *lowest energy use and emissions* within the population of Swedish flagged Freighters between 8000 an 2000 dwt, which are members of the Swedish Shipowners' Association vessels. The utilisation level with regard to weight is 50 % for tankers and 60% for other freighters. The assumptions were given by the Swedish Shipowners' Association. The data for energy use and emissions for the vessels that was the basis for the calculation, and a description on how the data was obtained, can be found in the activity with ObjectOfStudy.Name: *Freighter, 8000-2000 dwt* (in this database) or in ''Energi- och emissionsuppgifter för godstransporter''. The minimum value for the energy use and emissions was used in the calculation. The following percentages for the reduction of energy use and emissions was used in the calculation: -Oil consumption: 30 % (by different energy saving measures) -NOx: 93 % (through optimisation of the engine and catalytic converters) -HC: 88 % (by catalytic converters) -CO: 81 % (by catalytic converters) -Particles: 35 % The sulphur content in the fuel was assumed to be 0,09 %. Emissions of SO2 were calculated from the fuel consumption using the sulphur content in the fuel. Emissions of CO2 were calculated from the fuel consumption using the carbon content in the fuel.
Literature Reference	Energi- och emissionsuppgifter för godstransporter i Sverige, Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning 1997, NGM- Nätverket för Godstransporter och Miljön.
Notes	The data is only valid for a flight distance of 600 km The energy use and emissions vary substantially during the different phases of the flight. A flight may be considered to consist of 5 phases - take-off, climb, cruise, descent and landing (including operations on the ground). The take-off and climb are the most energy demanding phases and give rise to extensive emissions. For flights over 300 km, the energy use and emissions at take-off, climb, descent and landing may be considered to be constant, independent of the flight distance.

Flow Data	
General Activity QMetaData	
Date Conceived	1990-01-01 - 1997-01-01
Data Type	Derived, unspecified
Represents	See 'Function'.
Method	The basis for the data are all Swedish flagged freighters larger than 8000 deadweight tonnes, which are members of the Swedish Shipowners' Association. The *quantity value* for all parameters is an average of all vessels in the population. The *minimum value* corresponds to the individual with the lowest energy use and emissions in the population, and the *maximum value* to the individual with the largest energy use and emissions in the population. The *utilisation level* with regard to weight is 50 % for tankers and 60% for other freighters, based on Demker et al. The energy use and emissions per tonkm for each vessel was calculated (see Specific QMetaData for each flow). For each vessel, the loading capacity was stated in deadweight tonnes (Skeppsregister 1995), installed engine power in kW (Skeppsregister 1995) and speed in knots (Lloyds list). The share of two-stroke and four-stroke engines in each vessel was determined by the size of the vessel according to Alexandersson. All vessels in the population were then used to calculate an average value.

Literature Reference	Alexandersson, A., *Sjöfartens utsläpp av avgaser*, MariTerm, TFB-rapport 1991:18 Demker, G. et al. *Miljöeffekter av transportmedelsval för godstransporter*, MariTerm, KFB-rapport, 1994:6 *Skeppsregister 1995*, Swedish Shipowner Association Sjöbris, A., Flodström, E. *Emissions och energivärderingsprinciper för transportsystem*, MariTerm, KFB-rapport 1994:9 *Lloyds list*, 1996
Notes	The data is only valid for a flight distance of 600 km The energy use and emissions vary substantially during the different phases of the flight. A flight may be considered to consist of 5 phases - take-off, climb, cruise, descent and landing (including operations on the ground). The take-off and climb are the most energy demanding phases and give rise to extensive emissions. For flights over 300 km, the energy use and emissions at take-off, climb, descent and landing may be considered to be constant, independent of the flight distance.

	Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vessel, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. Vessels are individuals, which means that the energy use and emissions for different vessels at a given size may vary greatly. The vessels are generally optimised for the shipping route on which it will operate and the cargo it will carry. Generally, smaller vessels in Swedish traffic operate shorter routes, while larger vessels are used for transports to the continent and transocean transports. Data for the individual vessel performing the transport should be used when possible. Data for Swedish flagged vessels that are members of the Swedish Shipowners´ Association may be obtained from Elisabeth Sörheim at the Swedish Shipowners´ Association. ***Type of vessels*** *Freighters* - includes all vessels except RoRo vessels and ferries. Freighters thus include a large variety of different vessels; tankers, container ships, LoLo vessels, bulk vessels, vessels built for a special route etc. Freighters are mainly used for transportation of heavy goods over large distances. The energy use for tankers is generally lower than for other freighters. *RoRo vessels* are used for transportation of different types of load carriers such as trailers, containers etc. The cargo is rolled on the vessel. RoRo vessels generally operate at a higher speed than regular freighters. *Ferries* carry both passengers and goods. The goods are carried in trucks or trains. ***Fuel*** The fuel quality may vary to a large extent between different vessels. Smaller vessels that only operate on Swedish routes generally use better fuels. The main part of freighters in Swedish traffic use heavy fuel oil, with a sulphur content of 2,6 %. Small coastal freighters may however use gas oil with sulphur content of 0,1 %. Gas oil is the most refined type of fuel used in vessels (the maximum sulphur content is 1,5 %). In ferries, low sulphur fuel with sulphur content of 0,5 % is generally used. Differentiated harbour dues on sulphur and NOx emissions were introduced in Sweden 1 January 1998. This will probably result in use of fuels of a better quality, primarily in ferries but also other freighters. ***Reduction of emissions*** The data does not assume the use of any emission reducing measures. Different measures may be taken to reduce the emissions, e.g. water injection may reduce the emissions of NOx by 50%, and adjustments of the engine may reduce NOx emissions by 30 %. Catalytic converters may reduce NOx emissions by 90-100% and HC by 70-80%. Emissions of particles and HC are also reduced. Installation of catalytic converters is however a large investment for the shipowners. There are at present only a few vessels in Swedish traffic that has installed catalytic converters. The other measures constitute a smaller investment, and it is anticipated that the shipowners will chose these techniques to reduce emissions. ***Bulky goods*** Vessels generally handle transportation of large heavy goods over long distances. Some bulky goods are however transported by sea, primarily by RoRo vessels and ferries. The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Travelled distance*** The travelled distance of the goods may be estimated using a Nautic almanac, Lloyd. Since the utilisation level includes empty trips, no compensation in the distance for empty trips needs to be done. ***International sea transports*** When using the data for international traffic, the sulphur emissions should be adjusted, since the fuel quality may vary. Representative sulphur content of fuel used in international traffic is 3,3 %. The energy use and emissions of other parameters may also vary to a large extent depending on the quality of the fuel.
	About Data	The data for emissions is derived from specific emission factors for the engine at a constant 80 % engine load. No test cycle was used to obtain the emission factors. There is however a small need for test cycles, since vessels generally operate at constant load on the engine during the sail. The fact that the engine load sometimes is lower than 80 % i.e. when sailing to and from the harbour has been neglected. This part is generally small but complicated. The calculation model may be used to calculate the energy use and emissions for a specific vessel if the loading capacity, installed engine power etc. is known. This information may be obtained from Skeppsregister. See QMetaData for details.
	Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at

	the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Freighter, larger than 8000 dwt, future

Administrative	
Finished	Y
Date Completed	1997-11-19

Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Freighter, larger than 8000 dwt, future
Functional Unit	1 tonkm, 50-60 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 50 % for tankers and 60% for other freighters. An utilisation level of 50 % for tankers and 60% for other freighters is representative for Swedish domestic traffic if *empty trips are included.*
Process Type	Unit operation
Site	Sweden
Sector	Sea transport
Owner	Sweden
Technical system description	Operation i.e. propulsion of Swedish flagged freighters larger than 8000 dwt (deadweight tonnes) with new technology reducing the energy use and emissions (catalytic converters, energy saving measures etc.). Only members of the Swedish Shipowners´ Association are included. Freighters include all vessels except RoRo vessels and ferries. Freighters thus include a large variety of different vessels; tankers, container ships, LoLo vessels, bulk vessels, vessels built for a special route etc.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO_2 -tax regulated CO_2. Diffuse emissions to air, emissions to water (e.g. discharges of oil) and emissions to ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents new technology, available today but not yet in use.
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 50 % for tankers and 60% for other freighters 60% (including empty trips) *Parameters not considered* -Driving technique -External conditions e.g. climate etc. -Maintenance level of the vessel

	Excluded subsystems -Precombustion, i.e. production and distribution of the fuel. -Maintenance of the vessel (e.g. use of anti fouling) -After-treatment of the vessel -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	See 'Function'.
Method	The energy use and emissions was calculated using *assumptions* on energy saving and emission reducing actions together with data for existing individual vessels with the *lowest energy use and emissions* within the population of Swedish flagged freighters larger than 8000 dwt, which are members of the Swedish Shipowners' Association vessels. The utilisation level with regard to weight is 50 % for tankers and 60% for other freighters. The assumptions were given by the Swedish Shipowners' Association. The data for energy use and emissions for the vessels that was the basis for the calculation, and a description on how the data was obtained, can be found in the activity with ObjectOfStudy.Name: *Freighter, larger than 8000 dwt* (in this database) or in ''Energi- och emissionsuppgifter för godstransporter''. The minimum value for the energy use and emissions was used in the calculation. The following percentages for the reduction of energy use and emissions was used in the calculation: -Oil consumption: 30 % (by different energy saving measures) -NOx: 93 % (through optimisation of the engine and catalytic converters) -HC: 88 % (by catalytic converters) -CO: 81 % (by catalytic converters) -Particles: 35 % The sulphur content in the fuel was assumed to be 0,09 %. Emissions of SO2 were calculated from the fuel consumption using the sulphur content in the fuel. Emissions of CO2 were calculated from the fuel consumption using the carbon content in the fuel.
Literature Reference	Energi- och emissionsuppgifter för godstransporter i Sverige, Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning 1997, NGM- Nätverket för Godstransporter och Miljön.
Notes	The data is only valid for a flight distance of 600 km The energy use and emissions vary substantially during the different phases of the flight. A flight may be considered to consist of 5 phases - take-off, climb, cruise, descent and landing (including operations on the ground). The take-off and climb are the most energy demanding phases and give rise to extensive emissions. For flights over 300 km, the energy use and emissions at take-off, climb, descent and landing may be considered to be constant, independent of the flight distance.

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 --- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Elisabeth Sörheim, Swedish Shipowners' Association, contact person for sea transports in the work of NGM ---
Intended User	Suppliers and buyers of goods

General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.

Flow Data	
General Activity QMetaData	
Date Conceived	1990-01-01 - 1997-01-01
Data Type	Derived, unspecified
Represents	See 'Function'.
Method	The basis for the data are all Swedish flagged freighters smaller than 2000 deadweight tonnes (and larger than 300 BRT), which are members of the Swedish Shipowners' Association. The *quantity value* for all parameters is an average of all vessels in the population. The *minimum value* corresponds to the individual with the lowest energy use and emissions in the population, and the *maximum value* to the individual with the largest energy use and emissions in the population. The *utilisation level* with regard to weight is 50 % for tankers and 60% for other freighters, based on Demker et al. The energy use and emissions per tonkm for each vessel was calculated (see Specific QMetaData for each flow).

	For each vessel, the loading capacity was stated in deadweight tonnes (Skeppsregister 1995), installed engine power in kW (Skeppsregister 1995) and speed in knots (Lloyds list). The share of two-stroke and four-stroke engines in each vessel was determined by the size of the vessel according to Alexandersson. All vessels in the population were then used to calculate an average value.
Literature Reference	Alexandersson, A., *Sjöfartens utsläpp av avgaser*, MariTerm, TFB-rapport 1991:18 Demker, G. et al. *Miljöeffekter av transportmedelsval för godstransporter*, MariTerm, KFB-rapport, 1994:6 *Skeppsregister 1995*, Swedish Shipowner Association Sjöbris, A., Flodström, E. *Emissions och energivärderingsprinciper för transportsystem*, MariTerm, KFB-rapport 1994:9 *Lloyds list*, 1996
Notes	The data is only valid for a flight distance of 600 km The energy use and emissions vary substantially during the different phases of the flight. A flight may be considered to consist of 5 phases - take-off, climb, cruise, descent and landing (including operations on the ground). The take-off and climb are the most energy demanding phases and give rise to extensive emissions. Sector	Sea transport
Owner	Sweden
Technical system description	Operation i.e. propulsion of Swedish flagged freighters smaller than 2000 dwt (deadweight tonnes) with new technology reducing the energy use and emissions (catalytic converters, energy saving measures etc.). Only members of the Swedish Shipowners´ Association are included. Freighters include all vessels except RoRo vessels and ferries. Freighters thus include a large variety of different vessels; tankers, container ships, LoLo vessels, bulk vessels, vessels built for a special route etc..

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO_2 -tax regulated CO_2. Diffuse emissions to air, emissions to water (e.g. discharges of oil) and emissions to ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents new technology, available today but not yet in use.
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 50 % for tankers and 60% for other freighters 60% (including empty trips) *Parameters not considered* -Driving technique

	-External conditions e.g. climate etc. -Maintenance level of the vessel *Excluded subsystems* -Precombustion, i.e. production and distribution of the fuel. -Maintenance of the vessel (e.g. use of anti fouling) -After-treatment of the vessel -Handling of production rests

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	See 'Function'.
Method	The energy use and emissions was calculated using *assumptions* on energy saving and emission reducing actions together with data for existing individual vessels with the *lowest energy use and emissions* within the population of Swedish flagged freighters smaller than 2000 dwt, which are members of the Swedish Shipowners' Association vessels. The utilisation level with regard to weight is 50 % for tankers and 60% for other freighters%. The assumptions were given by the Swedish Shipowners' Association. The data for energy use and emissions for the vessels that was the basis for the calculation, and a description on how the data was obtained, can be found in the activity with ObjectOfStudy.Name: *Freighter, smaller than 2000dwt* (in this database) or in ''Energi- och emissionsuppgifter för godstransporter''. The minimum value for the energy use and emissions was used in the calculation. The following percentages for the reduction of energy use and emissions was used in the calculation: -Oil consumption: 30 % (by different energy saving measures) -NOx: 93 % (through optimisation of the engine and catalytic converters) -HC: 88 % (by catalytic converters) -CO: 81 % (by catalytic converters) -Particles: 35 % The sulphur content in the fuel was assumed to be 0,09 %. Emissions of SO2 were calculated from the fuel consumption using the sulphur content in the fuel. Emissions of CO2 were calculated from the fuel consumption using the carbon content in the fuel.
Literature Reference	Energi- och emissionsuppgifter för godstransporter i Sverige, Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning 1997, NGM- Nätverket för Godstransporter och Miljön.
Notes	The data is only valid for a flight distance of 600 km The energy use and emissions vary substantially during the different phases of the flight. A flight may be considered to consist of 5 phases - take-off, climb, cruise, descent and landing (including operations on the ground). The take-off and climb are the most energy demanding phases and give rise to extensive emissions. For flights over 300 km, the energy use and emissions at take-off, climb, descent and landing may be considered to be constant, independent of the flight distance.

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Elisabeth Sörheim, Swedish Shipowners' Association, contact person for sea transports in the work of NGM --
Intended User	Suppliers and buyers of goods

General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Sörheim, Elisabeth - The Swedish Shipowners Association, Box 53046, S-400 14 Göteborg .
Reviewer	
Applicability	The ambition with the data was to get a picture of future energy use and emissions for Swedish flagged freighters smaller than 2000 dead weight tonnes. The data represents new technology (catalytic converters, energy saving measures etc), not yet in regular use. There are at present only a few vessels in Swedish traffic that has installed catalytic converters, since installation of catalytic converters is a large investment for the shipowners.
About Data	The data is based on assumptions on different energy saving and emission reducing actions together with data for existing vessels in Swedish traffic with the lowest energy use and emissions. The data was compiled by the Swedish Shipowners´ Association. See Flow QMetaData for further information.
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Fuel gas electricity energy system, EPD-version

Administrative	
Finished	Y
Date Completed	1996-10
Copyright	Bundesamt für Energie, Bern
Availability	Public

Technical System	
Name	Fuel gas electricity energy system, EPD-version
Functional Unit	1 TJ net electricity from power plant
Functional Unit Explanation	The generation of 1 TJ (1 000 000 000 000 J) net electricity (i.e. electricity need in the power plant has been supplied for by the plant istself). Electricity distribution and distribution losses are not accounted for, i.e. not for this particular unit process. Data about distribution and its losses may however be found in the original study.
Process Type	Cradle to grave
Site	UCTPE countries Europe
Sector	Grid electricity and district heat
Owner	UCTPE countries Europe
Technical system description	Reported figures are based on data from a LCI-study performed at ETH, Zürich and Paul Scherrer Institut, Villigen, ''Ökoinventare von Energiesystemen'', 3rd edition 1996 and adapted to the demands of the EPD-guidelines (Environmental Product Declaration guidelines in Sweden). -- Brief description -- The phases inventoried in ETH's life cycle study of electricity generation with fuel gas (74,5% natural gas 36 MJ/m3, 6,9% coke oven gas 18 MJ/m3, 18,6% blast furnace gas 3,3 MJ/m3) are: exploration of natural gas, extraction (onshore and offshore), processing, long distance transport and storage, regional distribution and power plant operation. The average situation in the UCPTE* region in 1994 concerning the origin of the gas, compression and transport, processing (of gas with more or less sulphur content), distribution, power plant operation etc. is described. About 15% of the natural gas is extracted together with crude oil and 20% of natural gas used in the UCPTE is extracted offshore. Coke oven gas is produced in a cokery out of stone coal but is not described in detail in this documentation (see metadata in ''Stone coal electricity energy system, EPD-version'' and the original ETH study) but blast furnace gas is seen as a byproduct in steel production and is not charged with any environmental impact for its supply in this study. All subsystems are described on a ''cradle-to-grave'' basis, including the main stages, i.e. data concerning consumption of resources, waste handling and emissions is included for the manufacturing of main materials and energyware used in the lifecycle. -- Detailed description -- Exploration of natural gas

Drilling activities during exploration of natural gas have been inventoried regarding use of energyware, drilling chemicals, water, steel and concrete (coating of drilling holes) and use of land/sea bed (not included in the figures reported here, see other boundaries). Besides emissions arising due to use of energyware also emissions of methane and other volatile organic compounds from the drilling holes are included. Natural gas/crude oil emanating in drilling test is burnt, emissions are included.
Offshore exploration leads to emissions of drilling chemicals and drilling sludge to the sea, though a lot of it is cleaned on the platform before it is emitted. Other emissions to the sea are heavy metals from the drilled sea bed, oil and intraformation water. Some of the drilling chemicals and sludge is brought to the shore as waste.
Waste of onshore activities are of the same kind. It is put in landfills, in land farming or casted (emissions from these processes are included).

Extraction of natural gas
Average on- and offshore extraction has been inventoried regarding construction and demolition of platforms, towers, pipelines etc., use of energyware, materials (steel and concrete) and land/sea bed.
A first processing step of natural gas to remove sulphur (for gases with a high sulphur content, H2S > 1% by volume) is included as well as flaring of gas, leaks, blow-outs and low pressure venting (emissions of mercury and radioactive radon are accounted for since these elements are found in the gas).
Compression is used in the extracting process, for transportation to processing plant (onshore about 50 km) and for compensation of pressure losses in the processing plant. Gas turbines are used (10-20 MW) driven by not yet processed natural gas, raw gas.
Extraction of gas together with crude oil gives a higher energyware consumption than extraction of natural gas alone due to larger compression and processing need.
Production of production chemicals, for ex. anticorrosives, and drilling chemicals as well as emissions of those chemicals is included based on rough estimations.
Onshore, most of the intraformation water is assumed to be pumped into hollows deep in the ground the rest is led into a fresh water recipient. Offshore most of the intraformation water is emitted to the sea.
Shipping of supplies is included.
Production waste consists of scale i.e. mineral deposits in equipment and pipelines. Scale is low level radioactive.

Processing of natural gas
Processing implies removal of water and oil, higher hydrocarbons, sulphur (efficiency 98%), mercury and radon as well as gas drying. Processing of gas with a higher sulphur content is often done onshore and is supplied by grid electricity while gas with a low sulphur content often is processed in the field (supply by gas turbines). Construction phase and operation phase is included (also flaring and leaks). Processed gas has a lower heating value of 34.4 MJ/m3 (density 0.8 kg/m3, 70% methane, sulphur content 0,002 g/m3).

Long-distance transports of natural gas
The average transport situation has been scanned. Transport in pipeline implies compression of the gas in several compressor stations with several natural gas driven gas turbines (10-20 MW). The average natural gas flow varies with pipeline, 0,77-1 milion m3 per h. Average transport distances are 800 km from the Netherlands, 1500 km from Norway, 800 km from Germany, 2500 km from Algeria and 6000 km from the former Soviet Union. Leakage rates for Russian natural gas are 0,5% for gas production and 1,5% for long distance transportation to Europe. For long distance transportation from other countries, a leakage rate of 0.01% per 1000 km is applied.
Construction of pipelines and seasonal storages (about 10% /year of the gas is stored), leaks, condensate separators, incineration of condensate and inspection flights are included.
64% of imported gas from Algeria is liquified (LNG): 15% of this gas is consumed for cooling of the gas. Transport is done by ship. Construction of gas containers is included but not of the ships themselves. Leaks are included.

Regional distribution of natural gas
The regional distribution implies gauging stations and pressure reducing stations, no further compressor stations are needed since the pressure from the long distance pipelines is enough. The regional distribution is however charged by some compression work done in the long distance pipeline system (0,2% of gas transported in the regional distribution network). The average transportation distance is set to 100 km. Medium gas flow: 30,3 TJ/km. Inspections and leaks are included.

Power plant for fuel gas
Fuel gas power plants are mainly used as top load plants with a low medium load (20%). Operation time is about 1800 h/year and electric efficiency is 39%. Fuel mix has been calculated from national statistics (including natural gas, coke oven gas and blast furnace gas) and fuel used for heat production (3,3% of total amount fuel gas used in the UCPTE) has been substracted. Construction and demolition of a 100 MWe steam turbin power plant has been inventoried. Data concerning operation emissions, water use and wastes has been found in literature and in public statistics and has been adapted to the UCPTE fuel gas mix.

* Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.

System Boundaries

Nature Boundary	Used materials and energyware have been followed from extraction and processing of natural resources. Manufacturing processes for the use of recycled material are accounted for. Emissions from energyware use in manufacturing processes and transports (infrastructure and vehicle construction included) are considered as well as emissions from landfills (infrastructure included) where waste material is disposed of. Waste material supposed to be recycled are outputs of the system (i.e. those recycling processes are not included). ETH's LCI-results comprise all parameters received during inventory and calculation, i.e. no selection has been made by ETH. Vattenfall's criterion in selecting and aggregating ETH's LCI-results for electricity generation in the UCPTE region has been to make the figures usable as general electricity LCI data in EPDs according to Miljöstyrningsrådets guidelines. Especially parameters (emissions) which have established impact indices - accepted by the EPD system - for one or several environmental impact categories, have been picked out and aggregated as far possible. But also metal and energyware resources have been included, as well as waste, in spite of all waste handling processes related to this dataset being included with respect to use of resources and emissions. The latter is an adaption to other LCI data for electricity generation where waste amounts are reported (since those flows have not been followed to the grave). Since ETH claimes that most of the figures regarding metal emissions have an undefined amount of datagaps all metal emissions are aggregated except for a few which are specified separatly since they are reported for most processes in the lifecycle. Metals are reported as elements although they often are part of compounds. Measuring methods often just give the amounts of the different elements found. All hydrocarbons to water are aggregated to one parameter as well as halogenated organics, since no indices exist (that are accepted by the EPD system so far) for characterisation of the individual substances.
Time Boundary	Most of statistic figures used are from 1990 to 1994. For the calulation of the UCPTE gas electricity, fuel use in Europe of the year 1993 has been used. Data concerning material, chemical and energyware use are partly older. Figures concerning other fuel extraction and processing represent an average of the early nineties. Descriptions and figures of different technical processes come from literature, contractors, public and private institutions and describe the situation of the late eighties. Electricity used during the lifecycle has been assumed to be a mix based on the average generation in the UCPTE* countries between 1990-94 (to level off the large variations in hydro power production over the years). All processes, also those conducted in the past, have been assumed to use average technology of the early nineties. Different technical lifetimes/reference times for different parts and materials of the studied systems have been used as follows: Pipelines in the gas field 30 years Pipelines, long distance 50 years Pipelines, regional distribution 40 years Power plant 30 years * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Geographical Boundary	Most important supplier countries of natural gas in the UCPTE are the Netherlands (39%), the states of the former Soviet Union (22%), Algeria (11%), Norway (9%) and Germany (7%). The rest comes mainly from Italy, France and Denmark (these countries are not included in this study, approximated with German figures). Only the Swiss regional distribution net for natural gas has been inventoried as a whole. Resulting figures have been adapted to UCPTE* conditions. Processes conducted outside the UCPTE* region are supposed to be supplied with UCPTE* electricity. Data concerning the use of resources, emissions and waste in connection with manufacturing processes mainly originate from sources in Switzerland, Germany and other western European countries. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.

Other Boundaries	Dismantling process of platforms is not included and the whole platform including drillhole mantelings and pipelines are assumed to be deposited, i.e. no recycling. Manufacture of needed chemicals in the processing plant for natural gas is neglected as well as the their transport. Manufacturing processes of components and machines have been approximated with 50% of the energyware used to produce contained materials. Energyware figures concerning material production come from literature and have assumed to be a mix of 10% UCPTE electricity, 45% oil and 45% natural gas. This approximation has been confirmed in more thorough calculations in ETH:s LCA for coal power. The ETH study comprises figures concerning use of land, usable content in water storages and amount of turbine water which have not been reported here. The two latter have been excluded due to lack of corresponding data in comparable studies. Use of land has been excluded here because of ETH's advanced approach. Land is divided into two main groups - land and sea - which are subdivided into 4 categories each. Land Criterion Category Natural human impact not larger than other species' since the industrial revolution I Modified human impact larger than other species', low degree of cultivation II Cultivated human impact larger than other species', large degree of cultivation III Built upon dominated by buildings, roads, dams, mines etc. IV Category I is not used in the study. State of land before, during and after exploitation is of interest. If a piece of land is used again after some kind of exploitation it will either end up in the same category or in a higher one. ETH takes into account not only the land used during the technical lifetime of the studied system but also during the construction phase and during the time it takes to restore the land. They express use of land in the unit m2year which is different from comparable Swedish studies (m2). See times for restoration of land below: From category IV to category III 5 years From category III to category II 50 years From category II to category I 100 000 years (For uranium mines the restoration time to category II is 80'000 years due to elevated radiation caused by long-living radioactive compounds.) ETH specifies about 160 radioactive isotopes emitted to air and water. Radioactive emissions reported here are picked out in accordance with SETAC working group report on data quality and data availability (to be published in 2001). Big accidents occuring seldomly are not included.The threshold is fixes at 10 accidents per year if one energy carrier/system (e.g. oil) would cover the entire primary energy demand of the world.
Allocations	Allocation of pipelines to the produced amount of gas is difficult. The total gas distribution network has been inventoried and related to the total amount of transported gas in 1994 assuming that this is representative. Allocation between natural gas and crude oil when extracted together has been conducted according to the lower heating value. Allocation between electricity and heat in fuel gas power plants has been done according to exergy. The cutoff-method has been used for material use, i.e. 100% of the environmental load for virgin and recycled material used in the lifecycle is included whereas no environmental load has been considered for materials leaving the system to be recycled. Landfill processes and waste incineration, however, are included for waste arising during the lifecycle.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1985 to 1995
Data Type	Derived, unspecified
Represents	Average electricity generation with fuel gas in the UCTPE countries in the early nineties.
Method	The data has been adapted from the Ökoinventare von Energiesystemen, ETH Zürich 1996 and is an aggregation of the LCI results for the module ''Electricity from fuel gas power plant UCPTE-mix'' (Strom ab Brenngas-Kraftwerk UCPTE-Mix).
Literature Reference	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz, Environmental Life-Cycle Inventories of Energy Systems An Environmental Database for the Accounting of Energy Consumption in Product Life-Cycle Assessment and the Comparative

	Assessment of Energy systems Prof. Dr. P. Suter, R. Frischknecht, et al Swiss Federal Institute of Technology, Zürich R. Dones, U. Gantner Paul Scherrer Institute, Villigen/Würenlingen
Notes	The data is only valid for a flight distance of 600 km The energy use and emissions vary substantially during the different phases of the flight. A flight may be considered to consist of 5 phases - take-off, climb, cruise, descent and landing (including operations on the ground). The take-off and climb are the most energy demanding phases and give rise to extensive emissions. For flights over 300 km, the energy use and emissions at take-off, climb, descent and landing may be considered to be constant, independent of the flight distance.

Flow Table and Specific Meta Data

QMetaData	*Direction*	*FlowType*	*Substance*	*Quantity*	*Min*	*Max*	*Unit*	*Environment*	*Geography*
	Input	Natural resource	Bauxite	15.5			kg	Ground

About Inventory	
Publication	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz. ETH, Eidgenössische Technische Hochschule, Zürich, Gruppe Energie - Stoffe - Umwelt (ESU), Paul Scherrer Institut, Villigen/Würenlingen, Sektion Ganzheitliche Systemanalysen Available on CD-ROM with full documentation (in German) at http://www. energieforschung.ch -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by (see also Notes): Rolf Frischknecht, ESU-services, Switzerland Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	Original study of ETH: LCA pra
General Purpose	The purpose of the ETH study was to examine a number of energy systems quantitatively and to the same extent with respect to environmental issues during their lifecycles. The results can be used in lifecycle assessments, as basis information in decisionmaking regarding environmental optimisation or in working with municipal energy plans. Vattenfalls purpose - as a commissioner of putting ETH:s data into Spine format with metadata - is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines. Data is supposed to be used together with IEA statistics about electricity generation mixes in the OECD countries/regions.
Detailed Purpose	ETH:s aim was to describe the average situation in Europe concerning electricity generation with fuel gas (a mix of natural gas, coke oven gas and blast furnace gas). With the help of assumptions and simplifications following phases of the life cycle are described: exploration (on- and offshore) extraction (on- and offshore), processing, long-distance transports, distribution and power plant.
Commissioner	BEW, PSEL - Bundesamt für Energiewirtschaft, Projekt- und Studienfonds der Elektrizitätswirtschaft .
Practitioner	Rolf Frischknecht et al - ETH, Eidgenössische Technische Hochschule, Institut für Energietechnik, Zürich and Paul Scherrer Institut, Sektion Ganzheitliche Systemanalyse, Villingen/Würenlingen .
Reviewer	None, see further under notes -
Applicability	Data reported here is supposed to be representative for fuel gas (natural gas, coke oven gas and blas furnace gas) electricity generation in the UCPTE countries in 1994. This set of data is aggregated and documented in accordance with the Swedish EPD-guidelines to be used in combination with IEA statistics concerning electricity generation mixes in OECD countries and regions together with other datasets - based on the ETH study - describing other power generation systems. The EPD-adapted power generation systems in Spine format are named as follows: Fuel gas electricity energy system, EPD-version Biofuel electricity energy system, EPD-version Hydro electricity energy system, EPD-version Lignite electricity energy system, EPD-version Nuclear electricity energy system, EPD-version Stone coal electricity energy system, EPD-version Wind electricity energy system, EPD-version IEA statistics for generation mixes 1998 exist in Spine format for the following 30 countries/regions: OECD total OECD North America OECD Pacific OECD Europe European Union Australia Austria Belgium Canada Czech Rpublic Denmark Finland France Germany Greece

	Hungary Iceland Ireland Italy Japan Korea Luxembourg Mexico Netherlands New Zealand Norway Poland Portugal Spain Sweden Switzerland Turkey United Kingdom United States
About Data	Reliability of data put into this lifecycle study: More reliable share of on- and offshore extraction amounts of flaring (allocation betw. oil and gas assumed) energyware consump. in extraction and processing phase constr. of extraction and processing plants transportation concerning construction aggregation to the UCPTE-mix for power plants fuel gas mix (natural, coke oven and blast furn. gas) conventional emissions from power plant Less reliable drilling during exploration and extraction amounts and concentrations in intraformation water processing of gas (except energyware) cleaning of trace elements in proc. plant area use gas leakage in the former Soviet Union lifetime of pipelines average gas flows in pipelines fuel chain of Algerian natural gas especially LNG route emissions of N2O, NMVOC, CO Material manufacturing processes have been inventoried with a low degree of exactitude (except for steel, cement, aluminium, copper, bitumen, and platinum groug metals for which rather detailed LCI data are provided. Results are reported with three figures, but it is stated in the original source that this does not mean that accuracy is that high (Part III, p.16). For references and sources of reported figures see further under Function, Nature boundary, Geographical boundaries, Publication, Notes and General metadata.
Notes	Reviewer of this specification of ETH:s data and metadata has been: Dr. Rolf Frischknecht, ESU-services (earlier at ETH) - approval of aggregation of figures and of Vattenfall's interpretation ot the documentation Ann-Christin Pålsson, CPM - review of documentation quality according to the CPM data documentation requirements. The technical committee of the Swedish Environmental Management Council - approval of method and aggregation of parameters Project Management of the ETH study, 3rd edition: Professor, Dr. P. Suter and R. Frischknecht, ETH Editorial staff of the 1st edition: R. Frischknecht, P. Hofstetter, I. Knoepfel, M. Ménard, ETH R. Dones, E. Zollinger, Paul Scherrer Institut Authors of the 1st edition: N. Attinger, T. Baumann, G. Doka, R. Dones, R. Frischknecht, H.-P. Gränicher, C. Grasser, P. Hofstetter, I. Knoepfel, M. Ménard, H. Müller, M. Vollmer, E. Walder, E. Zollinger Authors of the überarbeitung, 3rd edition: U. Bollens, S, Bosshart, M. Ciot, L. Ciseri, G. Doka, R. Frischknecht, R Hischier, A. Martin, ETH R. Dones, U. Gantner, Paul Scherrer Institut -- --- Changes made to the data set after publishing in SPINE@CPM--- >>> 6 June 2001: <<< Changes made by Ann-Christin Pålsson, CPM based on discussions with Caroline Setterwall, Vattenfall AB. Comments: The following changes has been made in the nomenclature for in- and outflows: Mangane in ore -> changed to: Manganese in ore CH4 -> changed to: Methane (to be in accordance with the nomenclature specified in CPM

	report 2000:2) CN -> changed to: CN- Stone coal -> changed to: Hard coal (to be in accordance with the nomenclature specified in CPM report 2000:2) Other metals -> changed to: Metals Explanations of nomenclature (inserted in Notes for the specific flows): - CN- is Cyanide ion - Reactive waste deposit is waste at landfill that is still reactive. - Inert waste deposit is waste at landfill that are inert. Additional clarifications: - Note that the flows of waste in the table of in- and outflows are internal flows, i.e. they do NOT cross the system boundaries. All waste handling processes is included in the study with respect to use of resources and emissions. - Radioactive waste is accounted for in cubic metres. The product specific requirements for electricity and district heating generation (PSR 1998:1) in the Swedish EPD system states that waste shall be accounted for in gram. However, no conversion factors were given in the study. There are also no general conversion factors that are commonly used.

SPINE LCI dataset: Fuel gas electricity energy system, ETH - full version

Technical System	
Name	Fuel gas electricity energy system, ETH - full version
Functional Unit	1 TJ net electricity from power plant
Functional Unit Explanation	The generation of 1 TJ (1 000 000 000 000 J) net electricity (i.e. electricity need in the power plant has been supplied for by the plant istself). Electricity distribution and distribution losses are not accounted for, i.e. not for this particular unit process. Data about distribution and its losses may however be found in the original study.
Process Type	Cradle to grave
Site	UCTPE countries Europe
Sector	Grid electricity and district heat
Owner	UCTPE countries Europe
Technical system description	Reported figures come from a LCI-study performed at ETH, Zürich and Paul Scherrer Institut, Villigen, ''Ökoinventare von Energiesystemen'', 3rd edition 1996. Brief description The phases inventoried in ETH's life cycle study of electricity generation with fuel gas (74,5% natural gas 36 MJ/m3, 6,9% coke oven gas 18 MJ/m3, 18,6% blast furnace gas 3,3 MJ/m3) are: exploration of natural gas, extraction (onshore and offshore), processing, long distance transport and storage, regional distribution and power plant operation. The average situation in the UCPTE* region in 1994 concerning the origin of the gas, compression and transport, processing (of gas with more or less sulphur content), distribution, power plant operation etc. is described. About 15% of the natural gas is extracted together with crude oil and 20% of natural gas used in the UCPTE is extracted offshore. Coke oven gas is produced in a cokery out of stone coal but is not described in detail in this documentation (see metadata in ''Stone coal electricity energy system, EPD-version'' and the original ETH study) but blast furnace gas is seen as a byproduct in steel production and is not charged with any environmental impact for its supply in this study. All subsystems are described on a ''cradle-to-grave'' basis, including the main stages, i.e. data concerning consumption of resources, waste handling and emissions is included for the manufacturing of main materials and energyware used in the lifecycle.

Detailed description

Exploration of natural gas
Drilling activities during exploration of natural gas have been inventoried regarding use of energyware, drilling chemicals, water, steel and concrete (coating of drilling holes) and use of land/sea bed. Besides emissions arising due to use of energyware also emissions of methane and other volatile organic compounds from the drilling holes are included. Natural gas/crude oil emanating in drilling test is burnt, emissions are included.
Offshore exploration leads to emissions of drilling chemicals and drilling sludge to the sea, though a lot of it is cleaned on the platform before it is emitted. Other emissions to the sea are heavy metals from the drilled sea bed, oil and intraformation water. Some of the drilling chemicals and sludge is brought to the shore as waste.
Waste of onshore activities are of the same kind. It is put in landfills, in land farming or casted (emissions from these processes are included).

Extraction of natural gas
Average on- and offshore extraction has been inventoried regarding construction and demolition of platforms, towers, pipelines etc., use of energyware, materials (steel and concrete) and land/sea bed.
A first processing step of natural gas to remove sulphur (for gases with a high sulphur content, H_2S > 1% by volume) is included as well as flaring of gas, leaks, blow-outs and low pressure venting (emissions of mercury and radioactive radon are accounted for since these elements are found in the gas).
Compression is used in the extracting process, for transportation to processing plant (onshore about 50 km) and for compensation of pressure losses in the processing plant. Gas turbines are used (10-20 MW) driven by not yet processed natural gas, raw gas.
Extraction of gas together with crude oil gives a higher energyware consumption than extraction of natural gas alone due to larger compression and processing need.
Production of production chemicals, for ex. anticorrosives, and drilling chemicals as well as emissions of those chemicals is included based on rough estimations.
Onshore, most of the intraformation water is assumed to be pumped into hollows deep in the ground the rest is led into a fresh water recipient. Offshore most of the intraformation water is emitted to the sea.
Shipping of supplies is included.
Production waste consists of scale i.e. mineral deposits in equipment and pipelines. Scale is low level radioactive.

Processing of natural gas
Processing implies removal of water and oil, higher hydrocarbons, sulphur (efficiency 98%), mercury and radon as well as gas drying. Processing of gas with a higher sulphur content is often done onshore and is supplied by grid electricity while gas with a low sulphur content often is processed in the field (supply by gas turbines). Construction phase and operation phase is included (also flaring and leaks). Processed gas has a lower heating value of 34.4 MJ/m3 (density 0.8 kg/m3, 70% methane, sulphur content 0,002 g/m3).

Long-distance transports of natural gas
The average transport situation has been scanned. Transport in pipeline implies compression of the gas in several compressor stations with several natural gas driven gas turbines (10-20 MW). The average natural gas flow varies with pipeline, 0,77-1 milion m3 per h. Average transport distances are 800 km from the Netherlands, 1500 km from Norway, 800 km from Germany, 2500 km from Algeria and 6000 km from the former Soviet Union. Leakage rates for Russian natural gas are 0,5% for gas production and 1,5% for long distance transportation to Europe. For long distance transportation from other countries, a leakage rate of 0.01% per 1000 km is applied.
Construction of pipelines and seasonal storages (about 10% /year of the gas is stored), leaks, condensate separators, incineration of condensate and inspection flights are included.
64% of imported gas from Algeria is liquified (LNG): 15% of this gas is consumed for cooling of the gas. Transport is done by ship. Construction of gas containers is included but not of the ships themselves. Leaks are included.

Regional distribution of natural gas
The regional distribution implies gauging stations and pressure reducing stations, no further compressor stations are needed since the pressure from the long distance pipelines is enough. The regional distribution is however charged by some compression work done in the long distance pipeline system (0,2% of gas transported in the regional distribution network). The average transportation distance is set to 100 km. Medium gas flow: 30,3 TJ/km. Inspections and leaks are included.

Power plant for fuel gas
Fuel gas power plants are mainly used as top load plants with a low medium load (20%). Operation time is about 1800 h/year and electric efficiency is 39%. Fuel mix has been calculated from national statistics (including natural gas, coke oven gas and blast furnace gas) and fuel used for heat production (3,3% of total amount fuel gas used in the UCPTE) has been substracted. Construction and demolition of a 100 MWe steam turbin power plant has been inventoried. Data concerning operation emissions, water use and wastes has been found in literature and in public statistics and has been adapted to the UCPTE fuel gas mix.

* Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.

System Boundaries

Nature Boundary	Used materials and energyware have been followed from extraction and processing of natural resources. Manufacturing processes for the use of recycled material are accounted for. Emissions from energyware use in manufacturing processes and transports (infrastructure and vehicle construction included) are considered as well as emissions from landfills (infrastructure included) where waste material is disposed of. Waste material supposed to be recycled are outputs of the system (i.e. those recycling processes are not included). Land is divided into two main groups - land and sea - which are subdivided into 4 categories each. Land Criterion Category Natural human impact not larger than other species' since the industrial revolution I Modified human impact larger than other species', low degree of cultivation II Cultivated human impact larger than other species', large degree of cultivation III Built upon dominated by buildings, roads, dams, mines etc. IV Category I is not used in the study. State of land before, during and after exploitation is of interest. If a piece of land is used again after some kind of exploitation it will either end up in the same category or in a higher one. ETH takes into account not only the land used during the technical lifetime of the studied system but also during the construction phase and during the time it takes to restore the land. They express use of land in the unit m2year which is different from comparable Swedish studies (m2). See times for restoration of land below: From category IV to category III 5 years From category III to category II 50 years From category II to category I 100 000 years (For uranium mines the restoration time to category II is 80'000 years due to elevated radiation caused by long-living radioactive compounds.) ETH's LCI-results comprise all parameters received during inventory and calculation, i.e. no selection has been made by ETH.
Time Boundary	Most of statistic figures used are from 1990 to 1994. For the calulation of the UCPTE gas electricity, fuel use in Europe of the year 1993 has been used. Data concerning material, chemical and energyware use are partly older. Figures concerning other fuel extraction and processing represent an average of the early nineties. Descriptions and figures of different technical processes come from literature, contractors, public and private institutions and describe the situation of the late eighties. Electricity used during the lifecycle has been assumed to be a mix based on the average generation in the UCPTE* countries between 1990-94 (to level off the large variations in hydro power production over the years). All processes, also those conducted in the past, have been assumed to use average technology of the early nineties. Different technical lifetimes/reference times for different parts and materials of the studied systems have been used as follows: Pipelines in the gas field 30 years Pipelines, long distance 50 years Pipelines, regional distribution 40 years Power plant 30 years * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Geographical Boundary	Most important supplier countries of natural gas in the UCPTE are the Netherlands (39%), the states of the former Soviet Union (22%), Algeria (11%), Norway (9%) and Germany (7%). The rest comes mainly from Italy, France and Denmark (these countries are not included in this study, approximated with German figures). Only the Swiss regional distribution net for natural gas has been inventoried as a whole. Resulting figures have been adapted to UCPTE* conditions. Processes conducted outside the UCPTE* region are supposed to be supplied with UCPTE* electricity. Data concerning the use of resources, emissions and waste in connection with manufacturing processes mainly originate from sources in Switzerland, Germany and other western European countries. * Union pour la coordination de la production et du transport de l'életricité, following

	countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Other Boundaries	Dismantling process of platforms is not included and the whole platform including drillhole mantelings and pipelines are assumed to be deposited, i.e. no recycling. Manufacture of needed chemicals in the processing plant for natural gas is neglected as well as the their transport. Manufacturing processes of components and machines have been approximated with 50% of the energyware used to produce contained materials. Energyware figures concerning material production come from literature and have assumed to be a mix of 10% UCPTE electricity, 45% oil and 45% natural gas. This approximation has been confirmed in more thorough calculations in ETH:s LCA for coal power. Big accidents occuring seldomly are not included.The threshold is fixed at 10 accidents per year if one energy carrier/system (e.g. oil) would cover the entire primary energy demand of the world.
Allocations	Allocation of pipelines to the produced amount of gas is difficult. The total gas distribution network has been inventoried and related to the total amount of transported gas in 1994 assuming that this is representative. Allocation between natural gas and crude oil when extracted together has been conducted according to the lower heating value. Allocation between electricity and heat in fuel gas power plants has been done according to exergy. The cutoff-method has been used for material use, i.e. 100% of the environmental load for virgin and recycled material used in the lifecycle is included whereas no environmental load has been considered for materials leaving the system to be recycled. Landfill processes and waste incineration, however, are included for waste arising during the lifecycle.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1985 to 1995
Data Type	Derived, unspecified
Represents	Average electricity generation with fuel gas in the UCTPE countries in the early nineties.
Method	The figures have been copied from the module ''Electricity from fuel gas power plant UCPTE-mix'' (Strom ab Brenngas-Kraftwerk UCPTE-Mix) in the Ökoinventare von Energiesystemen, ETH Zürich 1996.
Literature Reference	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz, Environmental Life-Cycle Inventories of Energy Systems An Environmental Database for the Accounting of Energy Consumption in Product Life-Cycle Assessment and the Comparative Assessment of Energy systems Prof. Dr. P. Suter, R. Frischknecht, et al Swiss Federal Institute of Technology, Zürich R. Dones, U. Gantner Paul Scherrer Institute, Villigen/Würenlingen
Notes	Multiple flows are reported for several emissions to air. This is because that in the original study emissions to air have been reported in three categories, indicated by one of the letters below following the substance name. - m = mobile (emissions from vehicles) - p = process (process specific emissions as for instance methane emissions during coal mining) - s = stationary (emissions from stationary combustion plants) This categorisation has however not been documented in this specification in the SPINE format.

About Inventory

Publication	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz. ETH, Eidgenössische Technische Hochschule, Zürich, Gruppe Energie - Stoffe - Umwelt (ESU), Paul Scherrer Institut, Villigen/Würenlingen, Sektion Ganzheitliche Systemanalysen Available on CD-ROM with full documentation (in German) at http://www. energieforschung.ch -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by (see also Notes): Rolf Frischknecht, ESU-services, Switzerland Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	Original study of ETH: LCA pra
General Purpose	The purpose of the ETH study was to examine a number of energy systems quantitatively and to the same extent with respect to environmental issues during their lifecycles. The results can be used in lifecycle assessments, as basis information in decisionmaking regarding environmental optimisation or in working with municipal energy plans.
Detailed Purpose	ETH:s aim was to describe the average situation in Europe concerning electricity generation with fuel gas (a mix of natural gas, coke oven gas and blast furnace gas). With the help of assumptions and simplifications following phases of the life cycle are described: exploration (on- and offshore) extraction (on- and offshore), processing, long-distance transports, distribution and power plant.
Commissioner	BEW, PSEL - Bundesamt für Energiewirtschaft, Projekt- und Studienfonds der Elektrizitätswirtschaft .
Practitioner	Rolf Frischknecht et al - ETH, Eidgenössische Technische Hochschule, Institut für Energietechnik, Zürich and Paul Scherrer Institut, Sektion Ganzheitliche Systemanalyse, Villingen/Würenlingen .
Reviewer	None, see further under notes -
Applicability	Reported figures are supposed to be representative for fuel gas (natural gas, coke oven gas and blast furnace gas) electricity generation in the UCPTE countries in 1994.
About Data	Reliability of data put into this lifecycle study: More reliable share of on- and offshore extraction amounts of flaring (allocation betw. oil and gas assumed) energyware consump. in extraction and processing phase constr. of extraction and processing plants transportation concerning construction aggregation to the UCPTE-mix for power plants fuel gas mix (natural, coke oven and blast furn. gas) conventional emissions from power plant Less reliable drilling during exploration and extraction amounts and concentrations in intraformation water processing of gas (except energyware) cleaning of trace elements in proc. plant area use gas leakage in the former Soviet Union lifetime of pipelines average gas flows in pipelines fuel chain of Algerian natural gas especially LNG route emissions of N2O, NMVOC, CO Material manufacturing processes have been inventoried with a low degree of exactitude (except for steel, cement, aluminium, copper, bitumen, and platinum group metals for which rather detailed LCI data are provided. Results are reported with three figures, but it is stated in the original source that this does not mean that accuracy is that high (Part III, p.16). For references and sources of reported figures see further under Function, Nature boundary, Geographical boundaries, Publication, Notes and General metadata.

Notes	Reviewer of this specification of metadata describing the ETH study has been: Dr. Rolf Frischknecht, ESU-services (earlier at ETH) - approval of Vattenfall's interpretation ot the documentation Ann-Christin Pålsson, CPM - review of documentation quality according to the CPM data documentation requirements. Project Management of the ETH study, 3rd edition: Professor, Dr. P. Suter and R. Frischknecht, ETH Editorial staff of the 1st edition: R. Frischknecht, P. Hofstetter, I. Knoepfel, M. Ménard, ETH R. SPINE LCI dataset: Gas-turbine power plant with support systems

Administrative	
Finished	Y
Date Completed	1996-12-01
Copyright	
Availability	Public

Technical System	
Name	Gas-turbine power plant with support systems
Functional Unit	Net production of 1 kWh electricity
Functional Unit Explanation	The emissions and use of resources and raw materials are associated with the production of 1 kWh electricity.
Process Type	Cradle to gate
Site	
Sector	Grid electricity and district heat
Owner	
Technical system description	The studied system include *fuel production and operation and maintenance of a gas-turbine power plant.* To represent the electricity production of Vattenfall in gas-turbine power plants, a prospected gas turbine power plant constructed and located in a similar way as the gas turbine power plant in Slite, Gotland is studied. The power plant is assumed to operate on fuel oil 1 (Eo1) produced from crude oil from the Norwegian continental-shelf. The fuel has a sulphur content of 0,1 %. Vattenfall:s gas turbine plants are used as reserve power and primarily at transient needs. Production of materials, chemicals and electricty and transports, used in association with the fuel chain and the operation and maintenance of the plant are included. *The fuel production* include drilling and extraction of crude oil, maintenance and reinvestments of the oil platforms, transport to the refinery in Mongstad, Norway, where the oil is refined to fuel oil 1 and transport from the refinery to the power plant. Gas turbines generally operates on gasoil (lighter fractions of diesel oil and fuel oil 1 (Eo1)) with strict requirement on low metal content. The fuel is stored in cylindrical oil cisterns. Gas turbines can also operate on kerosene.

	Technical data for the studied plant Annual time of use (recalculated as operation time at full effect) (hours): 50 Supplied fuel effect (MW): 444 Electricity effect (net) (MW): 120 Assumed life-time (years): 60 Electricity production (net) during 60 years (TWh): 0,0360

System Boundaries	
Nature Boundary	The analysis starts with *extraction of crude oil.* All emissions are considered equivalent, independent of where they take place (locally, regionally, globally; in densely populated areas or rural areas).
Time Boundary	The power plant are assumed to operate during 60 years.
Geographical Boundary	The power plant is located in a similar way as the power plant in Slite, Gotland. The fuel used in the plant are refined from crude oil from the Norwegian continental-shelf. The oil is transported by tanker to the refinery in Mongstad (Norway), and then as fuel oil 1 with tanker to the power plant.
Other Boundaries	The studied system includes *fuel production and operation and maintenance of a gas-turbine power plant.* Calculations of building and demolition of the plant has been performed but are not included in this system. ***Sub-systems included in the system:*** • Drilling and extraction of oil, and maintenance and reinvestments of the oil platforms. • Known use of chemicals are accounted for. In the cases where it was possible to obtain data, resource use and emissions for the manufacture are included. • Use of resources and emissions to air from production of the electricity that is used in the life cycles. • Production of oil for the studied manufacturing processes and transports • Transports and manufacture of materials for maintenance are included but neglected in the calculations, since they have a small contribution. • Transports in association with the operation of the power plant. ***Sub-systems excluded from the system:*** • No reinvestments are included since the plant only is used for reserve power. • Equipment after the power station transformer. • Prospecting for oil and building and demolition of plants and production platforms and tanker for transport from the oil field in Norway to Gotland. • Waste and rest products are transported to final waste. Operation and chemical and biological decomposing processes in the final waste have not been considered. • The risk of major accidents and rare breakdowns and environmental consequences from these • Work environment • Environmental loads caused by the operation personnel • Emissions at ordinary occurring operation disturbances have not been studied.

Allocations	The *50/50 method* has been applied throughout the calculations. The method is described in ''Nordic Guidelines on Life-Cycle Assessment'', Nord 1995:20, The Nordic Council, Stockholm. Crude oil for production of fuel to the plant are assumed to be extracted together with natural gas. Data were obtained from Kristin Keiserås Bakkane, Novatech a.s. ''Life Cycle Data for Norwegian Oil and Gas'', that were based on the production at Norwegian oil fields in 1991. An average value for the extracted energy oil (78,6%) and gas (21,3%) for the year in question were used. In reality the distribution between extracted energy for oil and gas respectively, varies. Data has been allocated according to the average value, *i.e. 78,6% of emissions and use of resources are allocated to the crude oil production.* Equipment, use of resources and emissions used only in association with the extraction of one energyware are allocated 100% to that. The oil is assumed to be refined in Mongstad, Norway. Data for production of fuel oil 1 have been obtained from Statoil. The allocation between the different products in the refinery are not known.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	
Data Type	Derived, unspecified
Represents	Average electricity generation with fuel gas in the UCTPE countries in the early nineties.
Method	An LCA calculation of fuel production and operation and maintenance for a gas-turbine power plant.
Literature Reference	Brännström-Norberg B-M., Dethlefsen U., Johansson R., Setterwall C., Tunbrant S.,''Livscykelanalys för Vattenfalls elproduktion - Sammanfattande rapport'', in Swedish, Vattenfall AB
Notes	The parameters that are presented are chosen because they have a general interest and because the basis for these parameters are relatively good. All values are reported with 3 figures. The data are however seldom that accurate.

About Inventory	
Publication	Brännström-Norberg B-M., Dethlefsen U., Johansson R., Setterwall C., Tunbrant S.,''Livscykelanalys för Vattenfalls elproduktion - Sammanfattande rapport'', Vattenfall AB Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology
Intended User	The data can be used as a basi
General Purpose	• The work with life-cycle analysis are expected to *contribute to a reinforcement and structuring* of the environmental work within Vattenfall, and a deeper knowledge on the use of resources and emissions to the environment. • An LCA can *facilitate a need for reliable data for electricity production.* Electricity is used in the manufacture of almost every product, and data from an LCA can be used when conducting an LCA on products. • An LCA can *facilitate a choice between different techniques* for future electricity production. • An LCA can also help to *choose the most effective alternatives* to reduce the consumption of resources and environmental influence of the current electricity production system. • It is also possible to *compare* the environmental load for different alternatives of electricity production.
Detailed Purpose	To obtain a *reliable basis* to be able to perform life-cycle analyses of different types of electricity use, and to identify opportunities for improvements in the existing system. To identify data gaps and areas where the knowledge are poor.
Commissioner	- Vattenfall Elproduktion .
Practitioner	- Vattenfall Energisystem AB: Britt-Marie Brännström-Norberg Ulrika Dethlefsen Roland Johansson Caroline Setterwall Sofie Tunbrant .
Reviewer	- Thomas Ekvall, Chalmers Industriteknik (CIT) Gunnar Lindfors, Institutet för Vatten- och Luftvårdsforskning (IVL) Göran Finnveden, Institutet för Vatten- och Luftvårdsforskning (IVL)
Applicability	The studied system includes fuel production and operation and maintenance of a gas-turbine power plant. The analysis are based on data from a plant that are chosen to make the analysis *representative* for the operation and maintenance of *Vattenfall:s gas-turbine power plants*. Vattenfall:s gas turbine plants are used as reserve power and primarily at transient needs. The data is reliable since a specific plant have been studied. The consequence is however that the result is primarily valid for the studied plant. Thoroughly reliable data for every power source, requires life cycle analyses for a large number of power plants for every power source. There are 12 gas turbine plants in Sweden. Transmission and distribution losses are not included. When the result is used to study different types of electricity use, these losses should be included. A rough estimate are that the distribution losses for a large industry customer are approximately 5% of the bought electricity, i.e. to obtain data for the use of electricity the data should be multiplied with 1,05. For an average household customer the transmission losses are approximately 10% of the bought electricity, i.e. the data should be multiplied with 1,10. The choice of *emission data* has a major influence on the result. This is determined at the permit consideration for a plant, and may vary between different plants and countries. The choice of combustion technique and fuel also influence the result. In recent years water injection have been introduced in some of Vattenfall:s gas turbines. Water injection reduces the NOx emissions but also the degree of efficiency for electricity production. Gas turbines can be operated on kerosene or fuel oil 1 (Eo1), where Eo1 oil gives higher emissions of sulphur. The calculated *emissions from Norwegian oil extraction*

are probably not representative for oil that will be extracted in a few years. The emissions of NO_x and CO_2 will be reduced. The emissions from the gas-turbines used for electricity production on the oil platforms will be reduced by installation of low-NO_x-burners. For some turbines the NO_x emissions are estimated to be reduced by 80%. To reduce CO_2 emissions, Norwegian authorities have introduced a CO_2-charge. Use of gas-turbines, with a higher degree of efficiency will reduce the CO_2-emissions. The new oil-field, Trollfältet, taken in use in 1995 will use electricity from the Norwegian power net, which will reduce local emissions on the platform.

The complete study include building, operation and maintenance, and demolition of the power plant and fuel production. When the data is used for energy production in a life cycle analysis of a product or a system, that do not require expansion of the electricity production system, it however reasonable only to include fuel production and operation and maintenance. The other phases of the life cycle are the same independent on the electricity production.

About Data

The studied plant is a *prospected gas turbine power plant fired with fuel oil 1*, produced from crude oil from the Norwegian continental-shelf. It is constructed and located in a similar way as the gas turbine power plant in Slite, Gotland.

Data for the use of resources and energy for operation of the power stations are specific for the studied plant. Relevant data for transports, extraction and production of metals and chemicals, and manufacture and work on important components were hard to obtain. Data from manufacturers and other reports and studies, primarily life cycle analyses have been used. Production of material and transports are considered with current technology. Swedish standard values have been used to calculate fuel use and emissions from transports. Transport distances are specific for the operation of the plant.

The parameters that are presented are chosen because they have a general interest and because the basis for these parameters are relatively good. All values are reported with 3 figures. The data are however seldom that accurate.

Data for *extraction of crude oil* were obtained from Kristin KeiserÕs Bakkane, Novatech a.s. "Life Cycle Data for Norwegian Oil and Gas", that were based on the production at Norwegian oil fields in 1991.

The following *emission factors* have been used to calculate the emissions from operation of the power plant. The emission factors are based on an average of the emissions from Vattenfall¦s existing gas-turbines.
NO_x: 220 mg/MJ fuel; 30,8 g/kWh electricity
SO_2: 48 mg/MJ fuel; 0,667 g/kWh electricity
CO: 77 mg/MJ fuel; 1,08 g/kWh electricity
Particles: 3,4 mg/MJ fuel; 0,047 g/kWh electricity
CO_2: 70400 mg/MJ fuel; 986 g/kWh electricity
HC: 4,0 mg/MJ fuel; 0,056 g/kWh electricity

For electricity used in the manufacture of materials and fuels, *average electricity* for the respective countries distributed on the different electricity production alternatives have been used. The following *degrees of efficiencies* have been used to calculate the fuel used in the electricity production. The values are standard values for existing power plants. New modern plants have often higher degrees of efficiencies. The values are calculated from the effective heat value in the used fuels and the energy content in the steam produced in a nuclear power plant.

- Coal condensing: 40%
- Oil condensing: 40%
- Natural gas condensing/combination: 40%
- Gas turbine: 25%
- Combined heat and power plant(irrespective of fuel) 30% (for electricity production)
  85% (total for electricity and heat production)
- Water power: are not recalculated, are accounted for as kWh electricity

	• Nuclear power: 33%, are however not recalculated, but accounted for as kWh electricity or gram natural uranium.

Technical system description	Polystyrene is a versatile polymer resin used in a wide range of applications - especially in the packaging industry. It is sold in the three main domains : crystal or general purpose polystyrene, high impactpolystyrene and expandable polystyrene. The production of styrene monomer can be thought of as replacing one of the hydrgen atoms in ethylene by a benzene ring (C6H6). The monomer is then polymerised in a manner similar to the polyethylene. In practise, the production route from crude oil and natural gas is as shown in figure 11. Crude oil refining produces a fraction known as naphta which contains a mixture of low molecular weight, saturated hydrocarbons of various composition. This is converted into smaller group of unsaturated hydrocarbons by cracking. The resulting mixture is then separated into its constituent components by distillation producing principally ethylene (C2H4), propylene (C3H6), mixed butenes of general formula C4H8 and a number of other compounds which find uses elsewhere in the petrochemical plant either as feedstocks or fuels. Although benzene is usually present in small quantities in crude oil, its direct extraction is usually uneconomic. Benzene can also be produced from naphtha by a process known as catalytic reforming. It is assumed that 50% is derived from each source.

About Inventory	
Publication	Eco profiles of the European plastics industry Report 4: Polystyrene (Second edition), 1997, APME Data documented by: Sophie Louis, Volvo Technical Development Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	APME's eco-profiles serve two
General Purpose	There is an increasing demand concerning LCA data. Following this trend, APME members in Western Europe wanted to provide public ''Cradle to the gate data'' concerning their product's life-cycle.
Detailed Purpose	The aim here is to provide ''cradle to gate'' data for the manufacturing of GPPS
Commissioner	- APME, Avenue E. Van Nieuwenhuyse 4 Box 3 B-1160 Brussels.
Practitioner	Boustead, Ian Dr - .
Reviewer	
Applicability	
About Data	Data for the production of general purpose polystyrene is based on the production characteristics of 15 polymerisation operations producing a total of 810 000 tonnes of GPPS.
Notes	

SPINE LCI dataset: Germany, electricity generation mix 1998

Administrative

Finished	Y
Date Completed	2001-01-31
Copyright	IEA
Availability	Public

Technical System

Name	Germany, electricity generation mix 1998
Functional Unit	Total electricity produced during 1998
Functional Unit Explanation	The electricity mix refer to the total amount of electricity generated by different power sources expressed in GWh during the year 1998.
Process Type	Unit operation
Site	Germany
Sector	Energyware
Owner	Germany
Technical system description	The generation of electricity with different power generating systems in Germany during the year 1998.

System Boundaries

Nature Boundary	Not applicable, since the data only refer to the electricity generation mix. The environmental load for generation of electricity is not included.
Time Boundary	The data refer to 1998.
Geographical Boundary	Only electricity produced in Australia is considered. Import or export of electricity is not included.
Other Boundaries	-
Allocations	Not applicable
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, statistics
Represents	Average electricity generation with fuel gas in the UCTPE countries in the early nineties.
Method	The data are collected from IEA Statistics.
Literature Reference	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8, page II.300.
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

About Inventory

Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998

SPINE LCI dataset: Glassworks

Administrative	
Finished	Y
Date Completed	1991-01-01
Copyright	
Availability	Public

Technical System	
Name	Glassworks
Functional Unit	1 kg
Functional Unit Explanation	1 kg of glass
Process Type	Gate to gate
Site	PLM AB, Limmared, Sweden
Sector	Consumer goods
Owner	PLM AB, Limmared, Sweden
Technical system description	PLM AB in Limmared produces both flint and amber glass. Glass is made mainly from the raw materials sand, soda, lime, dolomite and feldspar wich are fused at 1500-1600 degrees Celsius. It is a continous production process and the raw materials are constantly added, while the finished glass is taken out and cut into pieces suitable for the product which is shaped in the glass machine.

System Boundaries	
Nature Boundary	The observed nature boundary parameters are the emissions of NOx, SO2, CO2 and particulates to air and the emissions of suspended solids, oil and fat to water. Emissions from combustion (production) of electricity, LPG (Liquefied petrolium gas) and oil consumption are included. The emission factors for stationary installations of oil combustion is not included.
Time Boundary	
Geographical Boundary	The process takes place in Limmared, Sweden.
Other Boundaries	Observed parameters are electricity, LPG (Liquefied petrolium gas) and oil consumption. Further broken glass, sand, soda, lime, dolomite, feldspar and sodium sulphate come from the technosphere and glass go to the technosphere. No transports are included.

Allocations	
Systems Expansions	

Flow Data	
General Activity QMetaData	
Date Conceived	1991-01-01
Data Type	Derived, mixed
Represents	Average electricity generation with fuel gas in the UCTPE countries in the early nineties.
Method	Literature study of an official governmental report, where a literature study and personal communication have been put together (Baumann et al.) The calculations of energyware and CO2 emissions are made by those who transformed the data set into SPINE-format.
Literature Reference	Baumann H, Eriksson E, Rydberg T, Tillman A-M ''Life cycle analysis of selected packaging materials. Quantification of environmental loadings.'' Offprint from SOU 1991:77, Chalmers Industriteknik, Göteborg, Sweden The literature study in the literature mentioned above is done from the permission according to the Swedish Environmental Protection Law for PLM AB, Limmared at The Board of County in Älvsborg, The Environmental control unit 1990 and Sundström G, ''Energiförbrukning och miljöbelastning för distributionssystem för öl och läsk i Sverige'', Miljöbalans Gustav Sundström AB 1990. Personal communication contact is Eriksson K J, PLM AB, Limmared, Sweden and Nyström E, Svensk glasåtervinning AB, Sweden.
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

Flow Table and Specific Meta Data

QMetaData	***Direction***	***FlowType***	***Substance***	***Quantity***	***Min***	***Max***	***Unit***	***Environment***	***Geography***
Notes: There is 1-2% moisture content in broken glass.	Input	Refined resource	Broken glass	366			g	Technosphere	
	Input	Refined resource	Dolomite	58			g	Technosphere	
Notes: This electricity is used for fans, assembly lines etc.	Input	Refined resource	Electricity	0.4			MJ	Technosphere	
Notes: For the melting process oil and electricity are needed in an amount of 1050-1150 kcal/tonne molten glass, depending on capacity utilisation. 7-8% of this is electrical energy. The figures are valid for the mix of 50% broken glass and 50% virgin raw material. A 2% energy saving is achived per 10% broken glass addad.	Input	Refined resource	Energyware		1.05	1.15	kcal	Technosphere	
	Input	Refined resource	Feldspar	43			g	Technosphere	
	Input	Refined resource	Lime	83			g	Technosphere	
Notes: LPG (Liquefied petrolium gas) is used at this rate irrespective of the amount of broken glass added in the melting process.	Input	Refined resource	LPG	0.564			MJ	Technosphere	
Notes: It is 5% moisture content in sand.	Input	Refined resource	Sand	76			g	Technosphere	
Notes: Soda is represented by 50% natural soda from the US and 50% Solvay soda.	Input	Refined resource	Soda	136			g	Technosphere	
	Input	Refined resource	Sodium sulphate	4			g	Technosphere	
Method: Carbon dioxide emissions are caused by the burning of oil and gas and by the release of gas from the melt. CO2 emissions in the form of melting losses amounts to approx. 170 g CO2/kg virgin raw material. Glass is made mainly from the raw materials sand (76 g), soda (136 g), lime (83 g), dolomite (58 g) and feldspar (43 g). Thus, the total amount of virgin raw material that is needed to produce 1 kg glass is 396 g. The carbon dioxide emissions are 170 g * 0,396 = 67,32 g. Notes: Carbon dioxide emissions are caused by the burning of oil and gas and	Output	Emission	CO2	67.32			g	Air	

by the release of gas from the melt. CO2 emissions in the form of melting losses amounts to approx. 170 g CO2/kg virgin raw material. The carbon dioxide emissions are also dependent on the proportion of broken glass added, because the consumption of fuel varies according to this amount.									
	Output	Emission	NOx	2.69			g	Air	
	Output	Emission	Oil and fat	0.009			g	Water	
	Output	Emission	Particulates	0.26			g	Air	
	Output	Emission	SO2	1.01			g	Air	
	Output	Emission	Susp solids	0.018			g	Water	
	Output	Product	Glass	1			kg	Technosphere	

About Inventory

Publication	Baumann H, Eriksson E, Rydberg T, Tillman A-M ''Life cycle analysis of selected packaging materials. Quantification of environmental loadings.'' Offprint from SOU 1991:77, Chalmers Industriteknik, Göteborg, Sweden --- Data documented by: Maria Erixon and Sara Ågren, project employed at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Henrikke Baumann and Anne-Marie Tillman (responsible for the course material) and Ann-Christin Pålsson (responisble for classification of the dataset), Technical Environmental Planning, Chalmers University of Technology ---
Intended User	A Life Cycle Assessment practi
General Purpose	To investigate what energy needs and emissions that is connected with the production and use of packaging material.
Detailed Purpose	To calculate the energy need and emission for the following scenarios: (1) Glass produced from 100% virgin raw materials; waste to dump. (2) Glass produced from 30% virgin raw materials, that is 70% is recycled material; waste to dump. (3) Glass produced from 100% virgin raw materials, 97% is washed-up containers for recycling (thirteen times)
Commissioner	- Swedish commission of packaging.
Practitioner	Tillman, Anne-Marie - Technical Environmental Planning Chalmers University of Technology 412 96 Göteborg Sweden .
Reviewer	
Applicability	Glass containers can be refilled and this is done on a large scale in the case of beverage containers for beer, soft drinks and spirits. Glass can also be recovered from broken glass, wich is remelted. Uncoloured glass can only be made from uncoloured broken glass, while coloured glass can be produced from unsorted raw materials. --- The emission factors for stationary installations of oil combustion can be found under the activity ''Combustion of oil'' in this database.
About Data	It may be assumed that soda consist of 50% natural soda from the US and 50% Solvay soda. Melting losses occur in the form of carbon dioxide from lime and soda together with loss of water from sand and broken glass. There is 1-2% moisture content in broken glass and 5% moisture content in sand. For the melting process oil and electricity are needed in an amount of 1050-1150 kcal/tonne molten glass, depending on capacity utilisation. 7-8% of this is electrical energy. The figures are valid for the mix of 50% broken glass and 50% virgin raw material. A 2% energy saving is achived per 10% broken glass added. Irrespective of the amount of broken glass added, LPG is also used, plus electricity in general for fans, conveyor belts etc. Carbon dioxide emissions are caused by the burning of oil and gas and by the release of gas from the melt. CO2 emissions in the form of melting losses amounts to approx. 170 g CO2/kg virgin raw material. The carbon dioxide emissions are also dependent on the proportion of broken glass added, because the consumption of fuel varies according to this amount.

Publication	LCA of Building Frame Structures Environmental Impact over the Life Cycle of Wooden and Concrete frame; Björklund, Tillman; Report 1997:2; TEP; CTH; Göteborg; Sweden -- Data documented by: Maria Erixon, project employed for the database project at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Thomas Björklund, Technical Environmental Planning, Chalmers University of Technology --
Intended User	To make an LCA of building fra
General Purpose	Among others, to analyse and assess the environmental impact of structural wooden and concrete frames in buildings during the whole life cycle, by using the method of LCA as a tool.
Detailed Purpose	To calculate the environmental load of wooden frames

Commissioner	- Finncement Finland .
Practitioner	Björklund Thomas, Tillman Anne-Marie - Technical Environmental Planning, CTH 412 96 Göteborg Sweden.
Reviewer	
Applicability	The function of the technical system is not sufficently described.
About Data	The average values are calculated from the environmental declarations of three Swedish production plants: Martinson Trä KB, Moelven Töreboda Limträ AB, Långshytte Trävaru AB. In the inventory of glue, additives like catalyst are not included. Environmental load from irrigation of timber is not included, neither the package industry.
Notes	--- --- Changes made to the data set after publishing in SPINE@CPM--- >>> 12 June 2001 <<< Changes made by Ann-Christin Pålsson, based on the original report (Björklund et al.). Comments: - References to environmental declarations, that were used as basis for the data, is supplemented in Method and Notes in QMetaData. - A input flow of 'Feedstock energy' (18,2 MJ) in the flow table has been deleted due to that it represented the energy content of the product, and not a real physical flow. - A text in Applicability refererring to Trätek for further information about the data set has been deleted. - Flow type for Electricity and Diesel in the flow table have been changed from Natural resource to Refined resource.

SPINE LCI dataset: Grinding of bearing rollers

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System

Name	Grinding of bearing rollers
Functional Unit	One ground bearing roller: 9,2 kg
Functional Unit Explanation	One spherical roller bearing 232/530 consists of following components: 1. one inner ring 2. one outer ring 3. one guide ring 4. one brass cage 5. 36 bearing rollers (coated or non-coated) For the manufacturing of one bearing roller, one ground bearing roller is needed. The ground roller weighs 9,2 kg.
Process Type	Unit operation
Site	SKF Sverige AB415 50 GÖTEBORG
Sector	Materials and components
Owner	SKF Sverige AB415 50 GÖTEBORG
Technical system description	This activity is a subactivity of the system: ''Production of bearing rollers (à 9,2 kg)'' After the heat treatment the rollers are transported back to the E-factory and all sides of the rollers are ground and hand polished. This dataset includes the energy consumption for the grinding process of bearing rollers. The scrap from the grinding process is sent to Ovako Steel AB in Hofors by train. These activities are NOT included in this study, but in the complete data system: ''Production of bearing rollers à 9,2 kg)''. When the rollers have been hand polished they are ready for assembling and are mounted into the SKF spherical roller bearing 232/530.

System Boundaries

Nature Boundary	Emissions to air are not measured and could therefore not be reported in this study. Emissions to water and the use of cutting fluid at SKF, Göteborg, could according to allocation difficulties and lack of time not be calculated. The steel scrap from the grinding process at SKF, Göteborg, is sent to Ovako Steel in Hofors for recycling and is therefore not seen as waste, but a co-product to the technosphere. The grinding plates are not followed from the cradle and not to the grave because of lack of time. The inflow and outflow of grinding plates are therefore ending in the technosphere.
Time Boundary	The data was collected during the autumn 2002, and no changes in the procedure are planned for the nearest future.
Geographical Boundary	The process is site specific for SKF in Göteborg, Sweden.
Other Boundaries	The electricity production is NOT included in this dataset, but must be accounted for to obtain the complete environmental impact. The impact from the production and disposal of the cutting fluid is not included in this dataset, since no data was available. The grinding plates could not be traced back to the cradle, since it was too time consuming.
Allocations	Energy consumption depends on how long the rollers is processed in the different process equipment. This varies according to weight, but also according to size and desired properties of the final product.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	02-08-01 - 02-12-31
Data Type	Derived, mixed
Represents	Average electricity generation with fuel gas in the UCTPE countries in the early nineties.
Method	Data is gathered from interviews with Niclas Thim, SKF Large Bearings, Sweden.

SPINE LCI dataset: Grinding of dolomite

Administrative

Finished	Y
Date Completed	99-01-25
Copyright	
Availability	Public

Technical System

Name	Grinding of dolomite
Functional Unit	1 kg ground dolomite
Functional Unit Explanation	
Process Type	Gate to gate
Site	Hydro Agri AB Box 516 SE-261 24 Landskrona Sweden
Sector	Materials and components

Owner	Hydro Agri AB Box 516 SE-261 24 Landskrona Sweden
Technical system description	The grinding takes place at the plant in Landskrona. The supply dolomite has a content of 12,5 % Mg.

System Boundaries

Nature Boundary	The system only includes grinding of dolomite, i.e production of electricity and extraction of dolomite is not included in this dataset.
Time Boundary	The data are figures for production in 1997.
Geographical Boundary	Hydro Agri AB in Landskrona, Sweden.
Other Boundaries	Emissions and use of resources due to the production of electricity is not included in this datset.
Allocations	Not applicable.
Systems Expansions	Not applicable.

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	Average electricity generation with fuel gas in the UCTPE countries in the early nineties.
Method	An average value for emissions of particulates (dust) to air were given in mg/h and the assumed yearly operating time was 3000 h/year. Total emissions per year were then calculated and divided by total amounts of dolomite ground in 1997. Example: (35 400 mg particulates/h) * (3000 h/yr) / (34 000 ton dolomite/yr) = 3.12 g particulates/t dolomite Total amount of electricity consumed was divided by total amounts of dolomite ground in 1997. See also ''Specific QMetaData''.
Literature Reference	Miljörapport (official environmental report) 1997, Hydro Agri AB, Box 516, 261 24 Landskrona, Sweden. Personal communication: Ronnie Persson, Hydro Agri AB in Landskrona, tel: +46 418 76100.
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

Flow Table and Specific Meta Data

About Inventory

Publication	Davis J, Haglund C (1999). ''Life Cycle Inventory (LCI) of Fertiliser Production - Fertiliser Products Used in Sweden and Western Europe''. SIK report no. 654. The Swedish Institute for Food and Biotechnology (SIK). Gothenburg, Sweden. -- Data documented by: Jennifer Davis, SIK (The Swedish Institute for Food and Biotechnology). Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --

Intended User	The data are intended to be us
General Purpose	To generate an inventory for emissions and use of resources due to the production of fertilisers used in Sweden.
Detailed Purpose	The purpose was not to compare different fertilisers with each other but to generate a thorough inventory of emissions and use of resources due to the production of different mineral fertilisers used in Sweden. Grinding of dolomite is one process step in the line of production of calcium ammonium nitrate (CAN) produced in Landskrona. The data are intended to constitute a useful basis of input information in life cycle assessments of food production systems.
Commissioner	- SIK AB, The Swedish Institute for Food and Biotechnology Box 5401 SE-402 29 Gothenburg Sweden .
Practitioner	Davis, Jennifer and Caroline Haglund - SIK AB Box 5401 402 29 Gothenburg Sweden.
Reviewer	-
Applicability	The dataset is applicable for data on grinding of dolomite in Sweden. The dolomite is mixed with ammonium nitrate to produce calcium ammonium nitrate (CAN). The dataset is included in the aggregated datset for production of CAN at Hydro Agri AB in Landskrona (cradle to gate).
About Data	Data is collected from the official environmental report distributed by Hydro Agri AB in Landskrona and also with personal communication with people working there.
Notes	Internal review of the report was performed by: Olle Ramnäs, CTH (Chamers University of Technology), Berit Mattsson and Magnus Stadig, SIK (The Swedish Institute for Food and Biotechnology).

SPINE LCI dataset: Handpolishing of bearing rollers

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Handpolishing of bearing rollers
Functional Unit	One bearing roller: 9,2 kg
Functional Unit Explanation	One spherical roller bearing 232/530 consists of following components: 1. one inner ring 2. one outer ring 3. one guide ring 4. one brass cage 5. 36 rollers (coated or non-coated) The functional unit for this process is one bearing roller. Note however that the data only represent the last handpolishing step in the manufacturing process. For the complete system see the activity ''Production of bearing rollers (á 9,2 kg)'' in SPINE@CPM database.
Process Type	Unit operation
Site	SKF Sverige AB415 50 GÖTEBORG
Sector	Materials and components
Owner	SKF Sverige AB415 50 GÖTEBORG
Technical system description	This activity is a process step included in the system: ''Production of bearing rollers (à 9,2 kg)'' (can be found in the SPINE@CPM database) This activity represents the last process step for the manufacturing of bearing rollers at SKFs site in Göteborg, Sweden. The rollers are being polished by hand in order to get a smooth surface.

	The dataset include energy consumption for hand polishing and the amount of grinding paper used. The grinding paper used is bought from Slipnaxos AB in Västervik, where the production of the grinding paper takes place. The production of grinding paper could be approximated with the activity ''Production of Kraftliner'' from SPINE@CPM database. Neither Production of Kraftliner nor the transport from Västervik to Göteborg are included in this dataset, but the Production of Kraftliner is included though in the complete data system: ''Production of bearing rollers (à 9,2 kg)'' When the rollers have been hand polished they are ready for assembling and are mounted into the SKF spherical roller bearing 232/530.

System Boundaries

Nature Boundary	Emissions to air are not measured and could therefore not be reported in this study. Emissions to water and the use of cutting fluid at SKF, Göteborg, could according to allocation difficulties and lack of time not be calculated.
Time Boundary	The data was collected during the autumn 2002.
Geographical Boundary	The process is site specific for SKF in Göteborg, Sweden.
Other Boundaries	The electricity production is NOT included in this dataset, but must be accounted for to get the complete environmental impact. The impact from the production and disposal of the cutting fluid is not included in this dataset, since no data was available. The grinding paper is not followed from the cradle but must be taken into account for the complete environmental impact. The production of grinding paper could be approximated with the activity ''Production of Kraftliner'' from SPINE@CPM database.
Allocations	Energy consumption depends on how long the rollers is processed in the different process equipment. This varies according to weight, but also according to size and desired properties of the final product.

SPINE LCI dataset: Heating of ingot at the rolling mill

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Heating of ingot at the rolling mill
Functional Unit	One ton of heated ingot
Functional Unit Explanation	The heated ingot will be further processed into bearing rings, used in SKF spherical roller bearing 232/530.
Process Type	Unit operation
Site	Ovako Steel AB SE-813 82 Hofors
Sector	Materials and components
Owner	Ovako Steel AB SE-813 82 Hofors
Technical system description	This activity is a process step in the whole system ''Production of bearing rings'', this activity is available in the SPINE@CPM database. Heating of ingot at the rolling mill: At the rolling mill at Ovako Steel in Hofors the ingots are rolled into billets. The ingots are first heated in a soaking pit to the proper rolling temperature. When the ingot has been rolled in the first stand of rolls it is transported to the oxygen-scarfing machine where surface defects are removed from the billet. The billet rolling is then continued in rolling stand 2 and 3. Depending on what will become of the ingot it is rolled to round or square billets. Finally the billets are inspected and surface defects, if any, are removed by grinding. IN this specific case the ingot is only heated in the soaking pit at the rolling mill. Instead of rolling in the rolling stands the ingot is transported to Scana Steel AB in Söderfors for forging into bars. (the transport from Hofors to Söderfors is NOT included in this dataset)

System Boundaries	
Nature Boundary	Emission to air and water are included. Emissions to soil are not known. The water recipient is Hoån, Sweden.
Time Boundary	All data refers to year 1999. No changes are planned for the nearest future.
Geographical Boundary	The rolling mill is located at Ovako Steel AB in Hofors,Sweden.

Other Boundaries	Production of light and heavy fuel oil is NOT included but must be followed from the cradle. Production of LPG is not included but must be followed from the cradle. No transport is included.
Allocations	Allocation have been made according to weight.
Systems Expansions	Not applicable

SPINE LCI dataset: Heating of smelt iron in a holding furnace

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Heating of smelt iron in a holding furnace
Functional Unit	6,59 kg heated smelt iron
Functional Unit Explanation	6,59 kg smelt iron is used to produce one bearing housing, SNL 511-609, at SKF Mekan AB in Katrineholm. This activity is also included in the production of guide rings. The dataset is used unchanged for our specific case, and thus the functional unit is 6,59 kg smelt iron. The figure 6,59 has nothing to do with guide rings as such.
Process Type	Unit operation
Site	SKF Mekan ABBox 89 641 21 Katrineholm
Sector	Materials and components
Owner	SKF Mekan ABBox 89 641 21 Katrineholm
Technical system description	This activity describes a process step included in the system ''Production of guide rings used for spherical roller bearings'', also available in the SPINE@CPM database. The guide ring is manufactured at SKF Mekan AB in Katrineholm and the process consists of several steps. (See the activity ''Production of guide rings used for spherical roller bearings'' for details.) The guide ring will finally be mounted into the SKF Spherical Roller Bearing 232/530. The function of the guide ring is to assure that the rollers stay in the raceways of the bearing.

	After the smelting process, the smelt is transported in a ladle to the holding furnace to keep it heated. This activity describes the energy consumption for the heating of the smelt iron in the holding furnace. The production of electricity is NOT included in this dataset, bust must be followed from the cradle in order to obtain the total environmental impact. Data is taken from an earlier LCA study of the bearing housing SNL 511-609: Rasmus Beckman and Henrik Olsson; Vilken miljöpåverkan uppstår vid tillverkningen av ett lagerhus?; Master Thesis at Kalmars University; August 2002.

System Boundaries

Nature Boundary	No emissions to air and water are known. The dataset is only describing the electricity consumption for the furnace.
Time Boundary	The data was collected during the autumn 2002 and no changes in the procedure are planned for the nearest future.
Geographical Boundary	The process takes place at SKF Mekan AB in Katrineholm, Sweden
Other Boundaries	The production of electricity is NOT included in this dataset, bust must be followed from the cradle in order to obtain the total environmental impact.
Allocations	Allocations were made according to weight
Systems Expansions	Not Applicable

SPINE LCI dataset: Heavy truck with international semitrailer, max 40 tonnes, future

Administrative

Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System

Name	Heavy truck with international semitrailer, max 40 tonnes, future
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is representative for Swedish domestic traffic if *empty trips are not included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of a diesel driven heavy truck with international semitrailer with engine representing best available technology (proposed Euro 3 environmental standard) with oxidation filter and catalytic control. The towcar for the equipage is a truck, max 24 tonnes. The equipage is new and not frequently used in Swedish domestic traffic. Maximum gross weight: 40 tonnes. Kerb weight: 22 tonnes. Available loading capacity with regard to weight: 18 tonnes.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents best available technology, not yet in regular use.
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle

	Excluded subsystems -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	Average electricity generation with fuel gas in the UCTPE countries in the early nineties.
Method	The emissions were calculated using emission factors obtained by the a new test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level. See specific QMetaData for each flow.
Literature Reference	Rasmus Beckman and Henrik Olsson; Vilken miljöpåverkan uppstår vid tillverkningen av ett lagerhus?; Master Thesis at Kalmars University; August 2002.
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

Date concieved: 1997-01-01 Data type: Unspecified, expert outspoke Method: The emission per tonkm was calculated from the fuel consumption using the sulphur content in the diesel ***The following data was used in the calculations:*** *Assumptions given by the Swedish Road Haulage Association:* -Average fuel consumption: 0,38 l/km. -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1 given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm See QMetaData for the Diesel flow for further information	Output	Emission	SO2	0.00044			g	Air	

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Michael Björkman, BTL (Bilspedition Transportation and Logistics), contact person for road transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport

	companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Björkman, Michael - BTL (Bilspedition Transportation and Logistics), 412 97 Göteborg .

Applicability	The ambition with the data was to get a picture of future energy use and emissions. The data represents best available technology not yet in use.
About Data	The data is based on tests on the engine performed in a laboratory according to a new test cycle (proposed for standardisation). This means that several parameters that influence the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially.
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Heavy truck with international semitrailer, max 40 tonnes, manufactured after 1996 [Euro 2]

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Heavy truck with international semitrailer, max 40 tonnes, manufactured after 1996 [Euro 2]
Functional Unit	1 tonkm, 70 %

Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is representative for Swedish domestic traffic if *empty trips are not included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of a diesel driven heavy truck with international semitrailer with engine manufactured after 1996 (Euro 2 environmental standard). The towcar for the equipage is a truck, max 24 tonnes. The equipage is new and not frequently used in Swedish domestic traffic. Maximum gross weight: 40 tonnes. Kerb weight: 22 tonnes. Available loading capacity with regard to weight: 18 tonnes.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents trucks with engine manufactured after 1996 (Euro 2)
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	Average electricity generation with fuel gas in the UCTPE countries in the early nineties.
Method	The emissions were calculated using emission factors obtained by the ECE R49 test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level (see specific QMetaData for a description on methods used for each flow). The *quantity value for the energy use* refer to average fuel consumption, *the maximum and minimum value* refer to changes in the efficiency of the engine due to degeneration. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, the quantity value* refer to an average engine guaranteed by Volvo Truck Corporation, the *maximum value* refer to an engine run 500 000 km. No minimum value was given.
Literature Reference	Rasmus Beckman and Henrik Olsson; Vilken miljöpåverkan uppstår vid tillverkningen av ett lagerhus?; Master Thesis at Kalmars University; August 2002.
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

Reviewer	
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles --*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. --*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited --*Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used for transportation in Sweden:*** --*Truck max 3,5 tonnes* is mainly used for transportation of parcels. --*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. --*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. --*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. --*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. --*Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***The Swedish fleet*** The data for different age categories of vehicles (before 92, 1992-1995, after 96) may be used to calculate average energy use and emissions for a specific fleet or the average Swedish fleet of vehicles regarding age distribution. In Sweden, 1996 the following shares of transportation work was carried out by the different age categories: After 1996: 10 % 95-92: 33% Before 1992 52 %

	The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.
About Data	Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years. The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions. A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute. The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

	Output	Cargo	Cargo	1			tonne	Technosphere	
Method: See QMetaData for NOx	Output	Emission	CO	0.17		1.4	g	Air	
Date concieved: 1997-01-01 Data type: Derived, unspecified Method: The emission per tonkm was calculated from the fuel consumption using the carbon content in the diesel. ***The following data was used in the calculations:*** *Assumptions given by the Swedish Road Haulage Association:* -Average fuel consumption: 0,38 l/km. -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1 given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm -CO2 emission: 73 g/MJ fuel See QMetaData for the Diesel flow for further information	Output	Emission	CO2	77	77	78	g	Air	
Method: See QMetaData for NOx	Output	Emission	HC	0.17		0.29	g	Air	
Date concieved: 1997-01-01 Data type: Derived, unspecified Method: The emissions per tonkm were calculated using emission factors (g/kWh) obtained by a standardised test cycle, ECE R49 on the engine, where kWh refers to mechanical work done by the engine. The emissions per tonkm were calculated using emission factors obtained by a standardised test cycle, ECE R49 on the engine. The emission factors are given in	Output	Emission	NOx	1.3	1	1.6	g	Air	

g/kWh, where kWh refers to mechanical work done by the engine. The quantity value refer to an average engine guaranteed by Volvo Truck Corporation, the maximum value refer to voluntary European emission regulations for diesel engines before 1992. No minimum value was given. *The following formula was used to calculate the emissions per tonkm:* (Average fuel consumption [l/km]*thermal value[kWh (fuel)/l]*efficiency [kWh(engine)/kWh(fuel)]*emission factor [g/kWh(engine)])/ (loading capacity [tonne]*utilisation level) ***The following data was used in the calculations:*** *Assumptions given by the Swedish Road Haulage Association:* -Average fuel consumption: 0,38 l/km. -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1 given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm *The emission factors were: Quantity value, i.e. average engine:*: -NOx 11 g/kWh -HC 1,5 g/kWh -CO 1,5 g/kWh -Particles 0,4 g/kWh (estimated) -Degree of efficiency on the engine:39 % (assumed) The data was supplied by the Volvo Truck Corporation. *Maximum value, i.e. voluntary European emission regulations:* -NOx 14 g/kWh -HC 2,5 g/kWh -CO 12 g/kWh -Particles - g/kWh (not given) -Degree of efficiency on the engine: 39 %. No minimum value was given. *The ECE R49 is a steady state cycle for heavy duty truck engines*. Consists of a sequence of 13 constant engine speed and load modes. Emissions are analysed for each test mode. Then the overall emission result is calculated as a (weighted) average from all test modes. The cycle is characterised by high average engine load and high exhaust gas temperature. Notes: Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially.									
Method: See QMetaData for NOx	Output	Emission	Particles	0.046			g	Air	
Date concieved: 1997-01-01 Data type: Unspecified, expert outspoke Method: The emission per tonkm was calculated from the fuel consumption using the sulphur content in the diesel ***The following data was used in the calculations:*** *Assumptions given by the Swedish Road Haulage Association:* -Average fuel consumption: 0,38 l/km. -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1 given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm See QMetaData for the Diesel flow for further information Notes: Since exhaust emissions	Output	Emission	SO2	0.00049	0.00048	0.0005	g	Air	

depend on the engine speed and load conditions, the emissions in actual operation may vary substantially.									

About Inventory	
Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Michael Björkman, BTL (Bilspedition Transportation and Logistics), contact person for road transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Björkman, Michael - BTL (Bilspedition Transportation and Logistics), 412 97 Göteborg .
Reviewer	
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles --*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. --*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited --*Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used for transportation in Sweden:*** --*Truck max 3,5 tonnes* is mainly used for transportation of parcels. --*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. --*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. --*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. --*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in

	Finland. --*Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***The Swedish fleet*** The data for different age categories of vehicles (before 92, 1992-1995, after 96) may be used to calculate average energy use and emissions for a specific fleet or the average Swedish fleet of vehicles regarding age distribution. In Sweden, 1996 the following shares of transportation work was carried out by the different age categories: After 1996: 10 % 95-92: 33% Before 1992 52 % The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.
About Data	Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years. The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions. A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute. The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for

	road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Heavy truck with international semitrailer, max 40 tonnes, manufactured between 1992 and 1995[Euro1]

Administrative

Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System

Name	Heavy truck with international semitrailer, max 40 tonnes, manufactured between 1992 and 1995[Euro1]
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is representative for Swedish domestic traffic if *empty trips are not included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of a diesel driven heavy truck with international semitrailer with engine manufactured between 1992 and 1995 (Euro 1 environmental standard). The towcar for the equipage is a truck, max 24 tonnes. The equipage is new and not frequently used in Swedish domestic traffic. Maximum gross weight of the equipage: 40 tonnes. Kerb weight: 22 tonnes. Available loading capacity with regard to weight: 18 tonnes.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents trucks with engine manufactured between 1992 and 1995
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc.

	-Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	Average electricity generation with fuel gas in the UCTPE countries in the early nineties.
Method	The emissions were calculated using emission factors obtained by the ECE R49 test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level (see specific QMetaData for a description on methods used for each flow). The *quantity value for the energy use* refer to average fuel consumption, *the maximum and minimum value* refer to changes in the efficiency of the engine due to degeneration. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, the quantity value* refer to an average engine guaranteed by Volvo Truck Corporation and the *maximum value* refer to the emission regulations for diesel engines according to the emission standard Euro I.
Literature Reference	Rasmus Beckman and Henrik Olsson; Vilken miljöpåverkan uppstår vid tillverkningen av ett lagerhus?; Master Thesis at Kalmars University; August 2002.
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

About Inventory	
Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Michael Björkman, BTL (Bilspedition Transportation and Logistics), contact person for road transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Björkman, Michael - BTL (Bilspedition Transportation and Logistics), 412 97 Göteborg .
Reviewer	
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal

The collection and distribution routes are generally performed by smaller vehicles

--*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport.
--*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited
--*Parcel goods (<100 kg)* are normally handled in small vehicles

The following vehicles and equipages are used for transportation in Sweden:
--*Truck max 3,5 tonnes* is mainly used for transportation of parcels.
--*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic.
--*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic.
--*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods.
--*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland.
--*Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic.

Utilisation level
The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low.

The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden):
-excavated materials and round timber - 50%
-manufactured products (wholesale goods) - slightly more than 20%
-provisions and animal forage - approx. 15%
-mixed cargo (general goods) approx - 10 %.

The Swedish fleet
The data for different age categories of vehicles (before 92, 1992-1995, after 96) may be used to calculate average energy use and emissions for a specific fleet or the average Swedish fleet of vehicles regarding age distribution. In Sweden, 1996 the following shares of transportation work was carried out by the different age categories:
After 1996: 10 %
95-92: 33%
Before 1992 52 %
The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes.

Bulky goods
The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.

Fuel
The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions.

Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions.

International road transports
The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.

About Data

Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc.

Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years.

The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle

	that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions. A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute. The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Heavy truck with one trailer, long distance, Euro 0

Administrative	
Finished	Y
Date Completed	1998 - 08
Copyright	NTM
Availability	Public

Technical System	
Name	Heavy truck with one trailer, long distance, Euro 0
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is considered to be representative for Swedish domestic long-distance traffic if *empty trips are not included.*
Process Type	Gate to gate
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of heavy truck with one trailer for long distance transports, approximately 18 m long with a curb weight of 40 tons and a maximum load of 26 tons. Fuel: diesel, MK 1 (sulphurous content: 2 ppm). Fuel consumption: high 3.8 l/10 km, medium 3.5 l/10 km, low 3.2 l/10 km. Engine type: Euro 0 (1987-1992). Utilisation level: 70% by weight.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	Data are valid for trucks produced 1987 - 1992
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1998 - 08
Data Type	Derived, unspecified
Represents	NTM
Method	Data have been put together for NTM by a group of manufacturers and hauliers, i.e. Volvo, Scania, BTL, ASG, Swedish Hauliers Assosiation. Data are presented in relation to the transport work, in g/tonkm. The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic and 70 % for long distance transport with heavy trucks. The utilisation level is based on the load carrying weight, i.e. the weight on which the customer price is based. This means that bulky cargo is multiplied with a factor in order to compensate for taking up volume. The average break-point density is 275 kg/m3. Energy use and emissions per tonkm with a truck should be based on the load carrying weight. The *quantity value for the energy use* refer to average fuel consumption, the *maximum and minimum value* refer to changes in the fuel consumption due to degeneration, driving behavour etc.. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, The emission data have been produced through simulations conducted by Volvo Trucks and Scania in 1997. The simulations were based on certification values for engines and fuel consumption under actual operation for Swedish conditions. For medium and light lorries, the emission values have been obtained from certification values for new engines that are operated in accordance with established operating cycles, e.g. ECR-49 (IVL and Mercedes). Emissions data related to fuel consumption Emission factors (g/liter) Euro 0 Euro 1 Euro 2 Law from: 1980 1990 1993 1996 NOx 52+/- 5 44 27 23 HC 6+/- 2 2.1 1.8 1.3 PM 3+/- 2 1 0.5 0.35 CO 8+/- 3 3.7 3.4 2.5 This shows emissions factors in g/l for heavy lorries. With fuel consumption as a basis, it is possible to calculate the emissions. The data on emissions are based on measurements in accordance with applicable standards for certification. liters/100 km Empty Full load Distribution lorry (Payload 8.5 ton) 20-25 25-30 Med.-size lorry (Payload 14 ton) 25-30 30-40 Heavy lorry w trailer (Payl. 26 ton) 22-27 32-38 Heavy lorry w 2 trail. (Payl. 40 ton) 28-33 43-55*
Literature Reference	Rasmus Beckman and Henrik Olsson; Vilken miljöpåverkan uppstår vid tillverkningen av ett lagerhus?; Master Thesis at Kalmars University; August 2002.
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

About Inventory	
Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	- Swedish haulages and transport companies .
Reviewer	None, to be reviewed. -
Applicability	The data should not be used for any detailed study of transport systems. More detailed information is needed in order to carry out such studies, e.g. regarding the vehicle -type -age and performance, fuel type, the nature of the goods, the utilisation level etc. For a specific transport, the company carrying out the transport should be contacted in order to get information on how the goods are handled and how the transport is carried out. Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred. The standard values presented in this activity should not be used if specific information on the fuel consumption for the transport is availiable. In this case, the fuel consumption should instead be used as a basis to calculate the emissions from the transport. See General QMetaData for emission factors that can be used to calculate emissions per litre fuel used. The age categories of the vehicles compiled in the work are: Older than 1990, Euro 0: Introduced 1987, law from 1990 Euro 1: Introduced 1991, law from 1993 Euro 2: Introduced 1993, law from 1996 However, in order to improve the accuracy of the calculations, the user ought to know the Euro-class (emission standards) of the vehicle, rather than to base the calculations on the age of the vehicle.

Handling of goods
The data presented by NTM is representative for a terminal based transport system. The vehicles can be used in different ways, primarily altering the degree of utilisation. Several other types of road based cargo transport systems is not well described by the data (e.g. oil and excavated materials)
Terminal based road transports generally consists of 1-3 parts:
1. Collection of the goods to terminal
2. Long-distance transport between terminals
3. Distribution of the goods from terminal
The collection and distribution routes are generally performed by smaller vehicles while the inter-terminal traffic is operated by larger units, typically with a higher degree of utilisation.

--*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport.
--*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited
--*Parcel goods (<100 kg)* are normally handled in small vehicles

The following vehicles and equipages are used in terminal based transport systems in Sweden:
--*Parcel truck/van, max 3,5 tonnes* is mainly used for transportation of parcels.
--*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic.
--*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic.
--*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods.
--*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland.
--*Truck with semi-trailer, max 42 tonnes* is used for international long-distance traffic.

Utilisation level
The data is only applicable for an utilisation level of 70 % which is considered representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip, due to specialised vehicles). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than smaller firms of haulage. The utilisation of company internal vehicles is generally low.

The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden):
-excavated materials and round timber - 50%
-manufactured products (wholesale goods) - slightly more than 20%
-provisions and animal forage - approx. 15%
-mixed cargo (general goods) approx - 10 %.

Bulky goods
The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.

Fuel
The fuel used is diesel environmental class 1, except for petrol driven delivery vans who are assumed to use standard unleaded petrol. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (> 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions.

Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the data. NGM propose that data from Blinge et. al (Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997) should be used. This study is based on best available technology and Swedish conditions which is likely to yield a low figure.

International road transports
The data may be used for international transport if the data is recalculated for diesel environmental class 3. This will alter both the SOx emission and the regulated engine emissions. Generally the fleets in western Europe is composed of newer vehicles than in Sweden. The utilisation of the vehicles may also vary in different countries.

About Data

The calculations of data on heavy trucks are based on the fuel consumption of the vehicle. The fuel consumption data have been obtained by simulations of heavy vehicles in traffic under Swedish conditions. These simulations were made by Volvo Trucks and Scania, especially for NTM. The data on emissions are based on measurements in accordance with applicable standards for certification.

Notes	The person stated as ''Practitioner'' is the contact person for the data for truck transportation in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

Flow Data

General Activity QMetaData

Date Conceived	1998 - 08
Data Type	Derived, unspecified
Represents	NTM
Method	Data have been put together for NTM by a group of manufacturers and hauliers, i.e. Volvo, Scania, BTL, ASG, Swedish Hauliers Assosiation. Data are presented in relation to the transport work, in g/tonkm. The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic and 70 % for long distance transport with heavy trucks. The utilisation level is based on the load carrying weight, i.e. the weight on which the customer price is based. This means that bulky cargo is multiplied with a factor in order to compensate for taking up volume. The average break-point density is 275 kg/m3. Energy use and emissions per tonkm with a truck should be based on the load carrying weight. The *quantity value for the energy use* refer to average fuel consumption, the *maximum and minimum value* refer to changes in the fuel consumption due to degeneration, driving behavour etc.. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, The emission data have been produced through simulations conducted by Volvo Trucks and Scania in 1997. The simulations were based on certification values for engines and fuel consumption under*

	actual operation for Swedish conditions. For medium and light lorries, the emission values have been obtained from certification values for new engines that are operated in accordance with established operating cycles, e.g. ECR-49 (IVL and Mercedes). Emissions data related to fuel consumption Emission factors (g/liter) Euro 0 Euro 1 Euro 2 Law from: 1980 1990 1993 1996 NOx 52+/- 5 44 27 23 HC 6+/- 2 2.1 1.8 1.3 PM 3+/- 2 1 0.5 0.35 CO 8+/- 3 3.7 3.4 2.5 This shows emissions factors in g/l for heavy lorries. With fuel consumption as a basis, it is possible to calculate the emissions. The data on emissions are based on measurements in accordance with applicable standards for certification. liters/100 km Empty Full load Distribution lorry (Payload 8.5 ton) 20-25 25-30 Med.-size lorry (Payload 14 ton) 25-30 30-40 Heavy lorry w trailer (Payl. 26 ton) 22-27 32-38 Heavy lorry w 2 trail. (Payl. 40 ton) 28-33 43-55
Literature Reference	
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

About Inventory

Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	- Swedish haulages and transport companies .

Reviewer	None, to be reviewed. -
Applicability	The data should not be used for any detailed study of transport systems. More detailed information is needed in order to carry out such studies, e.g. regarding the vehicle -type -age and performance, fuel type, the nature of the goods, the utilisation level etc. For a specific transport, the company carrying out the transport should be contacted in order to get information on how the goods are handled and how the transport is carried out. Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred. The standard values presented in this activity should not be used if specific information on the fuel consumption for the transport is availiable. In this case, the fuel consumption should instead be used as a basis to calculate the emissions from the transport. See General QMetaData for emission factors that can be used to calculate emissions per litre fuel used. The age categories of the vehicles compiled in the work are: Older than 1990, Euro 0: Introduced 1987, law from 1990 Euro 1: Introduced 1991, law from 1993 Euro 2: Introduced 1993, law from 1996 However, in order to improve the accuracy of the calculations, the user ought to know the Euro-class (emission standards) of the vehicle, rather than to base the calculations on the age of the vehicle. ***Handling of goods*** The data presented by NTM is representative for a terminal based transport system. The vehicles can be used in different ways, primarily altering the degree of utilisation. Several other types of road based cargo transport systems is not well described by the data (e.g. oil and excavated materials) Terminal based road transports generally consists of 1-3 parts: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles while the inter-terminal traffic is operated by larger units, typically with a higher degree of utilisation. *--Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. *--General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited *--Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used in terminal based transport systems in Sweden:*** *--Parcel truck/van, max 3,5 tonnes* is mainly used for transportation of parcels. *--Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. *--Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. *--Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. *--Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. *--Truck with semi-trailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for an utilisation level of 70 % which is considered representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip, due to specialised vehicles). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than smaller firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally

	accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1, except for petrol driven delivery vans who are assumed to use standard unleaded petrol. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (> 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the data. NGM propose that data from Blinge et. al (Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997) should be used. This study is based on best available technology and Swedish conditions which is likely to yield a low figure. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. This will alter both the SOx emission and the regulated engine emissions. Generally the fleets in western Europe is composed of newer vehicles than in Sweden. The utilisation of the vehicles may also vary in different countries.
About Data	The calculations of data on heavy trucks are based on the fuel consumption of the vehicle. The fuel consumption data have been obtained by simulations of heavy vehicles in traffic under Swedish conditions. These simulations were made by Volvo Trucks and Scania, especially for NTM. The data on emissions are based on measurements in accordance with applicable standards for certification.
Notes	The person stated as ''Practitioner'' is the contact person for the data for truck transportation in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: Heavy truck with one trailer, long distance, made before 1990

Administrative	
Finished	Y
Date Completed	1998 - 08
Copyright	NTM
Availability	Public

Technical System	
Name	Heavy truck with one trailer, long distance, made before 1990
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is considered to be representative for Swedish domestic long-distance traffic if *empty trips are not included.*
Process Type	Gate to gate
Site	Sweden
Sector	Land transport
Owner	Sweden

Technical system description	Operation of heavy truck with one trailer for long distance transports, approximately 18 m long with a curb weight of 40 tons and a maximum load of 26 tons. Fuel: diesel, MK 1 (sulphurous content: 2 ppm). Fuel consumption: high 3.8 l/10 km, medium 3.5 l/10 km, low 3.2 l/10 km. Engine type: made before 1990. Utilisation level: 70% by weight.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO_2 -tax regulated CO_2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	Data are valid for trucks produced before 1990
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests

Applicability	The data should not be used for any detailed study of transport systems. More detailed information is needed in order to carry out such studies, e.g. regarding the vehicle -type -age and performance, fuel type, the nature of the goods, the utilisation level etc. For a specific transport, the company carrying out the transport should be contacted in order to get information on how the goods are handled and how the transport is carried out. Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred. The standard values presented in this activity should not be used if specific information on

the fuel consumption for the transport is availiable. In this case, the fuel consumption should instead be used as a basis to calculate the emissions from the transport. See General QMetaData for emission factors that can be used to calculate emissions per litre fuel used.

The age categories of the vehicles compiled in the work are:
Older than 1990,
Euro 0: Introduced 1987, law from 1990
Euro 1: Introduced 1991, law from 1993
Euro 2: Introduced 1993, law from 1996
However, in order to improve the accuracy of the calculations, the user ought to know the Euro-class (emission standards) of the vehicle, rather than to base the calculations on the age of the vehicle.

Handling of goods
The data presented by NTM is representative for a terminal based transport system. The vehicles can be used in different ways, primarily altering the degree of utilisation. Several other types of road based cargo transport systems is not well described by the data (e.g. oil and excavated materials)
Terminal based road transports generally consists of 1-3 parts:
1. Collection of the goods to terminal
2. Long-distance transport between terminals
3. Distribution of the goods from terminal
The collection and distribution routes are generally performed by smaller vehicles while the inter-terminal traffic is operated by larger units, typically with a higher degree of utilisation.

--Wholesale goods (>1000 kg) are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport.
--General goods (100-1000 kg) are generally handled via terminal. The goods may be both weight and volume limited
--Parcel goods (<100 kg) are normally handled in small vehicles

The following vehicles and equipages are used in terminal based transport systems in Sweden:
--Parcel truck/van, max 3,5 tonnes is mainly used for transportation of parcels.
--Light truck, max 8 tonnes is used for local distribution, mainly in city traffic.
--Truck, max 18 tonnes is used for district distribution and local distribution in city traffic.
--Truck, max 24 tonnes is mainly used for transportation of general (styckegods) and wholesale (partigods) goods.
--Heavy truck with trailer, max 60 tonnes is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland.
--Truck with semi-trailer, max 42 tonnes is used for international long-distance traffic.

Utilisation level
The data is only applicable for an utilisation level of 70 % which is considered representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip, due to specialised vehicles). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than smaller firms of haulage. The utilisation of company internal vehicles is generally low.

The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden):
-excavated materials and round timber - 50%
-manufactured products (wholesale goods) - slightly more than 20%
-provisions and animal forage - approx. 15%
-mixed cargo (general goods) approx - 10 %.

Bulky goods
The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.

Fuel
The fuel used is diesel environmental class 1, except for petrol driven delivery vans who are assumed to use standard unleaded petrol. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (> 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions.

Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the data. NGM propose that data from Blinge et. al (Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997) should be used. This study is based on best available technology and Swedish conditions which is likely to yield a low figure.

	International road transports The data may be used for international transport if the data is recalculated for diesel environmental class 3. This will alter both the SOx emission and the regulated engine emissions. Generally the fleets in western Europe is composed of newer vehicles than in Sweden. The utilisation of the vehicles may also vary in different countries.
About Data	The calculations of data on heavy trucks are based on the fuel consumption of the vehicle. The fuel consumption data have been obtained by simulations of heavy vehicles in traffic under Swedish conditions. These simulations were made by Volvo Trucks and Scania, especially for NTM. The data on emissions are based on measurements in accordance with applicable standards for certification.
Notes	The person stated as ''Practitioner'' is the contact person for the data for truck transportation in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. About Inventory	
Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Michael Björkman, BTL (Bilspedition Transportation and Logistics), contact person for road transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Björkman, Michael - BTL (Bilspedition Transportation and Logistics), 412 97 Göteborg .
Reviewer	
Applicability	The ambition with the data was to get a picture of future energy use and emissions. The data represents best available technology, not yet in use.
About Data	The data is based on tests on the engine performed in a laboratory according to a new test cycle (proposed for standardisation). This means that several parameters that influence the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially.
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Heavy truck with trailer, max 60 tonnes, manufactured after 1996 [Euro 2]

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Heavy truck with trailer, max 60 tonnes, manufactured after 1996 [Euro 2]
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is representative for Swedish domestic traffic if *empty trips are not included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of a diesel driven heavy truck with trailer, with engine manufactured after 1996 (Euro 2 environmental standard). The towcar for the equipage is a truck, max 24 tonnes. The equipage is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The equipage is also permitted in Finland. Maximum gross weight: 60 tonnes. Kerb weight: 20 tonnes. Available loading capacity with regard to weight: 40 tonnes. Length 24 metres.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents trucks with engine manufactured after 1996
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission factors obtained by the ECE R49 test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level (see specific QMetaData for a description on methods used for each flow). The *quantity value for the energy use* refer to average fuel consumption, *the maximum and minimum value* refer to changes in the efficiency of the engine due to degeneration. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, the quantity value* refer to an average engine guaranteed by Volvo Truck Corporation, the *maximum value* refer to an engine run 500 000 km. No minimum value was given.
Literature Reference	
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

Practitioner	Björkman, Michael - BTL (Bilspedition Transportation and Logistics), 412 97 Göteborg .
Reviewer	
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal

The collection and distribution routes are generally performed by smaller vehicles

--*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport.
--*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited
--*Parcel goods (<100 kg)* are normally handled in small vehicles

The following vehicles and equipages are used for transportation in Sweden:
--*Truck max 3,5 tonnes* is mainly used for transportation of parcels.
--*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic.
--*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic.
--*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods.
--*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland.
--*Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic.

Utilisation level
The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low.

The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden):
-excavated materials and round timber - 50%
-manufactured products (wholesale goods) - slightly more than 20%
-provisions and animal forage - approx. 15%
-mixed cargo (general goods) approx - 10 %.

The Swedish fleet
The data for different age categories of vehicles (before 92, 1992-1995, after 96) may be used to calculate average energy use and emissions for a specific fleet or the average Swedish fleet of vehicles regarding age distribution. In Sweden, 1996 the following shares of transportation work was carried out by the different age categories:
After 1996: 10 %
95-92: 33%
Before 1992 52 %
The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes.

Bulky goods
The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.

Fuel
The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions.

Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions.

International road transports
The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.

About Data

Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc.

Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years.

The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle

	that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions. A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute. The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

Method: See QMetaData for NOx.	Output	Emission	CO	0.09		0.74	g	Air	
Date concieved: 1997-01-01 Data type: Derived, unspecified Method: The emission per tonkm was calculated from the fuel consumption using the carbon content in the diesel. ***The following data was used in the calculations:*** *Assumptions given by the Swedish Road Haulage Association:* -Average fuel consumption 0,45 l/km. -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1 given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm -CO2 emission: 73 g/MJ fuel See QMetaData for the Diesel flow for further information	Output	Emission	CO2	41	41	42	g	Air	
Method: See QMetaData for NOx.	Output	Emission	HC	0.09		0.15	g	Air	
Date concieved: 1997-01-01 Data type: Derived, unspecified Method: The emissions per tonkm were calculated using emission factors obtained by a standardised test cycle, ECE R49 on the engine. The emission factors are given in g/kWh, where kWh refers to mechanical work done by the engine. The quantity value refer to an average engine guaranteed by Volvo Truck Corporation, the maximum value refer to voluntary European emission regulations for diesel engines before 1992. No minimum value was given. *The following formula was used to calculate the emissions per tonkm:* (Average fuel consumption [l/km]*thermal value[kWh (fuel)/l]*efficiency [kWh(engine)/kWh(fuel)]*emission factor [g/kWh(engine)])/ (loading capacity [tonne]*utilisation level) ***The following data was used in the calculations:*** *Assumptions given by the Swedish Road Haulage Association:* -Average fuel consumption 0,45 l/km -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1 given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm *The emission factors were: Quantity value, i.e. average engine:*: -NOx 11 g/kWh -HC 1,5 g/kWh -CO 1,5 g/kWh -Particles 0,4 g/kWh (estimated) -Degree of efficiency on the engine:39 % (assumed) The data was supplied by the Volvo Truck Corporation. *Maximum value, i.e.*	Output	Emission	NOx	0.67	0.55	0.87	g	Air	

voluntary European emission regulations: -NOx 14 g/kWh -HC 2,5 g/kWh -CO 12 g/kWh -Particles - g/kWh (not given) -Degree of efficiency on the engine: 39 %. No minimum value was given. *The ECE R49 is a steady state cycle for heavy duty truck engines*. Consists of a sequence of 13 constant engine speed and load modes. Emissions are analysed for each test mode. Then the overall emission result is calculated as a (weighted) average from all test modes. The cycle is characterised by high average engine load and high exhaust gas temperature. Notes: Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially.									
Method: See QMetaData for NOx.	Output	Emission	Particles	0.024			g	Air	
Date concieved: 1997-01-01 Data type: Derived, unspecified Method: The emission per tonkm was calculated from the fuel consumption using the sulphur content in the diesel ***The following data was used in the calculations:*** *Assumptions given by the Swedish Road Haulage Association:* -Average fuel consumption 0,45 l/km. -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1 given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm See QMetaData for the Diesel flow for further information	Output	Emission	SO_2	0.00026	0.00026	0.00027	g	Air	

About Inventory	
Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Michael Björkman, BTL (Bilspedition Transportation and Logistics), contact person for road transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use

	today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.

Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles --*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. --*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited --*Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used for transportation in Sweden:*** --*Truck max 3,5 tonnes* is mainly used for transportation of parcels. --*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. --*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. --*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. --*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. --*Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***The Swedish fleet*** The data for different age categories of vehicles (before 92, 1992-1995, after 96) may be used to calculate average energy use and emissions for a specific fleet or the average Swedish fleet of vehicles regarding age distribution. In Sweden, 1996 the following shares of transportation work was carried out by the different age categories: After 1996: 10 % 95-92: 33% Before 1992 52 % The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions.

	Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.
About Data	Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years. The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions. A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute. The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Heavy truck with trailer, max 60 tonnes, manufactured between 1992 and 1995 [Euro1]

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Heavy truck with trailer, max 60 tonnes, manufactured between 1992 and 1995 [Euro1]
Functional Unit	1 tonkm, 70 %

Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is representative for Swedish domestic traffic if *empty trips are not included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of a diesel driven heavy truck with trailer with engine manufactured between 1992 and 1995 (Euro 1 environmental standard). The towcar for the equipage is a truck, max 24 tonnes. The equipage is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The equipage is also permitted in Finland. Maximum gross weight: 60 tonnes. Kerb weight: 20 tonnes. Available loading capacity with regard to weight: 40 tonnes. Length 24 metres.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: $SO2$ -tax regulated $CO2$. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents trucks with engine manufactured between 1992 and 1995
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data	
General Activity QMetaData	
Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission factors obtained by the ECE R49 test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level (see specific QMetaData for a description on methods used for each flow). The *quantity value for the energy use* refer to average fuel consumption, *the maximum and minimum value* refer to changes in the efficiency of the engine due to degeneration. The emissions of $CO2$ and $SO2$ is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, the quantity value* refer to an average engine guaranteed by Volvo Truck Corporation and the *maximum value* refer to the emission regulations for diesel engines according to the emission standard Euro I.
Literature Reference	
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year’s time. In such a case, different types of vehicles and utilisation levels may have occurred.

Flow Table and Specific Meta Data

Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles --*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. --*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited --*Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used for transportation in Sweden:*** --*Truck max 3,5 tonnes* is mainly used for transportation of parcels. --*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. --*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. --*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. --*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. --*Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips.* During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15%

	-mixed cargo (general goods) approx - 10 %. ***The Swedish fleet*** The data for different age categories of vehicles (before 92, 1992-1995, after 96) may be used to calculate average energy use and emissions for a specific fleet or the average Swedish fleet of vehicles regarding age distribution. In Sweden, 1996 the following shares of transportation work was carried out by the different age categories: After 1996: 10 % 95-92: 33% Before 1992 52 % The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.
About Data	Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years. The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions. A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute. The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Heavy truck with two trailers, long distance, Euro 0

Administrative	
Finished	Y
Date Completed	1998 - 08
Copyright	NTM
Availability	Public

Technical System	
Name	Heavy truck with two trailers, long distance, Euro 0
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is considered to be representative for Swedish domestic long-distance traffic if *empty trips are not included.*
Process Type	Gate to gate
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of heavy truck with two trailers for long distance transports, approximately 24 m long with a curb weight of 60 tons and a maximum load of 40 tons. Fuel: diesel, MK 1 (sulphurous content: 2 ppm). Fuel consumption: high 5,5 l/10 km, medium 4,9 l/10 km, low 4,3 l/10 km. Engine type: Euro 0 (1987-1992). Utilisation level: 70% by weight.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	Data are valid for trucks produced 1987 - 1992
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data	
General Activity QMetaData	
Date Conceived	1998 - 08

Data Type	Derived, unspecified
Represents	NTM
Method	Data have been put together for NTM by a group of manufacturers and hauliers, i.e. Volvo, Scania, BTL, ASG, Swedish Hauliers Assosiation. Data are presented in relation to the transport work, in g/tonkm. The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic and 70 % for long distance transport with heavy trucks. The utilisation level is based on the load carrying weight, i.e. the weight on which the customer price is based. This means that bulky cargo is multiplied with a factor in order to compensate for taking up volume. The average break-point density is 275 kg/m3. Energy use and emissions per tonkm with a truck should be based on the load carrying weight. The *quantity value for the energy use* refer to average fuel consumption, the *maximum and minimum value* refer to changes in the fuel consumption due to degeneration, driving behavour etc.. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, The emission data have been produced through simulations conducted by Volvo Trucks and Scania in 1997. The simulations were based on certification values for engines and fuel consumption under actual operation for Swedish conditions. For medium and light lorries, the emission values have been obtained from certification values for new engines that are operated in accordance with established operating cycles, e.g. ECR-49 (IVL and Mercedes). Emissions data related to fuel consumption Emission factors (g/liter) Euro 0 Euro 1 Euro 2 Law from: 1980 1990 1993 1996 NOx 52+/- 5 44 27 23 HC 6+/- 2 2.1 1.8 1.3 PM 3+/- 2 1 0.5 0.35 CO 8+/- 3 3.7 3.4 2.5 This shows emissions factors in g/l for heavy lorries. With fuel consumption as a basis, it is possible to calculate the emissions. The data on emissions are based on measurements in accordance with applicable standards for certification. liters/100 km Empty Full load Distribution lorry (Payload 8.5 ton) 20-25 25-30 Med.-size lorry (Payload 14 ton) 25-30 30-40 Heavy lorry w trailer (Payl. 26 ton) 22-27 32-38 Heavy lorry w 2 trail. (Payl. 40 ton) 28-33 43-55*
Literature Reference	
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

About Inventory

Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation

Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	- Swedish haulages and transport companies .
Reviewer	None, to be reviewed. -
Applicability	The data should not be used for any detailed study of transport systems. More detailed information is needed in order to carry out such studies, e.g. regarding the vehicle -type -age and performance, fuel type, the nature of the goods, the utilisation level etc. For a specific transport, the company carrying out the transport should be contacted in order to get information on how the goods are handled and how the transport is carried out. Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred. The standard values presented in this activity should not be used if specific information on the fuel consumption for the transport is availiable. In this case, the fuel consumption should instead be used as a basis to calculate the emissions from the transport. See General QMetaData for emission factors that can be used to calculate emissions per litre fuel used. The age categories of the vehicles compiled in the work are: Older than 1990, Euro 0: Introduced 1987, law from 1990 Euro 1: Introduced 1991, law from 1993 Euro 2: Introduced 1993, law from 1996 However, in order to improve the accuracy of the calculations, the user ought to know the Euro-class (emission standards) of the vehicle, rather than to base the calculations on the age of the vehicle. ***Handling of goods*** The data presented by NTM is representative for a terminal based transport system. The vehicles can be used in different ways, primarily altering the degree of utilisation. Several other types of road based cargo transport systems is not well described by the data (e.g. oil and excavated materials) Terminal based road transports generally consists of 1-3 parts: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles while the inter-terminal traffic is operated by larger units, typically with a higher degree of utilisation. *--Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. *--General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited *--Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used in terminal based transport systems in Sweden:*** *--Parcel truck/van, max 3,5 tonnes* is mainly used for transportation of parcels. *--Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. *--Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. *--Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. *--Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. *--Truck with semi-trailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for an utilisation level of 70 % which is considered representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally

	have an utilisation level of 50 % (i.e. full load one way and empty return trip, due to specialised vehicles). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than smaller firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1, except for petrol driven delivery vans who are assumed to use standard unleaded petrol. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (> 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the data. NGM propose that data from Blinge et. al (Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997) should be used. This study is based on best available technology and Swedish conditions which is likely to yield a low figure. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. This will alter both the SOx emission and the regulated engine emissions. Generally the fleets in western Europe is composed of newer vehicles than in Sweden. The utilisation of the vehicles may also vary in different countries.
About Data	The calculations of data on heavy trucks are based on the fuel consumption of the vehicle. The fuel consumption data have been obtained by simulations of heavy vehicles in traffic under Swedish conditions. These simulations were made by Volvo Trucks and Scania, especially for NTM. The data on emissions are based on measurements in accordance with applicable standards for certification.
Notes	The person stated as ''Practitioner'' is the contact person for the data for truck transportation in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

Technical system description	Operation of heavy truck with two trailers for long distance transports, approximately 24 m long with a curb weight of 60 tons and a maximum load of 40 tons. Fuel: diesel, MK 1 (sulphurous content: 2 ppm). Fuel consumption: high 5,5 l/10 km, medium 4,9 l/10 km, low 4,3 l/10 km. Engine type: Euro 2 (1996-). Utilisation level: 70% by weight.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	Data are valid for trucks produced 1993 - 1999
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests

Flow Data

General Activity QMetaData

Date Conceived	1998 - 08
Data Type	Derived, unspecified
Represents	NTM
Method	Data have been put together for NTM by a group of manufacturers and hauliers, i.e. Volvo, Scania, BTL, ASG, Swedish Hauliers Assosiation. Data are presented in relation to the transport work, in g/tonkm. The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic and 70 % for long distance transport with heavy trucks. The utilisation level is based on the load carrying weight, i.e. the weight on which the customer price is based. This means that bulky cargo is multiplied with a factor in order to compensate for taking up volume. The average break-point density is 275 kg/m3. Energy use and emissions per tonkm with a truck should be based on the load carrying weight. The *quantity value for the energy use* refer to average fuel consumption, the *maximum and minimum value* refer to changes in the fuel consumption due to degeneration, driving behavour etc.. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, The emission data have been produced through simulations conducted by Volvo Trucks and Scania in 1997. The simulations were based on certification values for engines and fuel consumption under actual operation for Swedish conditions. For medium and light lorries, the emission values have been obtained from certification values for new engines that are operated in accordance with established operating cycles, e.g. ECR-49 (IVL and Mercedes). Emissions data related to fuel consumption Emission factors (g/liter) Euro 0 Euro 1 Euro 2 Law from: 1980 1990 1993 1996 NOx 52+/- 5 44 27 23 HC 6+/- 2 2.1 1.8 1.3 PM 3+/- 2 1 0.5 0.35 CO 8+/- 3 3.7 3.4 2.5 This shows emissions factors in g/l for heavy lorries. With fuel consumption as a basis, it is possible to calculate the emissions. The data on emissions are based on measurements in accordance with applicable standards for certification. liters/100 km Empty Full load Distribution lorry (Payload 8.5 ton) 20-25 25-30 Med.-size lorry (Payload 14 ton) 25-30 30-40 Heavy lorry w trailer (Payl. 26 ton) 22-27 32-38 Heavy lorry w 2 trail. (Payl. 40 ton) 28-33 43-55*
Literature Reference	

Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

About Inventory

Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	- Swedish haulages and transport companies .
Reviewer	None, to be reviewed. -
Applicability	The data should not be used for any detailed study of transport systems. More detailed information is needed in order to carry out such studies, e.g. regarding the vehicle -type -age and performance, fuel type, the nature of the goods, the utilisation level etc. For a specific transport, the company carrying out the transport should be contacted in order to get information on how the goods are handled and how the transport is carried out. Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred. The standard values presented in this activity should not be used if specific information on

the fuel consumption for the transport is availiable. In this case, the fuel consumption should instead be used as a basis to calculate the emissions from the transport. See General QMetaData for emission factors that can be used to calculate emissions per litre fuel used.

The age categories of the vehicles compiled in the work are:
Older than 1990,
Euro 0: Introduced 1987, law from 1990
Euro 1: Introduced 1991, law from 1993
Euro 2: Introduced 1993, law from 1996
However, in order to improve the accuracy of the calculations, the user ought to know the Euro-class (emission standards) of the vehicle, rather than to base the calculations on the age of the vehicle.

Handling of goods
The data presented by NTM is representative for a terminal based transport system. The vehicles can be used in different ways, primarily altering the degree of utilisation. Several other types of road based cargo transport systems is not well described by the data (e.g. oil and excavated materials)
Terminal based road transports generally consists of 1-3 parts:
1. Collection of the goods to terminal
2. Long-distance transport between terminals
3. Distribution of the goods from terminal
The collection and distribution routes are generally performed by smaller vehicles while the inter-terminal traffic is operated by larger units, typically with a higher degree of utilisation.

--Wholesale goods (>1000 kg) are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport.
--General goods (100-1000 kg) are generally handled via terminal. The goods may be both weight and volume limited
--Parcel goods (<100 kg) are normally handled in small vehicles

The following vehicles and equipages are used in terminal based transport systems in Sweden:
--Parcel truck/van, max 3,5 tonnes is mainly used for transportation of parcels.
--Light truck, max 8 tonnes is used for local distribution, mainly in city traffic.
--Truck, max 18 tonnes is used for district distribution and local distribution in city traffic.
--Truck, max 24 tonnes is mainly used for transportation of general (styckegods) and wholesale (partigods) goods.
--Heavy truck with trailer, max 60 tonnes is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland.
--Truck with semi-trailer, max 42 tonnes is used for international long-distance traffic.

Utilisation level
The data is only applicable for an utilisation level of 70 % for long distance transport and 50 % for local distribution and regional transport, which is considered representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip, due to specialised vehicles). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than smaller firms of haulage. The utilisation of company internal vehicles is generally low.

The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden):
-excavated materials and round timber - 50%
-manufactured products (wholesale goods) - slightly more than 20%
-provisions and animal forage - approx. 15%
-mixed cargo (general goods) approx - 10 %.

Bulky goods
The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.

Fuel
The fuel used is diesel environmental class 1, except for petrol driven delivery vans who are assumed to use standard unleaded petrol. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (> 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions.

Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the data. NGM propose that data from Blinge et. al (Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997) should be used. This study is based

	on best available technology and Swedish conditions which is likely to yield a low figure. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. This will alter both the SOx emission and the regulated engine emissions. Generally the fleets in western Europe is composed of newer vehicles than in Sweden. The utilisation of the vehicles may also vary in different countries.
About Data	The calculations of data on heavy trucks are based on the fuel consumption of the vehicle. The fuel consumption data have been obtained by simulations of heavy vehicles in traffic under Swedish conditions. These simulations were made by Volvo Trucks and Scania, especially for NTM. The data on emissions are based on measurements in accordance with applicable standards for certification.
Notes	The person stated as ''Practitioner'' is the contact person for the data for truck transportation in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: Heavy truck with two trailers, long distance, made before 1990

Administrative	
Finished	Y
Date Completed	1998 - 08
Copyright	NTM
Availability	Public

Technical System	
Name	Heavy truck with two trailers, long distance, made before 1990
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is considered to be representative for Swedish domestic long-distance traffic if *empty trips are not included.*
Process Type	Gate to gate
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of heavy truck with two trailers for long distance transports, approximately 24 m long with a curb weight of 60 tons and a maximum load of 40 tons. Fuel: diesel, MK 1 (sulphurous content: 2 ppm). Fuel consumption: high 5,5 l/10 km, medium 4,9 l/10 km, low 4,3 l/10 km. Engine type: made before 1990. Utilisation level: 70% by weight.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2.

	Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	Data are valid for trucks produced before 1990
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Michael Björkman, BTL (Bilspedition Transportation and Logistics), contact person for road transports in the work of NGM --
Intended User	Suppliers and buyers of goods

General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Björkman, Michael - BTL (Bilspedition Transportation and Logistics), 412 97 Göteborg .

Applicability	The ambition with the data was to get a picture of future energy use and emissions. The data represents best available technology, not yet in use.
About Data	The data is based on tests on the engine performed in a laboratory according to a new test cycle (proposed for standardisation). This means that several parameters that influence the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially.
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Heavy truck, max 18 tonnes, manufactured after 1996 [Euro 2]

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Heavy truck, max 18 tonnes, manufactured after 1996 [Euro 2]
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is representative for Swedish domestic traffic if *empty trips are not included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of a diesel driven truck with engine manufactured after 1996 (Euro 2 environmental standard). The vehicle is mainly used for district distribution and local distribution in city traffic. Maximum gross weight: 18 tonnes. Kerb weight: 9,5 tonnes. Available loading capacity with regard to weight: 8 tonnes. Length 9 metres.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents trucks with engine manufactured after 1996
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data	
General Activity QMetaData	
Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission factors obtained by the ECE R49 test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level (see specific QMetaData for a description on methods used for each flow). The *quantity value for the energy use* refer to average fuel consumption, *the maximum and minimum value* refer to changes in the efficiency of the engine due to degeneration. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, the quantity value* refer to an average engine guaranteed by Volvo Truck Corporation, the *maximum value* refer to an engine run 500 000 km. No minimum value was given.
Literature Reference	

Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

Reviewer	
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles --*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. --*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited --*Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used for transportation in Sweden:*** --*Truck max 3,5 tonnes* is mainly used for transportation of parcels. --*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. --*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. --*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. --*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport*. The vehicle is also permitted in Finland. --*Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden):

	-excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***The Swedish fleet*** The data for different age categories of vehicles (before 92, 1992-1995, after 96) may be used to calculate average energy use and emissions for a specific fleet or the average Swedish fleet of vehicles regarding age distribution. In Sweden, 1996 the following shares of transportation work was carried out by the different age categories: After 1996: 10 % 95-92: 33% Before 1992 52 % The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.
About Data	Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years. The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions. A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute. The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

Flow Data

General Activity QMetaData	
Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission factors obtained by the ECE R49 test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level (see specific QMetaData for a description on methods used for each flow). The *quantity value for the energy use* refer to average fuel consumption, the *maximum and minimum value* refer to changes in the efficiency of the engine due to degeneration. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, the quantity value* refer to an average engine guaranteed by Volvo Truck Corporation and the *maximum value* refer to voluntary European emission regulations for diesel engines before 1992.
Literature Reference	
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

weight. *Data for the fuel, diesel environmental class 1 given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm See QMetaData for the Diesel flow for further information									

About Inventory	
Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Michael Björkman, BTL (Bilspedition Transportation and Logistics), contact person for road transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Björkman, Michael - BTL (Bilspedition Transportation and Logistics), 412 97 Göteborg .
Reviewer	
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles --*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. --*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited --*Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used for transportation in Sweden:*** --*Truck max 3,5 tonnes* is mainly used for transportation of parcels. --*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. --*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. --*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and

wholesale (partigods) goods.
--*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport*. The vehicle is also permitted in Finland.
--*Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic.

Utilisation level
The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low.

The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden):
-excavated materials and round timber - 50%
-manufactured products (wholesale goods) - slightly more than 20%
-provisions and animal forage - approx. 15%
-mixed cargo (general goods) approx - 10 %.

The Swedish fleet
The data for different age categories of vehicles (before 92, 1992-1995, after 96) may be used to calculate average energy use and emissions for a specific fleet or the average Swedish fleet of vehicles regarding age distribution. In Sweden, 1996 the following shares of transportation work was carried out by the different age categories:
After 1996: 10 %
95-92: 33%
Before 1992 52 %
The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes.

Bulky goods
The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.

Fuel
The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions.

Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions.

International road transports
The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.

About Data

Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc.

Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years.

The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions.

A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute.

The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).

Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Heavy truck, max 18 tonnes, manufactured between 1992 and 1995 [Euro1]

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Heavy truck, max 18 tonnes, manufactured between 1992 and 1995 [Euro1]
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is representative for Swedish domestic traffic if *empty trips are not included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of a diesel driven truck with engine manufactured between 1992 and 1995 (Euro 1 environmental standard). The vehicle is mainly used for district distribution and local distribution in city traffic. Maximum gross weight: 18 tonnes. Kerb weight: 9,5 tonnes. Available loading capacity with regard to weight: 8 tonnes. Length 9 metres.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents trucks with engine manufactured between 1992 and 1995

Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission factors obtained by the ECE R49 test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level (see specific QMetaData for a description on methods used for each flow). The *quantity value for the energy use* refer to average fuel consumption, *the maximum and minimum value* refer to changes in the efficiency of the engine due to degeneration. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, the quantity value* refer to an average engine guaranteed by Volvo Truck Corporation and the *maximum value* refer to the emission regulations for diesel engines according to the emission standard Euro I.
Literature Reference	
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

In Sweden, 1996 the following shares of transportation work was carried out by the different age categories: After 1996: 10 % 95-92: 33% Before 1992 52 % The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.

About Data	Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years. The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions. A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute. The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Heavy truck, max 24 tonnes, future

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Heavy truck, max 24 tonnes, future
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is representative for Swedish domestic traffic if *empty trips are not included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden

Technical system description	Operation of a diesel driven heavy truck with engine representing best available technology (proposed Euro 3 environmental standard) with oxidation filter and catalytic control. The vehicle is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. Maximum gross weight: 24 tonnes. Kerb weight: 10 tonnes. Available loading capacity with regard to weight: 14 tonnes. Length 24 metres.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO_2 -tax regulated CO_2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents best available technology, not yet in regular use.
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission factors obtained by a new test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level. See specific QMetaData for each flow.
Literature Reference	
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year’s time. In such a case, different types of vehicles and utilisation levels may have occurred.

Flow Table and Specific Meta Data

QMetaData	***Direction***	***FlowType***	***Substance***	***Quantity***	***Min***	***Max***	***Unit***	***Environment***	***Geography***
	Input	Cargo	Cargo	1			tonne	Technosphere	
Date concieved: 1997-01-01 Data type: Unspecified, expert outspoke Method: The diesel consumption per tonkm was calculated using assumptions on average fuel consumption (l/km) and utilisation level. The fuel is assumed to be diesel, environmental class 1. The minimum and maximum value is based on assumptions on changes in the efficiency of the engine due to degeneration. ***The following data was used in the calculations:***	Input	Refined resource	Diesel environmental class 1	1.27			MJ	Technosphere	

Assumptions given by the Swedish Road Haulage Association: -Average fuel consumption: 0,37 l/km. -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1, given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm *Change of efficiency of the engine (based on assumptions):* -minimum value: 0,99 in relation to the average engine -maximum value:1,01 in relation to the average engine									
	Output	Cargo	Cargo	1			tonne	Technosphere	
Method: See QMetaData for NOx	Output	Emission	CO	0.014			g	Air	
Date concieved: 1997-01-01 Data type: Derived, unspecified Method: The emission per tonkm was calculated from the fuel consumption using the carbon content in the diesel. ***The following data was used in the calculations:*** *Assumptions given by the Swedish Road Haulage Association:* -Average fuel consumption 0,37 l/km. -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1 given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm -CO2 emission: 73 g/MJ fuel See QMetaData for the Diesel flow for further information	Output	Emission	CO2	93			g	Air	
Method: See QMetaData for NOx	Output	Emission	HC	0.014			g	Air	
Date concieved: 1996-01-01 Data type: Derived, unspecified Method: The emissions per tonkm were calculated using emission factors (g/kWh) obtained by a a new test cycle, on the engine. The emission factors are given in g/kWh, where kWh refers to mechanical work done by the engine. The tests was perfomed by Motortestcenter. *The following formula was used to calculate the emissions per tonkm:* (Average fuel consumption [l/km]*thermal value[kWh (fuel)/l]*efficiency [kWh(engine)/kWh(fuel)]*emission factor [g/kWh(engine)])/(loading capacity [tonne]*utilisation level) **The following data was used in the calculations:** *Assumptions given by the Swedish Road Haulage Association:* -Average fuel consumption 0,37 l/km -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1:* Thermal value: 43,43 MJ/kg Density: 0,81 kg/l Sulphur content: 10 ppm The data were supplied by the Swedish Petroleum Institute *The emission factors were:* -NOx 6,3 g/kWh -HC 0,4 g/kWh -CO 0,7 g/kWh -Particles 0,11 g/kWh -Degree of efficiency on the engine: 41 % (assumption). The data can be found in Ahlvik. Date concieved: 1997-01-01 Data type: Derived, unspecified Method: The emission per tonkm was calculated from the fuel consumption using the sulphur content in the diesel ***The following data was used in the***	Output	Emission	SO2	0.00056			g	Air	

***calculations:** Assumptions given by the Swedish Road Haulage Association:* -Average fuel consumption 0,37 l/km. -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1 given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm See QMetaData for the Diesel flow for further information									

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Michael Björkman, BTL (Bilspedition Transportation and Logistics), contact person for road transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.

Applicability	The ambition with the data was to get a picture of future energy use and emissions. The data represents best available technology, not yet in use.
About Data	The data is based on tests on the engine performed in a laboratory according to a new test cycle (proposed for standardisation). This means that several parameters that influence the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially.
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission factors obtained by the ECE R49 test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level (see specific QMetaData for a description on methods used for each flow). The *quantity value for the energy use* refer to average fuel consumption, *the maximum and minimum value* refer to changes in the efficiency of the engine due to degeneration. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, the quantity value* refer to an average engine guaranteed by Volvo Truck Corporation, the *maximum value* refer to an engine run 500 000 km. No minimum value was given.
Literature Reference	
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

Reviewer	
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles *--Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. *--General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited *--Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used for transportation in Sweden:*** *--Truck max 3,5 tonnes* is mainly used for transportation of parcels. *--Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. *--Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. *--Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. *--Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. *--Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***The Swedish fleet*** The data for different age categories of vehicles (before 92, 1992-1995, after 96) may be used to calculate average energy use and emissions for a specific fleet or the average Swedish fleet of vehicles regarding age distribution. In Sweden, 1996 the following shares of transportation work was carried out by the different age categories: After 1996: 10 % 95-92: 33% Before 1992 52 % The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel

	environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.
About Data	Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years. The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions. A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute. The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

Name	Heavy truck, max 24 tonnes, manufactured before 1992 [Euro 0]
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is representative for Swedish domestic traffic if *empty trips are not included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport

Owner	Sweden
Technical system description	Operation of a diesel driven heavy truck with engine manufactured before 1992 (Euro 0 environmental standard). The vehicle is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. Maximum gross weight: 24 tonnes. Kerb weight: 10 tonnes. Available loading capacity with regard to weight: 14 tonnes. Length 24 metres.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents trucks with engine manufactured before 1992
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission factors obtained by the ECE R49 test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level (see specific QMetaData for a description on methods used for each flow). The *quantity value for the energy use* refer to average fuel consumption, the *maximum and minimum value* refer to changes in the efficiency of the engine due to degeneration. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, the quantity value* refer to an average engine guaranteed by Volvo Truck Corporation and the *maximum value* refer to voluntary European emission regulations for diesel engines before 1992.
Literature Reference	
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Michael Björkman, BTL (Bilspedition Transportation and Logistics), contact person for road transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of

	organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.

Practitioner	Björkman, Michael - BTL (Bilspedition Transportation and Logistics), 412 97 Göteborg .
Reviewer	
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles --*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. --*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited --*Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used for transportation in Sweden:*** --*Truck max 3,5 tonnes* is mainly used for transportation of parcels. --*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. --*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. --*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. --*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. --*Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***The Swedish fleet*** The data for different age categories of vehicles (before 92, 1992-1995, after 96) may be used to calculate average energy use and emissions for a specific fleet or the average Swedish fleet of vehicles regarding age distribution. In Sweden, 1996 the following shares of transportation work was carried out by the different age categories: After 1996: 10 % 95-92: 33% Before 1992 52 % The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes.

	Bulky goods The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.
About Data	Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years. The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions. A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute. The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Heavy truck, max 24 tonnes, manufactured between 1992 and 1995 [Euro1]

Administrative

Technical System	
Name	Heavy truck, max 24 tonnes, manufactured between 1992 and 1995 [Euro1]
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is representative for Swedish domestic traffic if *empty trips are not included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of a diesel driven heavy truck with engine manufactured between 1992 and 1995 (Euro 1 environmental standard). The vehicle is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. Maximum gross weight: 24 tonnes. Kerb weight: 10 tonnes. Available loading capacity with regard to weight: 14 tonnes. Length 24 metres.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents trucks with engine manufactured between 1992 and 1995
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data	
General Activity QMetaData	
Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission factors obtained by the ECE R49 test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level (see specific QMetaData for a description on methods used for each flow). The *quantity value for the energy use* refer to average fuel consumption, *the maximum and minimum value* refer to changes in the efficiency of the engine due to degeneration. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, the quantity value* refer to an average engine

	guaranteed by Volvo Truck Corporation and the *maximum value* refer to the emission regulations for diesel engines according to the emission standard Euro I.
Literature Reference	
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles --*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. --*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited --*Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used for transportation in Sweden:*** --*Truck max 3,5 tonnes* is mainly used for transportation of parcels. --*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. --*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. --*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. --*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. --*Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no

	general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***The Swedish fleet*** The data for different age categories of vehicles (before 92, 1992-1995, after 96) may be used to calculate average energy use and emissions for a specific fleet or the average Swedish fleet of vehicles regarding age distribution. In Sweden, 1996 the following shares of transportation work was carried out by the different age categories: After 1996: 10 % 95-92: 33% Before 1992 52 % The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.
About Data	Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years. The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions. A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute. The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different

	transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: High purity copper production from primary raw materials

Administrative	
Finished	Y
Date Completed	1995
Copyright	Metall/ Berlin Metall Verla 1947-
Availability	Full availability

Technical System	
Name	High purity copper production from primary raw materials
Functional Unit	1 kg pure copper
Functional Unit Explanation	
Process Type	Gate to gate
Site	None
Sector	Materials and components
Owner	None
Technical system description	2.13 tons of copper concentrate containing 12% water are transported to mainly one plant in Germany where it is melted and refined to copper. The concentrate is melted in a suspension process with H_2SO_4 recycling in a converter with low slag production. 0.57 tons of scrap copper is added. The raw metal is refined and cast to anodes. The final refining is made through electrolysis to pure copper metal. H_2SO_4, copper slag, copper anode sludge and $NiSO_4$ are byproducts.

System Boundaries

Notes	The total energy use for primary production is 21.8 MJ/kg (6.3 MJ for copper production and 15.5 for energy production). A German electricity mix is used and described (in wastes and emissions) as well as the energy from fossil sources. Values in terms of MJ/km for different transports are given with the specific emissions connected to them. The energy use for a number of help materials is included. The production of H2SO4 requires 13% of the primary energy used for the primary production.

Commissioner	- None .
Practitioner	- None .
Reviewer	- None
Applicability	Can be used for western industrial countries. Best available technology in western Germany.
About Data	
Notes	If a cradle to gate process is to be calculated, data for ore mining and concentration (data set ''Copper ore mining and concentration'') has to be added. For the primary production of pure copper products 0.57 of the values for ore mining and concentration should be added which for energy is 20MJ/kg. This because the emissions and energy use are expressed per kg copper in concentrate and the copper content is assumed to be 30 weight%.

SPINE LCI dataset: High purity copper production from secondary raw materials

Administrative

Finished	Y

Date Completed	1995
Copyright	Metall/ Berlin Metall Verla 1947-
Availability	Full availability

Technical System

Name	High purity copper production from secondary raw materials
Functional Unit	1 kg of pure copper
Functional Unit Explanation	
Process Type	Gate to gate
Site	Germany
Sector	Materials and components
Owner	Germany
Technical system description	0.58 tons of different secondary raw materials (slags, ashes, sludges) and 1.4 tons of copper scrap (copper, brass, bronze) are transported, melted and refined. The scrap is added in different steps, some to the first melting and refining of the low grade raw materials and some directly to the refining through electrolysis. Copper slag, fly ash, copper anode sludge and NiSO4 are produced as byproducts.

About Data	
Notes	

SPINE LCI dataset: High sea shipping

Administrative	
Finished	Y
Date Completed	1994-04-01
Copyright	
Availability	Public

Technical System	
Name	High sea shipping
Functional Unit	tonkm
Functional Unit Explanation	The energy use and exhaust emissions are calculated with reference to the transportation of 1 ton goods, 1 kilometre.
Process Type	Unit operation
Site	Sweden
Sector	Sea transport
Owner	Sweden

Technical system description	Operation of a ship used for high sea shipping

System Boundaries	
Nature Boundary	Emissions to air from combustion of the fuel are included. Other environmental impacts from the operation of the ship are not included.
Time Boundary	The aim was that the figures would represent the fleet in 1992.
Geographical Boundary	Sweden and other countries with a similar fleet
Other Boundaries	Utilisation level of the ship is not known. *Not included in the system:* Production and distribution of the fuel Manufacture and maintenance of the ship
Allocations	
Systems Expansions	

Flow Data	
General Activity QMetaData	
Date Conceived	1990-1994
Data Type	Derived, unspecified
Represents	German average
Method	Data compiled from*different literature sources*. The emissions were calculated from emission factors; the emission factor for each specific substance was multiplied with the energy use for the given transport. The emission factors were: SO2 1,28 g/MJ NOx 2,5 g/MJ CO 0,22 g/MJ CO2 72 g/MJ HC 0,06 g/MJ Particles 0,11 g/MJ For details on how the emission factors were obtained, see metadata for each specific substance. Metadata for CO and HC can be found under CO. Metadata for SO2 and particles can be found under SO2.

Notes:	Input	Cargo	Cargo	1.000000			tonne	Technosphere	
Date concieved: 1990 Data type: Unspecified Method: The data for energy use for high sea shipping recommended by Tillman were found in Lenner. The recommendation was based on the energy use for high sea shipping found in Habersatter (0,2 MJ/tonkm). The energy use reported by Lenner are intended to represent an average value for all shipping in Sweden. The value is therefore a combination of several types of ships with energy use between 0,09 MJ/tonkm and 0,349 MJ/tonkm. Lenner found the energy use for different types of ships, loads and average speeds in figure A3:2 in Cordi. Cordi has however not stated how the background material for figure A3:2 was retrieved. Literature: Habersatter, K. ''Oekobilanz von Packstoffen - Stand 1990''. Schriftenreihe Umwelt nr 132, Bundesamt fur Umwelt, Walt und Landschaft (BUWAL), Bern 1991.Lenner, M. ''Energiförbrukning och avgasemission för olika transporttyper'' VTI-meddelande nr 718, Statens Väg- och Trafikinstitut, 1993 Cordi, I et al, ''Energieffektiviteten för person- och godstransporter i Sverige. depending on e. g. size, shape of the hull, hydrodynamic properties and engine strength. This can give a very broad distribution in the energy use depending on which individu									
Notes:	Output	Cargo	Cargo	1.000000			tonne	Technosphere	
Date concieved: 1992 Data type: Unspecified Method: Lenner has calculated *average emission factors* in g/tonkm, intended to represent an average value for all shipping in Sweden. They are therefore calculated for a combination of several types of ships. Emission factors in g/MJ were obtained by division of the emission factors in g/tonkm by the average energy use (0,051 g/MJ). Lenner has not stated how the values were retrieved. Literature: Lenner, M. `Energiförbrukning och avgasemission för olika transporttyper` VTI-meddelande nr 718, Statens Väg- och Trafikinstitut, 1993 Notes:	Output	Emission	CO	0.04			g	Air	
Date concieved: 1992 Data type: Modeled data Method: The emission factor was calculated from the fuel use (0,18 g/MJ) using the carbon content in diesel. The data used in the calculation was: Heat value: 42,82 MJ/kg Density: 0,83 kg/dm3 CO2 emission: 2,61 kg CO2/dm3 fuel Literature: Lenner, M. `Energiförbrukning och avgasemission för olika transporttyper` VTI-meddelande nr 718, Statens Väg- och Trafikinstitut, 1993 Notes:	Output	Emission	CO2	13			g	Air	
Notes:	Output	Emission	HC	0.011			g	Air	
Date concieved: 1992 Data type: Unspecified Method: Lenner has calculated an *average emission factor* in g/tonkm, intended to represent an average value for all shipping in Sweden. They are therefore calculated for a combination of several types of ships. Emission factors in g/MJ were obtained by division of the emission factors in g/tonkm by the average energy use (0,051 g/MJ). The data was based on figures found in a document written by the Swedish Environmental Agency (Planeringsunderlag..). The emission factors in this document are given for four-stroke engines, and based on an investigation of exhaust emissions from shipping in Sweden made by Alexandersson. Data on specific emissions given in Alexandersson were mainly based on data from laboratory measurements by engine manufacturers but also measurements onboard three ships and other projects that has conducted measurements onboard sailing ships. Literature: Alexandersson, A. ''Sjöfartens utsläpp av avgaser'' TFB-meddelande nr 164, Transportforskningsdelegationen, Stockholm 1990. Lenner, M. ''Energiförbrukning och avgasemission för olika transporttyper'' VTI-meddelande nr 718, Statens Väg- och Trafikinstitut, 1993 Planeringsunderlag för samordnad investeringsplanering 1994-2003. Statens Naturvårdsverk 1992-04-15 Notes:	Output	Emission	NOx	0.45			g	Air	
Notes:	Output	Emission	Particles	0.02			g	Air	
Date concieved: 1991 Data type: Unspecified Method: Exhaust emission factors in g/tonkm can be read in figure 25 in Alexandersson. To obtain emission factors in g/MJ, Tillman has divided the emission factors in g/tonkm with an energy use of 0,47 MJ/tonkm Figure 25 in Alexandersson is based on total exhaust	Output	Emission	SO2	0.23			g	Air	

emissions and transportation by domestic shipping in Sweden 1987. It is not however clear how the background data for figure 25 were collected. Literature: Alexandersson, A. ''Sjöfartens utsläpp av avgaser'' TFB-meddelande nr 164, Transportforskningsdelegationen, Stockholm 1990. Notes:									

About Inventory	
Publication	Tillman, A-M. `Goods transportation in life cycle assessment. Standard values for energy consumption and emissions.` In: Life Cycle Assessment - Inventory Analysis Methodology: Overview, Recycling, Electricity and Transports, Swedish Waste Research Council (AFR) report nr 74, April 1995 -- Documentation and review of the report done by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	LCA practitioners
General Purpose	To fulfil a need for *standard values* to calculate energy use and exhaust emissions from goods transports.
Detailed Purpose	An update of standard values for energy use and exhaust emissions from an earlier investigation in: *Tillman, A-M., Baumann, H., Eriksson, E., Rydberg, T.* `Livscykelanalyser för förpackningsmaterial - beräkning av miljöbelastning` SOU 1991:77, Allmänna förlaget, Stockholm, 1991.
Commissioner	- .
Practitioner	Tillman, Anne-Marie - Technical Environmental Planning Chalmers University of Technology 412 96 Göteborg Sweden .
Reviewer	Pålsson, Ann-Christin - CPM Technical Environmental Planning Chalmers University of Technology 412 96 Göteborg
Applicability	*Reviewers comment:* The data should be used with great care. The energy use for different types of ships can vary depending on e. g. size, shape of the hull, hydrodynamic properties and engine strength. This can give a very broad distribution in the energy use depending on which individual ships the energy use were based.
About Data	The emissions were calculated from the energy use and emission factors. The emission factors that were used and the basis for them can be found in general metadata.
Notes	

SPINE LCI dataset: Hot rolling of steel sheet

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Hot rolling of steel sheet
Functional Unit	1 kg hot rolled steel sheet
Functional Unit Explanation	Before the steel can be coated, different pre treatments has to be done. The steel from the steel mill is first hot rolled and then pickled. After the pickling process, the steel is cold reduced and then finally coated.
Process Type	Gate to gate

Site	SSAB Tunnplåt
Sector	Materials and components
Owner	SSAB Tunnplåt
Technical system description	This activity describes a process step included in the system ''Production of plywood boxes'', also available in the SPINE@CPM database. Plywood boxes are used to pack the coated and non-coated roller bearings from SKF, Göteborg, during the transportation to customers. The plywood boxes are manufactured by Nefab Emballage AB in Alfta, Sweden. The plywood box consist of plywood, steel strips, steel nails and wooden splits. The steel for the steel strips and steel nails is hot rolled, pickled, cold reduced and finally coated at SSAB Tunnplåt`s line in Borlänge. This dataset describes the hot rolling of 1 kg steel sheet at SSAB Tunnplåt AB in Borlänge. All data for the hot rolling processes is obtained from an already made LCA at Nefab Emballage AB: Hillvall Maria; Transportförpackningars bidrag till reduktion av miljöbelastningen; Master Thesis at the Technical University of Luleå; 2000. The data refers to an existing EPD from SSAB Tunnplåt AB: Environmental Product Declaration from SSAB; SE 380; June 1999

System Boundaries

Nature Boundary	Emissions to air and water are included. The steel scrap from the process is reused as raw material and is thus not considered as waste, but as a co-product ending in the technosphere.
Time Boundary	This environmental profile refers to the mean values of emissions to which hot rolling of steel sheet gives rise in Borlänge during the years 1998-1999.
Geographical Boundary	The hot rolling of steel sheet takes place at SSAB Tunnplåt´s line in Borlänge, Sweden.
Other Boundaries	The production of electricity is NOT included in the dataset, but must be followed from the cradle in order to obtain the total environmental impact. This must also be done with the production of LPG and the production of oil.
Allocations	Allocations have been made according to weight.
Systems Expansions	Not applicable

About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. Both types of bearings are packed in a plywood box. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The dataset is applicable to hot rolling of steel sheet at SSAB Tunnplåt AB in Borlänge.
About Data	All data for the process is obtained from an earlier LCA study at Nefab Emballage AB: Hillvall Maria; Transportförpackningars bidrag till reduktion av miljöbelastningen; Master Thesis at the Technical University of Luleå; 2000. The data refers to an existing EPD from SSAB Tunnplåt AB: Environmental Product Declaration from SSAB; SE 380; June 1999.
Notes	

SPINE LCI dataset: Hungary, electricity generation mix 1998

Administrative

Finished	Y
Date Completed	2001-01-31
Copyright	IEA
Availability	Public

Technical System

Name	Hungary, electricity generation mix 1998
Functional Unit	Total electricity produced during 1998
Functional Unit Explanation	The electricity mix refer to the total amount of electricity generated by different power sources expressed in GWh during the year 1998.
Process Type	Unit operation
Site	Hungary
Sector	Energyware
Owner	Hungary
Technical system description	The generation of electricity with different power generating systems in Hungary during the year 1998.

System Boundaries

Nature Boundary	Not applicable, since the data only refer to the electricity generation mix. The environmental load for generation of electricity is not included.
Time Boundary	The data refer to 1998.
Geographical Boundary	Only electricity produced in Australia is considered. Import or export of electricity is not included.
Other Boundaries	-
Allocations	Not applicable
Systems Expansions	Not applicable

About Inventory

Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.

Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998

Technical System

Name	HVO combustion in heavy duty truck or bus, Euro VI, tank-to-wheel, f3 fuels
Functional Unit	1 MJ
Functional Unit Explanation	1 MJ input of HVO to vehicle tank
Process Type	Gate to grave
Site	
Sector	Fuel
Owner	
Technical system description	The data represent emissions from hydrotreated vegetable oil (HVO) combustion in heavy duty truck or bus, Euro VI, tank-to-wheel. The emission legislation uses the definition of a heavy duty vehicle having a gross weight of 3.5 tons or more. The reported emission factors should be considered as generic data, and it should be noted that the emissions for a specific vehicle and a specific mission might differ from those generic data. For example, the limit values for certification of engines have been used as basis for deriving some of the emission factors. The duty cycles used for certification are defined to cover the whole range of typical loads of an engine in different operations. The operation of a specific vehicle can however differ from the duty cycle used in the certification, resulting in different emissions than calculated with the generic emission factors. E.g. for the regulated emissions: nitrous oxides, particles, total organic compounds and carbon monoxide, the values are conservative based on the maximum emissions limits per kWh of engine output when driving at the best point (the optimal engine speed/torque operating point). In reality, the values are often lower.

General Activity QMetaData

Date Conceived	
Data Type	
Represents	German average
Method	The emission factors (EF, kg/MJ) for the regulated emissions have been estimated based on WHTC (World Harmonized Transient Cycle for truck and bus engines), legislation limits for Euro VI (Commission Regulation (EC) No 582/2011).The WHTC cycle is for heavy duty engines and vehicle (www.dieselnet.com). Equation for calculation of emission factors for fuel use: Efficiency: 0.44 (?)= (energy work/energy in fuel) which is the efficiency at the best point (the optimal engine speed/torque operating point) and which gives the maximum emission factors within the legislation limit. EF fuel use (g/MJ)=EF work (g/kWh)/3.6*? Emissions of CO2 and SO2 have been calculated based on carbon- and sulphur content in the fuel, see documentation "Data compilation method for a specific flow" and "Reference" in the Flow table. Emissions of CH4 was calculated from JRC (2013) and N2O was best estimate.

SPINE LCI dataset: Hydro electricity energy system, EPD-version

Administrative	
Finished	Y
Date Completed	1996-10
Copyright	Bundesamt für energie, Bern
Availability	Public

Technical System	
Name	Hydro electricity energy system, EPD-version
Functional Unit	1 TJ net electricity from power plant
Functional Unit Explanation	The generation of 1 TJ (1 000 000 000 000 J) net electricity (i.e. electricity need in the power plant has been supplied for by the plant itself). Electricity distribution and distribution losses are not accounted for, i.e. not for this particular unit process. Data about distribution and its losses may however be found in the original study.
Process Type	Cradle to grave
Site	UCTPE countries Europe
Sector	Grid electricity and district heat
Owner	UCTPE countries Europe
Technical system description	Reported figures are based on data from a LCI-study performed at ETH, Zürich and Paul Scherrer Institut, Villigen, ''Ökoinventare von Energiesystemen'', 3rd edition 1996 and adapted to the demands of the EPD-guidelines (Environmental Product Declaration guidelines in Sweden). The main emphasis in ETH:s study has been in the description of hydro power plants typical for Switzerland and the alpine region, with power outputs between about 0.1 MW and 350 MW. Three types of power plants are distinguished, namely, run of river (without storage), water storage and pumped storage power plants. All subsystems are described on a ''cradle-to-grave'' basis, including the main stages, i.e.

	data concerning consumption of resources, waste handling and emissions is included for the manufacturing of main materials and energyware used in the lifecycle. Energyware (fuels and electricity) is used during construction (ground works), in material manufacturing processes, transports etc. Figures reported here are based on LCI results for two types of plants: hydro power plants with and without storage and represent the average hydro power in the UCPTE* countries 1990-1994. Average hydro power production in the UCPTE was 158 TWh/year in 1990-94 (plants with storage:48%, plants without storage 52%). The average operation time was about 2900 hours per year. Detailed data concerning the construction and demolition of hydro power plants including storages, has been gathered by ETH, i.e. figures reported here comprise only construction and demolition of hydro power plants. The following has been inventoried: - manufacture of materials from natural resources and scrap - manufacture of capital goods (rough estimation) - exploration and extraction of energyware - transports - ground works (excavation etc) - waste handling (different kinds of landfills, waste incineration plants) Energyware consumed in pumps used for seasonal storage has been accounted for. Following parameters and activities have been taken into account by ETH: consumption of cement, steel and explosives, transports, consumption of energyware during the construction phase (electricity and diesel), use of land, usable content in water storages, amount of turbine water. Figures concerning the three latter parameters are not reported here but are described under ''other boundaries''. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.

System Boundaries

Nature Boundary	Used materials and energyware have been followed from extraction and processing of natural resources. Maufacturing processes for the use of recycled material are accounted for. Emissions from energyware use in manufacturing processes and transports (infrastructure and vehicle construction included) are considered as well as emissions from landfills (infrastructure included) where waste material is disposed of. Waste material supposed to be recycled are outputs of the system (i.e. those recycling processes are not included). ETH:s LCI-results comprise all parameters received during inventory and calculation, i.e. no selection has been made by ETH. Vattenfall's criterion in selecting and aggregating ETH's LCI-results for electricity generation in the UCPTE region has been to make the figures usable as general electricity LCI data in EPDs according to Miljöstyrningsrådets guidelines. Especially parameters (emissions) which have established impact indices - accepted by the EPD system - for one or several environmental impact categories, have been picked out and aggregated as far possible. But also metal and energyware resources have been included, as well as waste, in spite of all waste handling processes related to this dataset being included with respect to use of resources and emissions. The latter is an adaption to other LCI data for electricity generation where waste amounts are reported (since those flows have not been followed to the grave). Since ETH claimes that most of the figures regarding metal emissions have an undefined amount of datagaps all metal emissions are aggregated except for a few which are specified separatly since they are reported for most processes in the lifecycle. Metals are reported as elements although they often are part of compounds. Measuring methods often just give the amounts of the different elements found. All hydrocarbons to water are aggregated to one parameter as well as halogenated organics, since no indices exist (that are accepted by the EPD system so far) for characterisation of the individual substances.
Time Boundary	The figures describe the average operation of studied plants in 1994. Figures concerning fuel extraction and processing represent an average of the early nineties. Descriptions and figures of different technical processes come from literature, contractors, public and private institutions and describe the situation of the late eighties. Electricity used during the lifecycle has been assumed to be a mix based on the average generation in the UCPTE* countries between 1990-94 (to level off the large variations in hydro power production over the years). All processes, also those conducted in the past, have been assumed to use average technology of the early nineties.

	Different technical lifetimes/reference times for different parts and materials of the studied systems have been used as follows: Alpine hydro power plants Low pressure hydro power with and without storage plants (rivers and channels) Cement 200 years 80 years Steel, reinforcement 100 years 80 years Steel, other 60 years 60 years Explosives 250 years 100 years Transports 150 years 60 years Energyware, construction 150 years 80 years * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Geographical Boundary	No geographical boundaries have been drawn except concerning the location of the studied plants in Switzerland and the consumption of generated electricity in the UCPTE* region. Processes conducted outside the UCPTE* region are supposed to be supplied with UCPTE* electricity. Data concerning the use of resources, emissions and waste in connection with manufacturing processes mainly originate from sources in Switzerland, Germany and other western European countries. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Other Boundaries	Manufacturing processes of components and machines have been approximated with 50% of the energyware used to produce contained materials. Energyware figures concerning material production come from literature and have assumed to be a mix of 10% UCPTE electricity, 45% oil and 45% natural gas. This approximation has been confirmed in more thorough calculations in ETH:s LCA for coal power. The ETH study comprises figures concerning use of land, usable content in water storages and amount of turbine water which have not been reported here. The two latter have been excluded due to lack of corresponding data in comparable studies. Use of land has been excluded here because of ETH's advanced approach. Land is divided into two main groups - land and sea - which are subdivided into 4 categories each. Land Criterion Category Natural human impact not larger than other species' since the indutrial revolution I Modified human impact larger than other species', low degree of culivation II Cultivated human impact larger than other species', large degree of cultivation III Built upon dominated by buildings, roads, dams, mines etc. IV Category I is not used in the study. State of land before, during and after exploitation is of intererst. If a piece of land is used again after some kind of exploitation it will either end up in the same category or in a higher one. ETH takes into account not only the land used during the technical lifetime of the studied system but also during the construction phase and during the time it takes to restore the land. they express use of land in the unit m2year which is different from comparable Swedish studies (m2). See times for restoration of land below: From category IV to category III 5 years From category III to category II 50 years From category II to category I 100 000 years (For uranium mines the restoration time to category II is 80'000 years due to elevated radiation caused by long-living radioactive compounds.) ETH specifies about 160 radioactive isotopes emitted to air and water. Radioactive emissions reported here are picked out in accordance with SETAC working group report on data quality and data availability (to be published in 2001). Big accidents occuring seldomly are not included.The threshold is fixed at 10 accidents per year if one energy carrier/system (e.g. oil) would cover the entire primary energy demand of the world.
Allocations	The water flow in rivers is regulated not just to assure a electricity generation adapted to the electricity need but also to protect land from overflooding. All environmental load in connection with water regulation (dams etc) has however been layed on hydro power. The cutoff-method has been used for material use, i.e. 100% of the environmental load for virgin and recycled material used in the lifecycle is included whereas no environmental load has been considered for materials leaving the system to be recycled. Landfill processes and waste incineration, however, are included for waste arising during the lifecycle.

Publication	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz. ETH, Eidgenössische Technische Hochschule, Zürich, Gruppe Energie - Stoffe - Umwelt (ESU), Paul Scherrer Institut, Villigen/Würenlingen, Sektion Ganzheitliche Systemanalysen Available on CD-ROM with full documentation (in German) at http://www. energieforschung.ch -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by (see also Notes): Rolf Frischknecht, ESU-services, Switzerland Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	Original study of ETH: LCA pra
General Purpose	The purpose of the ETH study was to examine a number of energy systems quantitatively and to the same extent with respect to environmental issues during their lifecycles. The results can be used in lifecycle assessments, as basis information in decisionmaking regarding environmental optimisation or in working with municipal energy plans. Vattenfalls purpose - as a commissioner of putting ETH:s data into Spine format with metadata - is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines. Data is supposed to be used together with IEA statistics about electricity generation mixes in the OECD countries/regions.
Detailed Purpose	ETH:s aim was to examine some important aspects of the environmental impact of hydro power plants in the UCPTE. The consumption of cement, steel, explosives and energyware during the construction phase is considered as well as transports, usable content of storages and the amount of water passing the turbines. Plants with and without storages are studied.
Commissioner	BEW, PSEL - Bundesamt für Energiewirtschaft, Projekt- und Studienfonds der Elektrizitätswirtschaft .
Practitioner	Rolf Frischknecht et al - ETH, Eidgenössische Technische Hochschule, Institut für Energietechnik, Zürich and Paul Scherrer Institut, Sektion Ganzheitliche Systemanalyse, Villingen/Würenlingen .
Reviewer	None, see further under notes -
Applicability	The LCI-results of the three types of plants studie in the ETH study are valid for hydro power in Switzerland but are supposed to be a rather good approximation for hydro power in UCPTE. The two types, hydro power plants with and without storage, have been summarized to one set of data ''Hydro Power in UCPTE'' in accordance with existing percentages of those types of plants in the UCPTE region. Only this aggregated set of data is reported here. The result of the third type of hydro power plant is reported under the name ''Hydro Power with pumped storage in UCPTE'' in ETH's study (this kind of power plant is used to convert base load to peak load electricity with an efficiency of about 70%). This set of data is aggregated and documented in accordance with the Swedish EPD-guidelines to be used in combination with IEA statistics concerning electricity generation mixes in OECD countries and regions together with other datasets - based on the ETH study - describing other power generation systems. The EPD-adapted power generation systems in Spine format are named as follows: Fuel gas electricity energy system, EPD-version Biofuel electricity energy system (approximation), EPD-version Hydro electricity energy system, EPD-version Lignite electricity energy system, EPD-version Nuclear electricity energy system, EPD-version Stone coal electricity energy system, EPD-version Wind electricity energy system, EPD-version

	IEA statistics for generation mixes 1998 exist in Spine format for the following 30 countries/regions: OECD total OECD North America OECD Pacific OECD Europe European Union Australia Austria Belgium Canada Czech Rpublic Denmark Finland France Germany Greece Hungary Iceland Ireland Italy Japan Korea Luxembourg Mexico Netherlands New Zealand Norway Poland Portugal Spain Sweden Switzerland Turkey United Kingdom United States
About Data	Only the most important construction materials have been inventoried as well as transports and energyware consumption during the construction phase, i.e. consumption of copper, concrete additives or possible recycling processes of scrapped material etc. have been excluded. Data quality regarding inventoried material and energyware amounts is high, since the sources are reliable. The division of the steel consumption in the three different steel qualities has however been estimated. Due to difficulties in finding detailed data regarding the construction of studied plants (some data has been estimated) the results should be seen as approximate. Material manufacturing processes have been inventoried with a low degree of exactitude (except for steel, cement, aluminium, copper, bitumen, and platinum group metals for which rather detailed LCI data are provided). Results are reported with three figures, but it is stated in the original source that this does not mean that accuracy is that high (Part III, p.16). For references and sources of reported figures see further under Function, Nature boundary, Publication, Notes and General metadata.
Notes	Reviewer of this specification of ETH:s data and metadata has been: Dr. Rolf Frischknecht, ESU-services (earlier at ETH) - approval of aggregation of figures and of Vattenfall's interpretation ot the documentation Ann-Christin Pålsson, CPM - review of documentation quality according to the CPM data documentation requirements. The technical committee of the Swedish Environmental Management Council - approval of method and aggregation of parameters Project Management of the ETH study, 3rd edition: Professor, Dr. P. Suter and R. Frischknecht, ETH Editorial staff of the 1st edition: R. Frischknecht, P. Hofstetter, I. Knoepfel, M. Ménard, ETH R. Dones, E. Zollinger, Paul Scherrer Institut Authors of the 1st edition: N. Attinger, T. Baumann, G. Doka, R. Dones, R. Frischknecht, H.-P. Gränicher, C. Grasser, P. Hofstetter, I. Knoepfel, M. Ménard, H. Müller, M. Vollmer, E. Walder, E. Zollinger Authors of the revision, 3rd edition: U. Bollens, S, Bosshart, M. Ciot, L. Ciseri, G. Doka, R. Frischknecht, R Hischier, A. Martin, ETH R. Dones, U. Gantner, Paul Scherrer Institut -- --- Changes made to the data set after publishing in SPINE@CPM--- >>> 6 June 2001: <<< Changes made by Ann-Christin Pålsson, CPM based on discussions with Caroline Setterwall,

	Vattenfall AB. Comments: The following changes has been made in the nomenclature for in- and outflows: Mangane in ore -> changed to: Manganese in ore CH4 -> changed to: Methane (to be in accordance with the nomenclature specified in CPM report 2000:2) CN -> changed to: CN- Stone coal -> changed to: Hard coal (to be in accordance with the nomenclature specified in CPM report 2000:2) Other metals -> changed to: Metals Explanations of nomenclature (inserted in Notes for the specific flows): - CN- is Cyanide ion - Reactive waste deposit is waste at landfill that is still reactive. - Inert waste deposit is waste at landfill that are inert. Additional clarifications: - Note that the flows of waste in the table of in- and outflows are internal flows, i.e. they do NOT cross the system boundaries. All waste handling processes is included in the study with respect to use of resources and emissions. - Radioactive waste is accounted for in cubic metres. The product specific requirements for electricity and district heating generation (PSR 1998:1) in the Swedish EPD system states that waste shall be accounted for in gram. However, no conversion factors were given in the study. There are also no general conversion factors that are commonly used.

Technical System	
Name	Hydro electricity energy system, ETH - full version
Functional Unit	1 TJ net electricity from power plant
Functional Unit Explanation	The generation of 1 TJ (1 000 000 000 000 J) net electricity (i.e. electricity need in the power plant has been supplied for by the plant itself). Electricity distribution and distribution losses are not accounted for, i.e. not for this particular unit process. Data about distribution and its losses may however be found in the original study.
Process Type	Cradle to grave
Site	UCTPE countries Europe
Sector	Grid electricity and district heat
Owner	UCTPE countries Europe
Technical system description	Reported figures come from a LCI-study performed at ETH, Zürich and Paul Scherrer Institut, Villigen, ''Ökoinventare von Energiesystemen'', 3rd edition 1996. The main emphasis in ETH:s study has been in the description of hydro power plants typical for Switzerland and the alpine region, with power outputs between about 0.1 MW and 350 MW. Three types of power plants are distinguished, namely, run of river (without storage), water storage and pumped storage power plants. All subsystems are described on a ''cradle-to-grave'' basis, including the main stages, i.e. data concerning consumption of resources, waste handling and emissions is included for the manufacturing of main materials and energyware used in the lifecycle. Energyware (fuels and electricity) is used during construction (ground works), in material manufacturing processes, transports etc. Figures reported here are based on LCI results for two types of plants: hydro power plants with and without storage and represent the average hydro power in the UCPTE* countries 1990-1994. Average hydro power production in the UCPTE was 158 TWh/year in 1990-94

	(plants with storage:48%, plants without storage 52%). The average operation time was about 2900 hours per year. Detailed data concerning the construction and demolition of hydro power plants including storages, has been gathered by ETH, i.e. figures reported here comprise only construction and demolition of hydro power plants. The following has been inventoried: - manufacture of materials from natural resources and scrap - manufacture of capital goods (rough estimation) - exploration and extraction of energyware - transports - ground works (excavation etc) - waste handling (different kinds of landfills, waste incineration plants) Energyware consumed in pumps used for seasonal storage has been accounted for. Following parameters and activities have been taken into account by ETH: consumption of cement, steel and explosives, transports, consumption of energyware during the construction phase (electricity and diesel), use of land, usable content in water storages, amount of turbine water. Figures concerning the three latter parameters are not reported here but are described under ''other boundaries''. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.

System Boundaries

Nature Boundary	Used materials and energyware have been followed from extraction and processing of natural resources. Maufacturing processes for the use of recycled material are accounted for. Emissions from energyware use in manufacturing processes and transports (infrastructure and vehicle construction included) are considered as well as emissions from landfills (infrastructure included) where waste material is disposed of. Waste material supposed to be recycled are outputs of the system (i.e. those recycling processes are not included). Land is divided into two main groups - land and sea - which are subdivided into 4 categories each. Land Criterion Category Natural human impact not larger than other species' since the industrial revolution I Modified human impact larger than other species', low degree of cultivation II Cultivated human impact larger than other species', large degree of cultivation III Built upon dominated by buildings, roads, dams, mines etc. IV Category I is not used in the study. State of land before, during and after exploitation is of interest. If a piece of land is used again after some kind of exploitation it will either end up in the same category or in a higher one. ETH takes into account not only the land used during the technical lifetime of the studied system but also during the construction phase and during the time it takes to restore the land. They express use of land in the unit m2year which is different from comparable Swedish studies (m2). See times for restoration of land below: From category IV to category III 5 years From category III to category II 50 years From category II to category I 100 000 years (For uranium mines the restoration time to category II is 80'000 years due to elevated radiation caused by long-living radioactive compounds.) ETH's LCI-results comprise all parameters received during inventory and calculation, i.e. no selection has been made by ETH.
Time Boundary	The figures describe the average operation of studied plants in 1994. Figures concerning fuel extraction and processing represent an average of the early nineties. Descriptions and figures of different technical processes come from literature, contractors, public and private institutions and describe the situation of the late eighties. Electricity used during the lifecycle has been assumed to be a mix based on the average generation in the UCPTE* countries between 1990-94 (to level off the large variations in hydro power production over the years). All processes, also those conducted in the past, have been assumed to use average technology of the early nineties. Different technical lifetimes/reference times for different parts and materials of the studied systems have been used as follows:

	Alpine hydro power plants Low pressure hydro power with and without storage plants (rivers and channels) Cement 200 years 80 years Steel, reinforcement 100 years 80 years Steel, other 60 years 60 years Explosives 250 years 100 years Transports 150 years 60 years Energyware, construction 150 years 80 years * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Geographical Boundary	No geographical boundaries have been drawn except concerning the location of the studied plants in Switzerland and the consumption of generated electricity in the UCPTE* region. Processes conducted outside the UCPTE* region are supposed to be supplied with UCPTE* electricity. Data concerning the use of resources, emissions and waste in connection with manufacturing processes mainly originate from sources in Switzerland, Germany and other western European countries. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Other Boundaries	Manufacturing processes of components and machines have been approximated with 50% of the energyware used to produce contained materials. Energyware figures concerning material production come from literature and have assumed to be a mix of 10% UCPTE electricity, 45% oil and 45% natural gas. This approximation has been confirmed in more thorough calculations in ETH:s LCA for coal power. Big accidents occuring seldomly are not included.The threshold is fixed at 10 accidents per year if one energy carrier/system (e.g. oil) would cover the entire primary energy demand of the world.
Allocations	The water flow in rivers is regulated not just to assure a electricity generation adapted to the electricity need but also to protect land from overflooding. All environmental load in connection with water regulation (dams etc) has however been layed on hydro power. The cutoff-method has been used for material use, i.e. 100% of the environmental load for virgin and recycled material used in the lifecycle is included whereas no environmental load has been considered for materials leaving the system to be recycled. Landfill processes and waste incineration, however, are included for waste arising during the lifecycle.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1985 to 1995
Data Type	Derived, unspecified
Represents	Average hydro power in the UCTPE countries (except pumped storage used for daily regulation of power production)
Method	The figures have been copied from the module ''Electricity from hydro power, UCPTE'' (Strom ab Wasserkraft, UCPTE) in the Ökoinventare von Energiesystemen, ETH Zürich 1996.
Literature Reference	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz, Environmental Life-Cycle Inventories of Energy Systems An Environmental Database for the Accounting of Energy Consumption in Product Life-Cycle Assessment and the Comparative Assessment of Energy systems Prof. Dr. P. Suter, R. Frischknecht, et al Swiss Federal Institute of Technology, Zürich R. Dones, U. Gantner Paul Scherrer Institute, Villigen/Würenlingen
Notes	Multiple flows are reported for several emissions to air. This is because that in the original study emissions to air have been reported in three categories, indicated by one of the letters below following the substance name. - m = mobile (emissions from vehicles) - p = process (process specific emissions as for instance methane emissions during coal mining) - s = stationary (emissions from stationary combustion plants) This categorisation has however not been documented in this specification in the SPINE format.

About Inventory

Publication	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz. ETH, Eidgenössische Technische Hochschule, Zürich, Gruppe Energie - Stoffe - Umwelt (ESU), Paul Scherrer Institut, Villigen/Würenlingen, Sektion Ganzheitliche Systemanalysen Available on CD-ROM with full documentation (in German) at http://www. energieforschung.ch -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by (see also Notes): Rolf Frischknecht, ESU-services, Switzerland Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	Original study of ETH: LCA pra
General Purpose	The purpose of the ETH study was to examine a number of energy systems quantitatively and to the same extent with respect to environmental issues during their lifecycles. The results can be used in lifecycle assessments, as basis information in decisionmaking regarding environmental optimisation or in working with municipal energy plans.
Detailed Purpose	ETH:s aim was to examine some important aspects of the environmental impact of hydro power plants in the UCPTE. The consumption of cement, steel, explosives and energyware during the construction phase is considered as well as transports, usable content of storages and the amount of water passing the turbines. Plants with and without storages are studied.
Commissioner	BEW, PSEL - Bundesamt für Energiewirtschaft, Projekt- und Studienfonds der Elektrizitätswirtschaft .
Practitioner	Rolf Frischknecht et al - ETH, Eidgenössische Technische Hochschule, Institut für Energietechnik, Zürich and Paul Scherrer Institut, Sektion Ganzheitliche Systemanalyse, Villingen/Würenlingen .
Reviewer	None, see further under notes -
Applicability	The LCI-results of the three types of plants studied in the ETH study are valid for hydro power in Switzerland but are supposed to be a rather good approximation for hydro power in UCPTE. The two types, hydro power plants with and without storage, have been summarized to one set of data ''Hydro Power in UCPTE'' in accordance with existing percentages of those types of plants in the UCPTE region. Only this aggregated set of data is reported here. The result of the third type of hydro power plant is reported under the name ''Hydro Power with pumped storage in UCPTE'' in ETH's study (this kind of power plant is used to convert base load to peak load electricity with an efficiency of about 70%).
About Data	Only the most important construction materials have been inventoried as well as transports and energyware consumption during the construction phase, i.e. consumption of copper, concrete additives or possible recycling processes of scrapped material etc. have been excluded. Data quality regarding inventoried material and energyware amounts is high, since the sources are reliable. The division of the steel consumption in the three different steel qualities has however been estimated. Due to difficulties in finding detailed data regarding the construction of studied plants (some data has been estimated) the results should be seen as approximate. Material manufacturing processes have been inventoried with a low degree of exactitude (except for steel, cement, aluminium, copper, bitumen, and platinum group metals for which rather detailed LCI data are provided).

	Results are reported with three figures, but it is stated in the original source that this does not mean that accuracy is that high (Part III, p.16). For references and sources of reported figures see further under Function, Nature boundary, Publication, Notes and General metadata.
Notes	Reviewer of this specification of metadata describing the ETH study has been: Dr. Rolf Frischknecht, ESU-services (earlier at ETH) - approval of Vattenfall's interpretation ot the documentation Ann-Christin Pålsson, CPM - review of documentation quality according to the CPM data documentation requirements Project Management of the ETH study, 3rd edition: Professor, Dr. P. Suter and R. Frischknecht, ETH Editorial staff of the 1st edition: R. Frischknecht, P. Hofstetter, I. Knoepfel, M. Ménard, ETH R. Dones, E. SPINE LCI dataset: Hydro-electric power station with support systems

Administrative	
Finished	Y
Date Completed	1996-12-01
Copyright	
Availability	Public

Technical System	
Name	Hydro-electric power station with support systems
Functional Unit	Net production of 1 kWh electricity
Functional Unit Explanation	The emissions and use of resources and raw materials are associated with the production of 1 kWh electricity.
Process Type	Cradle to gate
Site	Vattenfall - Lule river
Sector	Grid electricity and district heat
Owner	Vattenfall - Lule river
Technical system description	The environmental influence of *operation and maintenance of a hydro-electric power station* are included in the system. Production of materials and chemicals and transports used in association with the operation and maintenance are included. To represent the hydro-electric power plants of Vattenfall, three hydro-electric power plants in river Lule have been studied: • *Seitevare with Tjaktjajaure annual storage basin*, located in a mountain region -an under ground station, with an effect of 214 MW and normal annual production 799 GWh. The basin is filled during the spring, summer and fall and generally tapped between October and April • *Harsprånget* has a large river flow and high drop, and is located in a forest region - under ground plant, with an effect of 940 MW and normal annual

	production 2159 GWh. The plant has five units. • *Boden* has only part of the river flow and medium drop, and is located in a coastal region - an above ground plant, with an effect of t 80 MW and normal annual production 464 GWh. Vattenfall has about 70 wholly-owned and 70 part-owned hydro-electric power stations in Sweden. The electricity production primarily affect river Lule, river Skellefte, river Ume, Ångermanälven, Indalsälven, Dalälven, Motala stream and river Göta. During a normal year, the electricity production in Vattenfall:s plants are 32 TWh, which is about 50 % of the total electricity production by water power in Sweden. All hydro-electric power electricity production are based on two fundamental conditions: water supply and drop. More water and greater drop gives a larger electricity production. The water supply varies during the year, and to use the availalble water supply during the year, reservoirs and power stations are built along the watercourse.

System Boundaries	
Nature Boundary	The analysis starts at one of the water storage basins and then the river are followed through the power plants and dams, tunnels, machine stations and outlets to the outlet into the sea. Flows above the storage basin have been excluded because the environmental effect of the expansion (utbyggnad) above the annual storage facilities are considered to be a small. All emissions are considered equivalent independent of where they take place (locally, regionally, globally; in densely populated areas or rural areas).
Time Boundary	The power plant are assumed to operate during 60 years. The power plants can however operate longer than that. The probability that the power stations will ever be demolished are small.
Geographical Boundary	The analysis are divided into three systems. The three systems represent three representative power stations in river Lule; Seitevare with Tjaktjajaure annual storage basin, Harsprånget and Boden.
Other Boundaries	The studied system include *operation and maintenance of the power plant.* Calculations of building and demolition of the plant has been performed but are not included in this system. ***Sub-systems included in the system:*** • Manufacture and transport of materials for reinvestments and reconstruction • Transports of operation personnel • Known use of chemicals are accounted for. In the cases where it was possible to obtain data, resource use and emissions for manufacture are included. • Use of resources and emissions to air from production of the electricity used in the life cycles. • Energy use and emissions for the production of oil for the studied manufacturing processes and transports. ***Sub-systems excluded from the system:*** • Equipment after the power station transformer are not included. • Emissions at ordinary occurring operation disturbances have only been studied for water power and have been included when the emissions from the operation disturbance are at least 10% of the corresponding emissions from building and normal operation of the water power station.

	• The risk of major accidents and rare breakdowns and environmental consequences from these. • Waste and rest products are transported to final waste. Operation and chemical and biological decomposing processes (nedbrytningsprocesser) in the final waste have not been considered. • Work environment. • Environmental loads caused by the operation personnel.
Allocations	The *50/50 method* has been applied throughout the analysis. The method is described in ''Nordic Guidelines on Life-Cycle Assessment'', Nord 1995:20, The Nordic Council, Stockholm.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	
Data Type	Derived, unspecified
Represents	Average hydro power in the UCTPE countries (except pumped storage used for daily regulation of power production)
Method	An LCA calculation on the operation of a water power plant
Literature Reference	Brännström-Norberg B-M., Dethlefsen U., Johansson R., Setterwall C., Tunbrant S.,''Livscykelanalys för Vattenfalls elproduktion - Sammanfattande rapport'', in Swedish, Vattenfall AB
Notes	Note: The unit for CO is corrected, from g to mg (2000-08-17). The parameters that are presented are chosen because they have a general interest and because the basis for these parameters are relatively good. All values are reported with 3 figures. The data are however seldom that accurate. Emissions of NOx, CO2, CO and SO2 originate primarily from transports in association with operation and maintenance. The choice of power plants in river Lule gives long transport distances. Production of materials also causes relatively large emissions of SO2 and CO2.

About Inventory	
Publication	Brännström-Norberg B-M., Dethlefsen U., Johansson R., Setterwall C., Tunbrant S.,''Livscykelanalys för Vattenfalls elproduktion - Sammanfattande rapport'', Vattenfall AB -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	The data can be used as a basi
General Purpose	• The work with life-cycle analysis are expected to *contribute to a reinforcement and structuring* of the environmental work within Vattenfall, and a deeper knowledge on the use of resources and emissions to the environment. • An LCA can *facilitate a need for reliable data for electricity production.* Electricity is used in the manufacture of almost every product, and data from an LCA can be used when conducting an LCA on products. • An LCA can *facilitate a choice between different techniques* for future electricity production. • An LCA can also help to *choose the most effective alternatives* to reduce the consumption of resources and environmental influence of the current electricity production system. • It is also possible to *compare* the environmental load for different alternatives of electricity production.
Detailed Purpose	To obtain a *reliable basis* to be able to perform life-cycle analyses of different types of electricity use, and to identify opportunities for improvements in the existing system. To identify data gaps and areas where the knowledge are poor.
Commissioner	- Vattenfall Elproduktion .
Practitioner	- Vattenfall Energisystem AB: Britt-Marie Brännström-Norberg Ulrika Dethlefsen Roland Johansson Caroline Setterwall Sofie Tunbrant .
Reviewer	- Thomas Ekvall, Chalmers Industriteknik (CIT) Gunnar Lindfors, Institutet för Vatten- och Luftvårdsforskning (IVL) Göran Finnveden, Institutet för Vatten- och Luftvårdsforskning (IVL)
Applicability	The studied system include operation and maintenance of a hydro-electric power plant. The analysis are based on data from three hydro-electric power plants in river Lule that are chosen to make the analysis *representative for the operation of Vattenfall:s plants.* There are differences between the three power stations. The differences are however not larger than an average value should be representative for the water power along the entire river Lule. The data are reliable since specific plants have been studied. The consequence is however that the result is primarily valid for the studied plants. Thoroughly reliable data for every power source, requires life cycle analyses for a large number of power plants for every power source. Nuclear and water power are the base for Vattenfall:s electricity production system. Vattenfall produces 50 % of the

	electricity produced by water power in Sweden. River Lule has been chosen in the analysis because: • River Lule generates the most electricity, approximately 50% of Vattenfall:s water power production and 1/9 of the entire electricity production of Sweden. • There are annual storage basins in river Lule, which makes it possible to adjust the tapping from a annual storage basin to the variations in water supply from one year to another. • Parts of river Lule are expanded for power, which means that the tapping of water are adjusted to the need of temporary effect increases. The consequence is a more extensive influence on the environment. The environmental influence will then not be underestimated. • Vattenfall is single owner which has made it easier to obtain data. Transmission and distribution losses are not included. When the result is used to study different types of electricity use, these losses should be included. A rough estimate are that the distribution losses for a large industry customer are approximately 5% of the bought electricity, i.e. to obtain data for the use of electricity the data should be multiplied with 1,05. For an average household customer the transmission losses are approximately 10% of the bought electricity, i.e. the data should be multiplied with 1,10. A large share of the *environmental influence associated with water power* are difficult to handle in a life cycle analysis. It is possible to make an inventory of the different types of influence, but difficult to assess quantitatively. The environmental influence are to a large extent direct and local, such as influence on the landscape and biological diversity. The complete study include building, operation and maintenance, and demolition of the power plant. When the data is used for energy production in a life cycle analysis of a product or a system, that do not require expansion of the electricity production system, it however reasonable only to include operation and maintenance. The other phases of the life cycle are the same independent on the electricity production.
About Data	Data for the *power stations are specific* for the respective plant. The reported data are weighted averages of the use of resources and energy for operation of three hydro-electric power plants in river Lule: Seitevare with Tjaktjajaure annual storage basin, Harsprånget and Boden. Relevant data for transports, extraction and production of metals and chemicals, and manufacture and work on important components were hard to obtain. Data from manufacturers and other reports and studies, primarily life cycle analyses have been used. Production of material and transports are considered with current technology. Swedish standard values have been used to calculate fuel use and emissions from transports. Transport distances are specific for the operation of the plant. *The parameters that are presented* are chosen because they have a general interest and because the basis for these parameters are relatively good. All values are reported with 3 figures. The data are however seldom that accurate. Use of materials and chemicals for *operation and reinvestments* of the power plants are generally assumed to give an addition of 1 % per year of the use of resources and emissions at the building phase. Dams, concrete constructions and buildings are however not considered to need to renewal during the lifetime of the power station. The following data has been used in the analysis (tonnes per year during 60 years): Seitevare: Steel 9,43; Copper 0,38; Lead 0,5; Sulphuric acid 0,22 Harsprånget: Steel 71,3; Copper 3,1; Lead 1,17; Sulphuric acid 0,75 Boden: Steel 9,02; Copper 0,24; Lead 0,58; Sulphuric acid 0,26 For electricity used in the manufacture of materials and

		fuels, *average electricity* for the respective countries distributed on different electricity production alternatives have been used. The following *degrees of efficiencies* have been used to calculate the fuel used in the electricity production. The values are standard values for existing power plants. New modern plants have often higher degrees of efficiencies. The values are calculated from the effective heat value in the used fuels and the energy content in the steam produced in a nuclear power plant. • Coal condensing: 40% • Oil condensing: 40% • Natural gas condensing/combination: 40% • Gas turbine: 25% • Combined heat and power plant(irrespective of fuel) 30% (for electricity production) 85% (total for electricity and heat production) • Water power: are not recalculated, but are accounted for as kWh electricity • Nuclear power: 33%, are however not recalculated, but accounted for as kWh electricity or gram natural uranium.
	Notes	There are several known and possible environmental effects at expansion of water power that cannot be quantitatively described: • Influence on the landscape, and a large influence on the area near a regulation reservoir. • A loss of biological diversity, because of large differences in water level before and after the expansion. • Displacement in the population of species influence e.g. the fishing. • The transport of important minerals to the sea are changed. • Roads have been built in mountain regions, which have both positive and negative effects. • Loss of land, and damages to the earth for agriculture. • A more even water flow has reduced the risk of flooding. • Influence on the reindeer breeding because of loss of land, obstruction of movement of reindeer herds etc. To reduce the negative effects, actions like biotope improvements and preservation of some water flow in the river have been used. Today, there are approximately 1000 hydro-electric power plants in Sweden. Most of them are small, 10-100 kW. More than 120 power plants have an effect larger than 20 MW. About 50% of the electricity produced in Sweden is from water power. The remaining share are predominately nuclear power. Of the electricity produced by water power, about 50% are produced in Vattenfall:s plants. The probability that the power stations will ever be demolished are small. A water power plant has low costs and running reinvestments and reconstruction will be done.

SPINE LCI dataset: Hydrogen fuel production by steam reforming of natural gas. ESA-DBP

Administrative	
Finished	Y
Date Completed	2002
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Hydrogen fuel production by steam reforming of natural gas. ESA-DBP
Functional Unit	1 MJ of CGH2 (compressed hydrogen)
Functional Unit Explanation	Compressed hydrogen is the gaseous state of the element hydrogen which is kept under pressure. It can be used for mobile hydrogen storage in hydrogen vehicles. It is assumed that the final pressure of the hydrogen gas stored is 250 bar.
Process Type	Cradle to gate
Site	Unknown
Sector	Energyware
Owner	Unknown
Technical system description	Hydrogen can be used as an energy source for fuel cell vehicles. The fuel cell consists of 3 main elements: cathode, anode and electrolite. It can use hydrogen and oxygen to create electricity by an electro-chemical process. Excerpt from the report (see 'Publication'): ''Hydrogen can be produced from many different sources (fossil hydrocarbons, biomass or water) using different technologies such as electrolysis, steam reforming or gasification.(...) Steam reforming is the most common production process today and the most cost-effective. Normally natural gas is used as the feedstock(...). The energy efficiency is about 75-80% for large scale reforming. If the process is combined with and efficient waste recovery, 85% might be reached.'' During the process ''there will be energy losses in the reformer and compressor. However, since there is no need to compress the natural gas, the energy used for CNG (NB: compressed natural gas) pathway is reduced by 0.05MJ/MJ NG (NB: natural gas). The energy efficiency of the small-scale reformer is 79.8% based on LHV (NB: Lower Heating Value). (...) It is assumed that the final pressure of the hydrogen gas stored is 250 bar and the compression is done by NG-fuelled gas turbines (n=34%); the natural gas used is 0.14MJ/MJ compressed gas.'' There are 3 main steps of producing the hydrogen: 1. NG pathway (exploration, extraction, distribution) 2. Small scale reforming 3. Compression natural gas fuelled This process is included in the system described in: Karlström M. (2002). Environmental Technology Assessment of Introducing Fuel Cell City Buses - A Case Study of Fuel Cell Buses in Göteborg. ESA report 2002:10, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2002--10.pdf Other processes in the CPM Database also included in the above publication: Hydrogen fuel production from on-site electrolysis. ESA-DBP Fuel cell bus run on hydrogen produced in steam reforming process. ESA-DBP Fuel cell bus run on hydrogen produced in electrolysis process. ESA-DBP

System Boundaries	
Nature Boundary	The performed study is cradle-to-gate and it relates to the hydrogen pathway 'well-to tank'. It covers the fuel pathway from feedstock to fuel dispenser nozzle.
Time Boundary	The data were acquired in 2002 as the most up-to-date ones. The data come from 2001.
Geographical Boundary	The study was performed for Sweden.
Other Boundaries	Excerpt from the report, see 'Publication': ''The on-site production of hydrogen has been considered as the near term production option. The reference case of production is from steam reforming because it will probably be the most cost-effective production method. The size of the production facility of

	hydrogen is assumed 3.1 MW, which will be enough for a fleet of 100 buses.''
Allocations	Data were given for 1 MJ of hydrogen.
Systems Expansions	Not applicable.

Intended User	LCA practitioner
General Purpose	Excerpt from the report (see 'Publication'): ''The main goal is an environmental assessment of the use of fuel cell buses on bus route 60 in Göteborg. Environmental assessments involve the gathering, evaluation and synthesize of data and methods using engineering and scientific research to help address an environmental decision making situation. This assessment is made to decide whether to invest in a new technology for fuel cell buses by 2006 or to rely on other bus technologies. (...) The main goal is divided into 3 parts. the first goal of this study is to describe the technical system, methodology used, and frame of the problem. In the future when real investment decision will be made, this study could then help frame an actual investment decision. The second goal is to present environmental performance results for the different alternative bus technologies. The results address emissions, health effects, and financial investments. The third goal is to describe and assess the uncertainties of the results.''
Detailed Purpose	Hydrogen is an energy source for a fuel cell and its production is presented in the reference report. Hydrogen production by steam reforming of a natural gas is the most cost-effective way of production. Determining the inventory data for this process is an important part of the study.
Commissioner	MISTRA - .

Excerpt from the report (see 'Publication'): ''Hydrogen can be produced from many different sources (fossil hydrocarbons, biomass or water) using different technologies such as electrolysis, steam reforming or gasification.(...) Hydrogen from electricity by electrolysis is one of the most well-known and simpliest methods to produce hydrogen.'' The first step of the process is delivering the electricity to the electrolyser. The electrolyser produces hydrogen with 30 bar of pressure. It is transfered to the compression electrical pumps where also some electricity (for producing 1 MJ of compressed hydrogen, 0.065MJ is needed for this stage) is provided. ''The energy efficiency of the electrolyser is 65.1% (LHV) (NB: LHV - Lower Heating Value), which means that 1/0.651=1.53MJ electricity is used per MJ H2. The electric pumps (n=50% for small plants) used to compress the hydrogen are use =0.0652 MJ Electricity/MJ CGH2. The total electricity demand per CGH2=1.536+9.0652=1.60MJ. The distribution loss of electricity is 6%. Then the demand is 1.60*1.06=1.697MJ electricity.'' This process is included in the system described in: Karlström M. (2002). A fuel cell reaction separates the oxidation at the anode and the reduction at the cathode with an electolyte, which allows the ions to move between the two electrodes. (...) Hydrogen from electricity by electrolysis is one of the most well-known and simpliest methods to produce hydrogen. Only electricity and pure water is needed to produce extremely pure hydrogen. However only about 4% of the hydrogen produced today in the world is from electrolysis. (...). The major problem with electrolysis is the high cost of electricity when compared with steam reforming of natural gas in most countries. However there are benefits such as its flexibility, simplicity, reliability and purity of the product. Furthermore, the plant is locally non-polluting in itself and if the electricity is made from renewable source, such as hydropower, solar energy, or wind energy, then the potential for reduction of greenhouse gases is substantial. The electrolysis technology is modular in its design, making it possible to design the process over a wide range of scales from a few kilowatts to hundreds of megawatts. Three different technologies for water electrolysis are available. They differ depending on what kind of electrolyte is used. The most common and the only commercial alternative today is based on alkaline technology using liquid KOH as electrolyte. (...) The electrolyzers normally have efficiency [hydrogen output (HHV)/electricity input) 70-85% (NB: HHV - Higher Heating Value).''

SPINE LCI dataset: Hydrotreated Vegetable Oil - Palm oil, cradle-to-gate, system expansion - f3 fuels

Functional Unit	1 MJ

Functional Unit Explanation	1 MJ Hydrotreated Vegetable Oil - Palm oil
Process Type	Cradle to gate
Site	
Sector	Fuel
Owner	
Technical system description	Production (cradle to gate) of Hydrotreated Vegetable Oil (HVO), produced from Palm oil. The data is based on several data sources (see References) and based on data sets for each process step. An LCA model has been complied within this f3 project (see Additional information). This data set is the result of this LCA model. Neste oil (Finland) produces HVO from palm oil, rape seed oil and from animal fat. The HVO sold on the market under the name NExBTL is a mix of HVO from these three raw materials. The mix varies, but in 2012 it was 64.5% from palm oil, 0.3% from rape seed, jathropa and camelina oil, as well as 35.1% from waste and residues (animal fat, waste fish processing fat, fatty acid from palm and stearin). The heat value for the HVO mix is 44.1 MJ/kg (4) and the average density is 780 kg/m3 (4 & 5). The LCA model was divided in three stages: agricultural stage, processing stage and HVO production. In every life cycle stage transportation is included. The LCA model includes direct affected processes, overhead (operation of buildings, administration, etc.) and capital goods (building, machinery and means of transportation). All electricity is assumed to be European average. Emissions of pesticides are assumed to be received by air (33%), soil (33%) and water (33%). Palm oil mill effluent (POME) is assumed to be treated in open anaerobic-aerobic ponds. Empty fruit bunches are applied as mulch in the plantation. The total amount of shells and fibers from palm fruits are assumed to be burned in boiler to produce steam and electricity. It is assumed that all palm kernel oil extraction takes place using mechanical extraction. The palm is grown, harvested and refined into crude oil in Malaysia. The fuel component is refined into the fuel product in Kilpilahti, Porvoo, Finland. Finally the fuel product is distributed to tank service stations in Finland. Ommited data: - The production of seeds during agricultural stage has been ommited; - Production of cypermethrin, warfarin and fungicides has been omitted; - Methane emissions from oil palm plantation have been ommited; - No capital goods or overhead for the HVO production facility is included in the model. - Chemicals used to treat POME are not accounted for. - Lubricating oil is ommited from the inventory of the processing stage.

System Boundaries

Nature Boundary	
Time Boundary	2010 - 2013

Technical System	
Name	Hydrotreated Vegetable Oil - Rapeseed oil, cradle-to-gate, system expansion - f3 fuels
Functional Unit	1 MJ
Functional Unit Explanation	1 MJ Hydrotreated Vegetable Oil - Rapeseed oil
Process Type	Cradle to gate
Site	
Sector	Fuel
Owner	
Technical system description	Production (cradle to gate) of Hydrotreated Vegetable Oil (HVO), produced from Rapeseed Oil. The data is based on several data sources (see References) and based on data sets for each process step. An LCA model has been complied within this f3 project (see Additional information). This data set is the result of this LCA model. Neste oil (Finland) produces HVO from palm oil, rapeseed oil and from animal fat. The HVO sold on the market under the name NExBTL is a mix of HVO from these three raw materials. The mix varies, but in 2012 it was 64.5% from palm oil, 0.3% from rapeseed, jathropa and camelina oil, as well as 35.1% from waste and residues (animal fat, waste fish processing fat, fatty acid from palm and stearin). The heat value for the HVO mix is 44.1 MJ/kg (4) and the average density is 780 kg/m3 (4 & 5). The LCA model was divided in three stages: agricultural stage, processing stage and HVO production. In every life cycle stage transportation is included. The LCA model includes direct affected processes, overhead (operation of buildings, administration, etc.) and capital goods (building, machinery and means of transportation). Electricity in agricultural and processing stages is assumed to be Danish production mix, while in HVO production stage it is assumed to be European average (UCTE mix). It is assumed that 87% of the straw is left on the field, and 13% is used for energy purposes. Emissions of pesticides are assumed to be received by air (33%), soil (33%) and water (33%). Emissions generated by burning of straw are assumed to be equivalent to burning of softwood in furnace. Rapeseed oil is extracted by utilization of hexane as solvent. Residual rapeseed from screening process of incoming rapeseed is sent to biogas production. The rapeseed is grown, harvested and refined into crude oil in Danmark. Data for processing stage refers to AarhusKarlshamn refinery, in Aarhus, Danmark. The fuel component is refined into the fuel product in Kilpilahti, Porvoo, Finland. Finally the fuel product is distributed to tank service stations in Finland. Ommited data: - Magnesium, sulphur and boron fertilisers are not taken into account; - Dust emissions and soil erosion are omitted; - No indirect NO emissions from the field are accounted for; - Lubricating oil and cleaning agents are omitted from processing stage; - Recycling of paper, plastic, metals, lubricating oil, as well as waste to landfill are omitted from processing stage; - No capital goods or overhead for the HVO production facility is included in the model.

About Inventory	
Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998

Method	The data are taken from RVF: ''Svensk avfallshantering 1990'', Malmö, November 1990.
Literature Reference	RVF: ''Svensk avfallshantering 1990'', Malmö, November 1990.
Notes	No information is given about the emissions of CO and hydrocarbons, though emissions of these substances occour. The lack of informaiton is due to the fact that the evidence in the investigation of the emissions are too small to allow any general conclutions about these emissions.

Flow Table and Specific Meta Data

QMetaData	Direction	FlowType	Substance	Quantity	Min	Max	Unit	Environment	Geography
	Input	Refined resource	Aluminium	1			kg	Technosphere	Sweden
	Output	Emission	Ash	1899			g	Air	Sweden
Method: Since it is difficult to say anything about the radical formation of the various materials, NOx formation has been assumed to be proportional to their heat content. This involves the assumption that the thermal NOx formation plays a more important role. Se notes. Notes: The emissions of NOx are more dependent on the technical aspects of inceneration than the composition of the material. NOx are invariably formed during inceneration. It may be formed from the nitrogen content of the fuel of the nitrogen in the combustion air. In the incineration of waste which has low contents of nitrogen, the formation of NOx mostly comes from the nitrogen in the air. The NOx is formed from the air in two different ways. 1. Immidiate NOx formation from the nitrogen in the air at the front of the frame due to hydrocarbon radicals from fuel. The amount is fairly small during lage-scale incineration and in most cases can be disregarded. 2. Thermal NOx formation starts at 900 degrees Celsius, but only becomes significant at 1200 degrees Celsius. The higher the temperature and the longer the flue gases remain in the high-temperature zone, the greater the NOx emissions. Refering to McKinsey & Company, Inc. ''Integrated substance chain management'' (and appendix); Association of the Dutch Chemical Industry (VNCI); Leidschendamm, The Netherlands; 1991.	Output	Emission	NOx	4.90			g	Air	
Method: The material-specific particulate emission depend on the ash content of each material. The residues consist of 10% fly ash, while 90% is bottom slag. The separation rate used for particulate is 99,6%. The figures have been desided through personal communication with Carl-Arne Pedersen and Christer Lundgren, Sävenäs waste heat plant, GRAAB, Göteborg	Output	Emission	Particulates	0.76			g	Air	
	Output	Product	Thermal energy	30.6			MJ	Technosphere	

About Inventory

Publication	RVF: ''Svensk avfallshantering 1990'', Malmö, November 1990. -- Data documented by: Maria Erixon and Sara Ågren, project employed at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Henrikke Baumann and Anne-Marie Tillman (responsible for the course material) and Ann-Christin Pålsson (responisble for classification of the dataset), Technical Environmental Planning, Chalmers University of Technology --
Intended User	A Life Cycle Assessment practi
General Purpose	The data set is part of a study about waste treatment.
Detailed Purpose	Exercise material in LCA course given at Teknisk Miljöplanering at Chalmers University of Technology, Sweden.
Commissioner	
Practitioner	Tillman, Anne-Marie - Technical Environmental Planning Chalmers University of Technology 412 96 Göteborg Sweden.
Reviewer	

Applicability	The data can be used, when one wants to estimate the emissions to air and the energy extracted, when 1 kg aluminium is incinerated at a thermal energy plant, that uses waste as fuel. The data are valid for Swedish conditions, but can be used as an approximation to other countries. One should though be aware of the fact that the situation in other countries may be very different and depending on this get one gets an unreliable result. The data are based on old sources and should therefore not be regarded as information describing the current situation. It is difficult to use the data in a correct way, because so little information is given about the system.
About Data	No information is given about the emissions of CO and hydrocarbons, though emissions of these substances occur. The lack of information is due to the fact that the evidence in the investigation of the emissions are too small to allow any general conclusions about these emissions.
Notes	

SPINE LCI dataset: Incineration of biological household waste. ESA-DBP

Administrative	
Finished	Y
Date Completed	2006-2007
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Incineration of biological household waste. ESA-DBP
Functional Unit	1 ton of biological household waste
Functional Unit Explanation	The functional unit is 1 ton of dry substance biological household waste.
Process Type	Gate to grave
Site	RenovaSävenäs, Sweden
Sector	Waste treatment
Owner	RenovaSävenäs, Sweden
Technical system description	The household waste is combusted in an oven, which produces steam that runs a turbine with a generator and a pressure condenser for production of electricity and district heating. The total combustion capacity is 59 tons of waste per hour. Moisture content in the waste is in average 32 %. The smoke and gases that are produced by the combustion are carried off via an exhaust steamboiler to a treatment plant including several steps. Translated excerpts from the report (see 'Publication'): ''The alternative to digestion of the waste is incineration in the power plant in Gothenburg. The tranpsort to the incineration plant ie executed with large lorries á 30 tons waste per each. At the plant heat and electricity are extracted from the incinerated waste. In this alternative case artificial fertilizer replaces the bio fertilizer and petrol and diesel replaces the vehicle gas.'' Processes included in the incineration system: - Incineration plant - Waste transport, one-way - Petrol in light vehicles - Diesel in heavy vehicles - Production of artificial fertilizer Processes not included in the incineration system: - Electricity use at the plant - Ashes and slag

	- Transport of artificila fertilizer - Use of chemicals This process is included in the system described in: Ljungkvist H, 2008, Miljö- och samhällsekonomisk analys av behandling av biologiskt avfall. Environmental Systems Analysis report 2008:1, Chalmers University of Technology, Gothenburg, Sweden Link to pdf (in Swedish): http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2008--1.pdf Other processes in the CPM Database also included in the above publication: 'Anaerobic digestion of biological household waste. ESA-DBP'

System Boundaries

Nature Boundary	Not applicable.
Time Boundary	The documentor makes a qualified guess that the data was produced in the years 2006-2007, based on information in the report.
Geographical Boundary	The incineration plant is located in Sävenäs, Gothenburg, Sweden Translated excerpts from the report (see 'Publication'): ''Only emissions form one-way transport are allocated to the incineration alternative, since the cars often have other commissions on the way back. One-way distance is 110 kilometers.''
Other Boundaries	Translated excerpts from the report (see 'Publication'): ''The alternative to digestion of the waste is incineration in the power plant in Gothenburg. The tranpsort to the incineration plant ie executed with large lorries á 30 tons waste per each. At the plant heat and electricity are extracted from the incinerated waste. In this alternative case artificial fertilizer replaces the bio fertilizer and petrol and diesel replaces the vehicle gas.'' Processes included in the incineration system: - Incineration plant - Waste tranport, one-way - Petrol in light vehicles - Diesel in heavy vehicles - Production of artificial fertilizer Processes not included in the incineration system: - Electricity use at the plant - Ashes and slag - Transport of artificila fertilizer - Use of chemicals
Allocations	Not applicable.
Systems Expansions	For comparison with the anaerobic digestion alternative emissions from produciton of artificial fertilizer and production of petrol and diesel are included.

About Inventory	
Publication	Ljungkvist H, 2008, Miljö- och samhällsekonomisk analys av behandling av biologiskt avfall. Environmental Systems Analysis report 2008:1, Chalmers University of Technology, Gothenburg, Sweden Link to pdf (in Swedish): http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2008--1.pdf
Intended User	LCA practitioners and employees at Ragn-Sells.
General Purpose	Master Thesis. Excerpt from the report (see 'Publication'): ''Biogas is a renewable fuel that can be extracted from anaerobic digestion of many different substrates, for example biological household waste. An alternative handling of the waste is to mix it with other wastes and incinerate it in a combined heat and power (CHP) plant. This study uses life cycle assessment to investigate which type of waste handling that is better from an environmental point of view, anaerobic digestion with biogas production or incineration. The results are based on a case study of a biogas production plant owned by the company Ragn-Sells in Vänersborg. The alternative is incineration at a CHP plant in Gothenburg.''
Detailed Purpose	These are the data for the combustion process.
Commissioner	Ragn-Sells - .
Practitioner	Ljungkvist, Hanna - .
Reviewer	Palme, Ulrika -
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries'.
About Data	Translated excerpts from the report (see 'Publication'): ''The tranpsort to the incineration plant ie executed with large lorries á 30 tons waste per each.'' ''Emission data from fertilizer production is based on LCA data from Berglund and Börjesson (2003).'' NB: Whole reference can be found in the publication. ''For emissions from the incineration plant, used data is from tables in Baumann and Tillman (2004) for incineration of biological household waste. In reality this waste is mixed with other fractions before incineration.'' NB: Whole reference can be found in the publication. The power plant produces its own electricity. ____ ESA Database Project. Years: 2009-2011. Documentation completed for this data set: YYYY-MM-DD Administering organisation: Chalmers University of Technology, the division of Environmental Systems Analysis. Financier: The Swedish Research Council. Documentor of data: Filippa Fuhrman (ESA. Review committee for documented data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).

Flow Data

General Activity QMetaData	
Date Conceived	1990
Data Type	Derived, unspecified
Represents	See 'Function'.
Method	The data are taken from RVF: ''Svensk avfallshantering 1990'', Malmö, November 1990.
Literature Reference	RVF: ''Svensk avfallshantering 1990'', Malmö, November 1990.
Notes	No information is given about the emissions of CO and hydrocarbons, though emissions of these substances occour. The lack of informaiton is due to the fact that the evidence in the investigation of the emissions are too small to allow any general conclutions about these emissions.

Flow Table and Specific Meta Data

QMetaData	***Direction***	***FlowType***	***Substance***	***Quantity***	***Min***	***Max***	***Unit***	***Environment***	***Geography***
Notes: Moisture content 15%	Input	Refined resource	Corrugated board	1			kg	Technosphere	Sweden
	Output	Emission	Ash	19.998			g	Air	Sweden
Method: Since it is difficult to say anything about the radical formation of the various materials, NOx formation has been assumed to be proportional to their heat content. This involves the assumption that the thermal NOx formation plays a more important role. Se notes. Notes: The emissions of NOx are more	Output	Emission	NOx	2.67			g	Air	

dependent on the technical aspects of inceneration than the composition of the material. NOx are invariably formed during inceneration. It may be formed from the nitrogen content of the fuel of the nitrogen in the combustion air. In the incineration of waste which has low contents of nitrogen, the formation of NOx mostly comes from the nitrogen in the air. The NOx is formed from the air in two different ways. 1. Immidiate NOx formation from the nitrogen in the air at the front of the frame due to hydrocarbon radicals from fuel. The amount is fairly small during lage-scale incineration and in most cases can be disregarded. 2. Thermal NOx formation starts at 900 degrees Celsius, but only becomes significant at 1200 degrees Celsius. The higher the temperature and the longer the flue gases remain in the high-temperature zone, the greater the NOx emissions. Refering to McKinsey & Company, Inc. ''Integrated substance chain management'' (and appendix); Association of the Dutch Chemical Industry (VNCI); Leidschendamm, The Netherlands; 1991.									
Method: The material-specific particulate emission depend on the ash content of each material. The residues consist of 10% fly ash, while 90% is bottom slag. The separation rate used for particulate is 99,6%. The figures have been desided through personal communication with Carl-Arne Pedersen and Christer Lundgren, Sävenäs waste heat plant, GRAAB, Göteborg	Output	Emission	Particulates	0.008			g	Air	
	Output	Product	Thermal energy	16.7			MJ	Technosphere

Applicability	The data can be used, when one wants to estimate the emissions to air and the energy extracted, when 1 kg corrugated board is incinerated at a thermal energy plant, that uses waste as fuel. The data are valid for Swedish conditions, but can be used as an approximation to other countries. One should though be aware of the fact that the situation in other countries may be very different and depending on this get one gets an unreliable result. The data are based on old sources and should therefore not be regarded as information describing the current situation. It is difficult to use the data in a correct way, because so little information is given about the system.
About Data	No information is given about the emissions of CO and hydrocarbons, though emissions of these substances occour. The lack of informaiton is due to the fact that the evidence in the investigation of the emissions are too small to allow any general conclutions about these emissions.

Method: The material-specific emission factor for CO2 has been calculated on the basis of elementary analysis.	Output	Emission	CO2	1407			g	Air	Sweden
Method: The material-specific emission factor for HCl has been calculated on the basis of elementary analysis.	Output	Emission	HCl	29.2			g	Air	Sweden
Method: Since it is difficult to say anything about the radical formation of the various materials, NOx formation has been assumed to be proportional to their heat content. This involves the assumption that the thermal NOx formation plays a more important role. Se notes. Notes: The emissions of NOx are more dependent on the technical aspects of inceneration than the composition of the material. NOx are invariably formed during inceneration. It may be formed from the nitrogen content of the fuel of the nitrogen in the combustion air. In the incineration of waste which has low contents of nitrogen, the formation of NOx mostly comes from the nitrogen in the air. The NOx is formed from the air in two different ways. 1. Immidiate NOx formation from the nitrogen in the air at the front of the frame due to hydrocarbon radicals from fuel. The amount is fairly small during lage-scale incineration and in most cases can be disregarded. 2. Thermal NOx formation starts at 900 degrees Celsius, but only becomes significant at 1200 degrees Celsius. The higher the temperature and the longer the flue gases remain in the high-temperature zone, the greater the NOx emissions. Refering to McKinsey & Company, Inc. ''Integrated substance chain management'' (and appendix); Association of the Dutch Chemical Industry (VNCI); Leidschendamm, The Netherlands; 1991.	Output	Emission	NOx	2.88			g	Air	
	Output	Product	Thermal energy	18			MJ	Technosphere

Publication	RVF: ''Svensk avfallshantering 1990'', Malmö, November 1990. -- Data documented by: Maria Erixon and Sara Ågren, project employed at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Henrikke Baumann and Anne-Marie Tillman (responsible for the course material) and Ann-Christin Pålsson (responisble for classification of the dataset), Technical Environmental Planning, Chalmers University of Technology --
Intended User	A Life Cycle Assessment practi
General Purpose	The data set is part of a study about waste treatment.

Detailed Purpose	Exercise material in LCA course given at Teknisk Miljöplanering at Chalmers University of Technology, Sweden.
Commissioner	
Practitioner	Tillman, Anne-Marie - Technical Environmental Planning Chalmers University of Technology 412 96 Göteborg Sweden.
Reviewer	
Applicability	The data can be used, when one wants to estimate the emissions to air and the energy extracted, when 1 kg PVC is incinerated at a thermal energy plant, that uses waste as fuel. The data are valid for Swedish conditions, but can be used as an approximation to other countries. One should though be aware of the fact that the situation in other countries may be very different and depending on this get one gets an unreliable result. The data are based on old sources and should therefore not be regarded as information describing the current situation. It is difficult to use the data in a correct way, because so little information is given about the system.
About Data	No information is given about the emissions of CO and hydrocarbons, though emissions of these substances occour. The lack of informaiton is due to the fact that the evidence in the investigation of the emissions are too small to allow any general conclutions about these emissions.

SPINE LCI dataset: Inductor assembly

Administrative	
Finished	Y
Date Completed	2000-03-13
Copyright	Ericsson
Availability	Official

Technical System	
Name	Inductor assembly
Functional Unit	One gram inductor intended for surface mounting
Functional Unit Explanation	The motivation for choosing this functional unit is: · Suitable unit to work with in an LCA of a private branch exchanges (a complicated telecom product) · Important component of the MD110 product system and many other electronic products. DESIGN These facts are based on Ericsson technical specification of the component. Ericsson product number: REG 707 0119/3 Ericsson description: Miniature chip choke Chokes are examples of components with the same electrical function as inductors and transformers. GENERAL Miniature chip choke intended for automatic mounting and all soldering methods. MECHANICAL DATA

	Design: The chip choke is flame retardant encapsulated with high-temperature resistant copper winding and a cube-shaped core made of ferrite. Terminals: Design 1, Silver plated solder terminals Design 2, Terminals with tin plated brass. Dimensions: Height: 4.5 mm, Length: 3.2 mm, Width: 3.2 mm Weight: app. 0,12 g
Process Type	Gate to gate
Site	Not relevant
Sector	Manufacturing
Owner	Not relevant
Technical system description	This activity includes the final assembly of an inductor. The activity is based on information acquired from one manufacturer. The description of the process is assumed to be general for this type of manufacture. The following process steps are included; 1. Core mounting 2. Epoxy-curing 3 Winding 4. Welding 5. Molding 6. Marking 7. Bending 8. Testing 9. Final control 10. Taping Details given: 1. Core mounting: Cores inserted into leadframe and fixed by adhesive (epoxy resin) emission negligible 3. Winding: 3 % of magnet wire recycled 4. Welding: Winding ends connected to the leads by ultrasonic welding 5. Molding: Abundant PPS is reused , scrapped PPS thermally decomposed 7. Bending: Abundant leadframe ist recycled 8. Testing: 100 %; scrap <1 % Additional information: Below is some additional information supplied by the component manufacturer. Our description of the component is a FR choke of type wound SMT choke. Chokes are similar to inductors. The annual production (97/98) was 25,000,000. In the factory also capacitors, other inductors and filters are produced. The general description is: Production of passive components with no environmental problems. Planned changes in production rate is that a second line with higher output for the component is in discussion.

System Boundaries

Nature Boundary	The emissions to air have nature as recipient. Each parameter mentioned by the component manufacturers has been studied. No parameter has deliberately been disregarded when environmental impact has been studied. Emissions to water and soil are excluded due to lack of data.
Time Boundary	1998 The answer from the manufacturer arrived in 1998 and they measured in 1998. The process technology used is most certainly the best available as the factory is located in western Germany and the company is well established.
Geographical Boundary	The technical system for this model is limited to the factory where the production takes place. The manufacturer is located in Germany.
Other Boundaries	Delimitation's to the system is the final step in the making of the inductor. The production of the subparts (e.g. Fe3O4, Copper magnet, CuSn6 and PPS) of the inductor is not included in this model. The transportation of them to the factory is not included. For interested parties who wish to include the transport figures given from the manufacturers, can find the figures in the section Applicability.

Allocations	The manufacturers have not described how the allocation has been made. We did not decide or have any suggestions on how the manufacturer should allocate in their factory. The electricity consumption per component is well ascertained by the manufacturer.
Systems Expansions	None.

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, unspecified
Represents	See 'Function'.
Method	The data that is presented is calculated based on information from one component manufacturer. The information from the manufacturer was acquired using a LCI data questionnaire. The average for each presented flow is calculated as follows: -The amount of each flow per functional unit is calculated for the component manufacturer In the information supplied by the manufacturer, they had indicated whether the data for each flow were measured, estimated or calculated. Below is a detailed account of the calculation procedure. Definition of variables: CMn: Component manufacturer number n. Myn: Materials, emission, waste, energy (y) given in component answer n. ACyn: Amount of material y in component, expressed in mg (or similar) by component manufacturer n Wn: Weight of one piece of component, expressed in mg (or similar) by component manufacturer n. Nyn: The flow y expressed per functional unit from manufacturer n. Step 1. For CM1 sum AC1+.+.ACn Step 2: The sum AC11+.+.ACyn = W1 Step 3: Divide all flows between M11...M1n by W1 --> N11...N1n Step 4: Repeat Step 1 to 3 for all component manufacturers and for each flow.
Literature Reference	RVF: ''Svensk avfallshantering 1990'', Malmö, November 1990.
Notes	No information is given about the emissions of CO and hydrocarbons, though emissions of these substances occour. The lack of informaiton is due to the fact that the evidence in the investigation of the emissions are too small to allow any general conclutions about these emissions.

About Inventory

	Publication	Not available -- Data documented by: Anders Andrae, Ericsson Business Networks AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
	Intended User	The intended use for this LCI
	General Purpose	The general purpose with this LCI model was for application in a LCA project at Ericsson Business Networks. The main goal of the study is; to compare the potential environmental impacts associated with an old (BC 8) and a new model (BC 10) of a private branch exchange (PBX) system, namely the MD110 system, and an additional objective is to include comparisons between different stages of the life cycle (e.g. manufacturing, use and end of life) of the system. The system, PBX MD110, is designed, developed and delivered by Ericsson Enterprise Systems AB. Life-Cycle Assessment methodology (following the ISO14040 standards for LCAs) will be used to determine the environmental impacts. The main purpose of the study for Ericsson is; - to learn, test and evaluate the LCA-methodology as a tool for assessing environmental improvement options in the product design process, and to make up concrete product guidelines regarding design for environment (DfE) and - to evaluate environmental aspects in new design. The relative importance for different life cycle stages may also be an important input in the internal work with an Environmental Management System for Ericsson Enterprise Systems. Another purpose of the study is; to collect and qualify data from suppliers and literature in order to build up a database for this and future LCA activities and within the project, it is also intended to analyse the possibilities to use the study as a base for future work regarding a type III ecolabeling project within Ericsson. The intended audience of the report from the project is; Ericsson's personnel: project management, system management, design, marketing and sales organisation, and thus also (in an extracted version) the Ericsson customers.
	Detailed Purpose	Map an inductor assembly process from an environmental standpoint in a structured procedure. The purpose of the project was to collect resource consumption data and emission data connected with the final assembly of inductors and resembling components in our telecom products. The usage for this set of data is life cycle assessments where inductors intended for surface mounting are part of the studied system. Note: This model is one of in total eighteen models compiled at Ericsson, describing 16 component groups in the PBX. The division into component groups is based on structural resemblance, electrical function and material contents of the different components. -- Below is a list of the component groups and corresponding models that have been compiled: 1. Cables - Model: Cable assembly 2. Capacitors and filters; hole mounted devices - Model: Capacitor for hole mounting assembly 3. Capacitors; surface mounted devices - Model: Capacitor for surface mounting assembly 4. Connectors and holders - Model: Connector assembly 5. Diodes - Model: Diode wafer production and assembly 6. Display units and indicators - Model: Liquid crystal display assembly 7. Microcircuits, oscillators, quartz crystal units and delay lines (2 models) - Models: 1. Integrated circuit capsule assembly and 2. Si wafer production and Si wafer processing for integrated circuits (these models are interlinked) 8. Other - Model: ''Other'' electronic component assembly 9. Potentiometers - Model: Potentiometer assembly 10. Printed boards - Model: Printed board assembly 11. Relays - Model: Relay assembly

	12. Resistor networks - Model: Resistor network assembly 13. Resistors, varistors and thermistors; hole mounted devices - Model: Resistor for hole mounting assembly 14. Resistors; surface mounted devices - Model: Resistor for surface mounting assembly 15. Transformers and inductors - Model: Inductor assembly 16. Transistors and opto couplers (2 models) - Models: 1. Transistor assembly and 2. Si wafer production and Si wafer processing for transistors (these models are interlinked)
Commissioner	- Ericsson .

Reviewer	Pålsson, Ann-Christin - CPM Chalmers University of Technology S-412 96 Göteborg Sweden
Applicability	This set of data can be applied to inductors intended for hole mounting in electronic equipment if you know how much the inductors weigh. The model is also intended to be representative for transformers in electronic equipment. -- Transports. -- Here follows a more detailed description of transports of materials and components to the respective manufacturer factories. These transports are not included in the model. CM1 = Component manufacturer one The calculation for all modes of transport is done like this: First the total transportation work per functional unit is calculated for each included component manufacturer. Then the total transportation is summed and divided by the number of included component manufacturers. This gives the average value for transportation by each mode of transport. -- Truck transportation: -- Weight of component: 0.166 g Fe3O4 with weight 0.045 g is transported 1300 km by truck, i.e. 0.045 * 1300 km, Copper magnet 0.04 * 1500, PPS 0.35 * 2000, (CuSn6) 0.012 * 2700 Solder 0.003 * 1700 The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives: 856.9 gkm/0.166 g = 5162 gkm/g -- Boat transportation: -- Fe3O4 with weight 0.045 g is transported 20,000 km by boat, i.e. 0.045 * 20,000 km, Copper magnet 0.04 * 500, PPS 0.35 * 500, (CuSn6) 0.012 * 500 Solder 0.003 * 500 The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives: 1102.5 / 0.166 = 6641.57 gkm /g
About Data	The data is based on information from one German manufacturer. The information was gathered using a life cycle inventory questionnaire. The figures in the original answer from the manufacturer should all have a special tag telling if the value has been calculated, measured or estimated or a combination of two or three of them. Ericsson specifically told the manufacturers to do so. The result is that approximately 78 % of the flows stated by the manufacturer were only calculated and 22 % were only estimated. The outline of the LCI data questionnaire that was used in the inventory follows below. No limitations or specifications were set for which substances they had to account -- LCI data questionnaire -- Transport description: Material type, Used weight of Material (g)/functional unit, Transport by road of Material (km), Transport by boat of Material (km), Transport by rail of Material (km). We here only asked for flows exceeded 2% by weight of the material declaration of the

	component. Additional information was also asked for and here some manufacturers mentioned they had aeroplane transport instead of some of the other transport modes. Process description. Description of the entire production at the plant/site and a technical description of the plant production. Description of the production line of the studied product. Flow chart of process steps for production of the studied product. Technical description of the production line. A very short description of each unit operation. Data quality. For every figure you give, give an account on how you gathered it. C = calculated, E = estimated, M = measured. General LCA-related information on the production system (Allocation procedures, system boundaries, etc.). Additional information. (E.g. planned changes in production rate) Material, components and natural resource input, etc. We told them to express data in amount per functional unit. Name of material, component or resource. Used amount (mg). Amount In Product (mg). Additional information Energy-ware input Energy -ware source. Quantity/functional unit. Unit. Energy-ware supplier, production sites (address). Technical System	
Name	Integrated circuit capsule assembly
Functional Unit	One gram of integrated circuit capsule.
Functional Unit Explanation	The motivation for choosing this functional unit is: · suitable unit to work with in an LCA of a private branch exchange (a complicated telecom product) · important component of the MD110 product system and many other electronic products. DESIGN

	The answers from component manufacturer one (CM1) and component manufacturer three (CM3) are for exactly the same type of component. Component manufacturer one (CM2) produces protype capsules of an other kind of IC. These facts are based on Ericsson technical specification of the component. Ericsson product number: RYT 304 0164/C Ericsson description of the integrated circuit capsule: Microcircuit, HCMOS, 8 bit shift register General technical specification The circuit consists of an eight bit parallel-out serial shift register. All outputs standard type. Representative type: 74HC164 Small out line package (SO) with 14 terminals and 4.90 mm nominal width. Dimensions: capsule size SOP14 Weight: about 0.135 grams Silicon chip area: 2.3 mm2 The size of the circuits varies depending on chip size, and number of terminals of the leadframe. Large importance has also the type of capsule. Important measures for the capsule type Small Outline Package (SOP) and Plastic Lead Chip Carrier (PLCC) are in this range: Total package height (mm): 4,19 - 5,08 (for PLCC) Terminal thickness (mm): 0,19-0,32 (for SOP) Total body lenght including terminals (mm): 9,77-30,36 (for PLCC) Total package width including terminals (mm): 5,8-10,65 (for SOP) Total number of terminals (mm): 20-84 (for PLCC)
Process Type	Gate to gate
Site	Not relevant
Sector	Manufacturing
Owner	Not relevant
Technical system description	This activity includes the final encapsulation assembly of an integrated circuit capsule. The activity is an average based on information acquired from three manufacturers. The description of the process is supplied by manufacturer one, but is assumed to be general for this type of manufacture. The following process steps are included; 1. Wafer Mounting 2. Wafer Sawing 3. Die Attach (die bonding onto a leadframe) 4. Snap Cure 5. Wire Bonding 6. Molding 7. Post Mold Cure 8. Deflashing 9. Plating (Solder- or tin) 10. Cropping&Laser Marking 11. Testing 12. Tape & Reel 13. Labelling&Packing No detailed description was given by manufacturer one, two or three. The transports between the wafer fab and the final capsule production are not included.

System Boundaries	
Nature Boundary	The emissions to air and water have nature as recipient. Each parameter mentioned by the component manufacturers has been studied. No parameter has deliberately been disregarded when environmental impacts have been studied. Included component manufacturers have not specified the same parameters. In the cases where only one manufacturer has stated a parameter this has been used.

Time Boundary	1997-1998 The information from CM1 and CM2 is from 1997 and the answer from the manufacturer three (CM3) arrived in 1998 and they measured in 1998. The process technology used is most certainly the best available as the factories are located in the Netherlands, Sweden and Malaysia and the companies are well established.
Geographical Boundary	The technical system for this model is limited to the factory where the production takes place. The manufacturers included in the average are located in the Netherlands, Sweden and Malaysia.
Other Boundaries	Delimitations to the system is the final encapsulation assembly of an integrated circuit (IC). The production of the sub-components (e.g. lead frame, Au-wire) needed to produce the final IC is not included. The transportation of them to the factory is not included. For interested parties who wish to include the transport figures given from the manufacturers, can find the figures in the section Applicability.
Allocations	The manufacturers have not described how the allocation has been made. We did not decide or have any suggestions on how the manufacturer should allocate in their factory.
Systems Expansions	None.

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, unspecified
Represents	See 'Function'.
Method	The data that are presented are calculated as a average based on information from three component manufacturers. The information from the manufacturers was acquired using a LCI data questionnaire. The average for each presented flow is calculated as follows: - First the amount of each flow per functional unit is calculated for each component manufacturer - Then the calculated amount for each component manufacturer is summed for each unique flow and divided by the number of included component manufacturers In the information supplied by the manufacturer, they had indicated whether the data for each flow were measured, estimated or calculated. Below is a detailed account of the calculation procedure. Definition of variables: CMn: Component manufacturer number n. Myn: Materials, emission, waste, energy (y) given in component answer n. ACyn: Amount of material y in component, expressed in mg (or similar) by component manufacturer n Wn: Weight of one piece of component, expressed in mg (or similar) by component manufacturer n. Nyn: The flow y expressed per functional unit from manufacturer n. Step 1. For CM1 sum AC1+..+.ACn Step 2: The sum AC11+..+.ACyn = W1 Step 3: Divide all flows between M11...M1n by W1 --> N11...N1n Step 4: Repeat Step 1 to 3 for all component manufacturers and for each flow. Step 5: Sum N1n+..Nyn and divide by the number of terms for each unique flow.(material input, emission etc.) An average calculation like above of up to three answers was made.
Literature Reference	Literaturreferences or contact persons aided the data compilation:. Jens Malmodin, Ericsson Radio Systems
Notes	No information is given about the emissions of CO and hydrocarbons, though emissions of these substances occour. The lack of informaiton is due to the fact that the evidence in the investigation of the emissions are too small to allow any general conclutions about these emissions.

Date concieved: 1998 Data type: Derived, unspecified Method: CM1: 129 mg/g CM3: 237,8 mg/g (CM1+ CM3)/2 = 183,4 mg/g This is an average value based on two sources.	Output	Residue	Sn/Pb plating	0.1834			g	Technosphere	

About Inventory

Publication	Not available -- Data documented by: Anders Andrae, Ericsson Business Networks AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The intended use for this LCI
General Purpose	The general purpose with this LCI model was for application in a LCA project at Ericsson Business Networks. The main goal of the study is; to compare the potential environmental impacts associated with an old (BC 8) and a new model (BC 10) of a private branch exchange (PBX) system, namely the MD110 system, and an additional objective is to include comparisons between different stages of the life cycle (e.g. manufacturing, use and end of life) of the system. The system, PBX MD110, is designed, developed and delivered by Ericsson Enterprise Systems AB. Life-Cycle Assessment methodology (following the ISO14040 standards for LCAs) will be used to determine the environmental impacts. The main purpose of the study for Ericsson is; - to learn, test and evaluate the LCA-methodology as a tool for assessing environmental improvement options in the product design process, and to make up concrete product guidelines regarding design for environment (DfE) and - to evaluate environmental aspects in new design. The relative importance for different life cycle stages may also be an important input in the internal work with an Environmental Management System for Ericsson Enterprise Systems. Another purpose of the study is; to collect and qualify data from suppliers and literature in order to build up a database for this and future LCA activities and within the project, it is also intended to analyse the possibilities to use the study as a base for future work regarding a type III ecolabeling project within Ericsson. The intended audience of the report from the project is; Ericsson's personnel: project management, system management, design, marketing and sales organisation, and thus also (in an extracted version) the Ericsson customers.
Detailed Purpose	Map an IC assembly process from an environmental standpoint in a structured procedure. The purpose of the project was to collect resource consumption data and emission data connected with the final assembly of microcircuits and resembling components in our telecom products. The usage for this set of data are life cycle assessments where microcircuits (integrated circuits) are part of the studied system. Note: This model is one of in total eighteen models compiled at Ericsson, describing 16 component groups in the PBX. The division into component groups is based on structural resemblance, electrical function and material contents of the different components. -- Below is a list of the component groups and corresponding models that have been compiled: 1. Cables - Model: Cable assembly 2. Capacitors and filters; hole mounted devices - Model: Capacitor for hole mounting assembly 3. Capacitors; surface mounted devices - Model: Capacitor for surface mounting assembly 4. Connectors and holders - Model: Connector assembly 5. Diodes - Model: Diode wafer production and assembly 6. Display units and indicators - Model: Liquid crystal display assembly 7. Microcircuits, oscillators, quartz crystal units and delay lines (2 models) - Models: 1. Integrated circuit capsule assembly and 2. Si wafer production and Si wafer processing for integrated circuits (these models are interlinked) 8. Other - Model: ''Other'' electronic component assembly 9. Potentiometers - Model: Potentiometer assembly 10. Printed boards - Model: Printed board assembly 11. Relays - Model: Relay assembly

	12. Resistor networks - Model: Resistor network assembly 13. Resistors, varistors and thermistors; hole mounted devices - Model: Resistor for hole mounting assembly 14. Resistors; surface mounted devices - Model: Resistor for surface mounting assembly 15. Transformers and inductors - Model: Inductor assembly 16. Transistors and opto couplers (2 models) - Models: 1. Transistor assembly and 2. Si wafer production and Si wafer processing for transistors (these models are interlinked)
Commissioner	- Ericsson .
Practitioner	Andrae, Anders - Ericsson Business Networks AB Augustendalsvägen 21 S-131 89 Stockholm Office: Nacka Strand .
Reviewer	Pålsson, Ann-Christin - CPM Chalmers University of Technology S-412 96 Göteborg Sweden
Applicability	This set of data can be applied to integrated circuits (i.e. IC´s) in electronic equipment if you know the total weight of the IC´s. The model is intended to be representative for microcircuits, oscillators, quartz crystal units and delay lines in electronic equipment. -- Transports-- Here follows a more detailed description of transports of materials and components to the respective manufacturer factories. These transports are not included in the model. CM1 = Component manufacturer one The calculation for all modes of transport is done like this: First the total transportation work per functional unit is calculated for each included component manufacturer. Then the total transportation is summed and divided by the number of included component manufacturers. This gives the average value for transportation by each mode of transport. -- Truck transportation: -- Component manufacturer one (CM3): Weight of component: 0.119 g Silicon die with weight 0.0015 g is transported 10 km by road i.e. 0.0015 g*10 km, Lead frame 0.05 g*10 km, Wires 0.0025 g*350 km, Filled epoxy resin 0.062 g*350 km and Solder 0.006 g*250 km. The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives: 24.59 gkm/0.119 g = 206.63 gkm/g -- Airplane transportation: -- Silicon die with weight 0.0015 g is transported 10000 km by air i.e. 0.0015 g*10000 km This gives: 15 gkm/0.119 g = 126.05 gkm/g
About Data	The data is based on information from three manufacturers. The information was gathered using a life cycle inventory questionnaire (CM2 and CM3) and brochures (CM1). CM1 answered with a brochure when asked to fill in the questionnaire. All flows are not average values and where there were only one manufacturer stating a certain flow, this one was chosen in the model. Of the flows about little more than 85 % are not average values.The flows for Energy input of Electricity, Raw material inputs of PP and Sn/Pb plating and Waste output of Sn/Pb plating are average values. In specific QMetaData for each flow, we have indicated specifically for each flow how many manufacturers have been included. The figures in the original answer from the manufacturers all have a special tag telling if the value has been calculated, measured or estimated or a combination of two or three of them. Ericsson specifically told the manufacturers to do so. Only in one source (CM3) this information was given. The result is that approximately 35 % of the flows were only calculated and 65 % were only estimated. All flows are not average values and where there were only one manufacturer stating a certain flow, this one was chosen in the model.

	These flows were asked for and no limitations were set for which substances for which they had to account. Transport description: Material type, Used weight of Material (g)/functional unit, Transport by road of Material (km), Transport by boat of Material (km), Transport by rail of Material (km). We here only asked for flows exceeded 2% by weight of the material declaration of the component. Additional information was also asked for and here some manufacturers mentioned they had aeroplane transport instead of some of the other transport modes.´ Process description. Description of the entire production at the plant/site and a technical description of the plant production. Description of the production line of the studied product. Flow chart of process steps for production of the studied product. Technical description of the production line. A very short description of each unit operation. Data quality. For every figure you give, give an account on how you gatherd it. C = calculated, E = estimated, M = measured. General LCA-related information on the production system (Allocation procedures, system boundaries, etc.). Additional information. (e.g. planned changes in production rate) Material, components and natural resource input, etc. We told them to express data in amount per functional unit. Name of material, component or resource. Used amount(mg). Amount In Product(mg). Additional information Energy-ware input Energy -ware source. Quantity/functional unit. Unit. Energy-ware supplier, production site (address). Suppliers of transport (address). Additional information. Emissions. Emissions to air. Indicate whether emissions from energy use are included in the data. Name of emission to air. Emission to air/functional unit (mg). Additional information. Emissions to water. Indicate if data describes emissions going to external purification plant or directly to recipient. Name of emission to water. Emission to water/functional unit (mg). Additional information. Emissions to soil. Name of emission to soil. Emission to soil/functional unit (mg). Additional information. Waste. Name of waste. Waste/functional unit (mg). Recycled/functional unit (mg). Additional information.

SPINE LCI dataset: Inventory of Volvo painting plant, TB4

Administrative	
Finished	Y
Date Completed	1996-10-21
Copyright	Chalmers University of Technology
Availability	Public.

Technical System	
Name	Inventory of Volvo painting plant, TB4
Functional Unit	''one produced coach at TB4 during 1994''

Functional Unit Explanation	A ''coach'' in this report is a coach from the Volvo 800- or 900-series. TB4 is one of Volvo Car Corporation's painting plant.
Process Type	Gate to gate
Site	Torslanda (Gothenburg)
Sector	Manufacturing
Owner	Torslanda (Gothenburg)
Technical system description	Technology descriptor: In this study, an inventory is performed on the painting process for Volvo Car Corporation's painting plant in Torslanda (Gothenburg), TB4. The following processes are done in TB4: filling, surface coatings, waste treatment, including touch-up of coatings and energy production. Detailed description follows below. Technical content and functionality: FILLING - Before the coach is coated, an undercoating of the chassis is done as a stone-protective device. Next, there is a finish grinding before the first coating is applied. Finish grinding is done to give the coach a smoother surface. The coach is washed and goes through a water-drying furnace. SURFACE COATING - Three layers of coating is applied on each coach: filler-, clear- and base coating. First the filler coating is applied as a protection layer. Thereafter the base coat is applied which contains the colour pigment. Finally a layer of clear coat is applied as a top protection layer. Filler coat, clear coat and base coat-solid are applied with a rotating decompositioner that rotates very fast and thereby finely disperse the paint. 80-85% of the colour sticks to the coach, the rest is removed with the water in the air cleaner, the so-called curtain water and goes out of the system as sludge. The base coat-metallic is applied in two layers. The first is applied with a rotating decompositioner. The second layer is applied with an air sprayer that uses compressed air to finely disperse the paint. Only 40-45% of the paint sticks to the coach. It gives a different nuance using two methods to apply the base coat-metallic, compared to using only the rotating decompositioner. Every layer of coating is preceded and followed by heating, cooling and coat control. The air-heating furnace is powered either by natural gas or by electricity. The hardening furnace that follows after the filler- and clear coating steps have a temperature of 130° C. The IR-dryer follows the base coating step. It consists of one IR-part (radiation dryer) and one pre-dryer; together they expel the water out of the coat-dispersion. In this step the temperature is about 80° C. After the washing, the coach is drained from water and then goes through a water-dryer (approximately 100-120° C). After every furnace there is a cooler, where the coach is cooled with air to room temperature. In between each coating the coach passes through a furnace, followed by a cooling step and finally a washing step. WASTE TREATMENT - In the coating boxes there is a lattice floor. The air in the boxes is sucked down the floor and goes through the water, which is under the lattice. The colour particles are dispersed in the water and give rise to sludge together with sludge chemicals. The air is cleaned further if the coating is containing solvents. The final cleaning of air, containing solvents, is done in the sand beds outside TB4, which gives CO_2 emissions. ENERGY PRODUCTION - TB4's energy central, TB5, is accounted for because its only purpose is to supply TB4 with energy. Energy sources in a descending order are electricity, natural gas, and district heating. Electricity: Except for the process itself and general use (for example general lighting), refrigerating machines and compressors are powered with electricity. District heating: The system includes a humidifier that uses district heating. Natural gas: TB5 has a natural gas driven hot water boiler.

System Boundaries

Nature Boundary	The selection of parameters was based on parameters from Volvo Car Corp.'s Environmental Report of 1994.
Time Boundary	The data was collected for 1994, unless other is mentioned, and one should consider some change in process steps etc. as times goes. The figures for energy application and emissions are from 1995, but have been weighted against quantities from 1994.
Geographical Boundary	Sweden
Other Boundaries	Downstream the boundary is set to that one painted coach, solvents to recycling, sludge, paint residues and discharge to air and water are outflows from TB4. Only sludge and paint residues are accounted for as waste (solvents are recycled). Excluded subsystems: The material- and energy application for the point improvement is assumed to be negligible in comparison with the total consumption and is not included. The heat requirement in TB4 is mainly covered with waste heat from Preem Refineries Corporation. Waste heat produced at Preem Refineries Corp. is outside the system

	boundaries of this study. Complementary combustion of natural gas is done in a common Volvo energy central, TD. (The discharge from the combustion of natural gas in TD is separately accounted for in the report 1996:9, Technical Environmental Planning, but has not been included in this activity). No transportations are accounted for in this documentation, only in Report 1996:9, Technical Environmental Planning. Excluded flows: Waste, such as packing material from smaller paint buckets etc., is not included since it's supposed to have a small environmental load compared to other flows. The production capital has no part in the study.
Allocations	Not applicable.
Systems Expansions	Not applicable.

Date concieved: 1995 Data type: Unspecified Method: The consumption of sealant was given by Dejan Nestarovic, Volvo Car Corporation. The sealant figures	Input	Refined resource	Sealants	4.15			kg	Technosphere	

are budgeted figures based on the consumption of 1995. Notes: Sealants = sealants based on PVC. Manufactured outside of Volvo.										
Date concieved: 1994 Data type: Unspecified Method: Information on sludge chemicals derives from Nils Malmbro, Volvo Car Corporation. Notes: Sludge chemicals = Maintenance chemicals for sprayboot systems.	Input	Refined resource	Sludge chemicals	1.7			kg	Technosphere		
Date concieved: 1994 Data type: Unspecified Method: EMI, a database at Volvo Car Corp. Notes: Solvents = 3,23 kg recycled solvents (Recycling outside of Volvo and then brought back to the system) & 0,92 kg produced solvents (Manufactured outside of Volvo).	Input	Refined resource	Solvents	4.15			kg	Technosphere		
Date concieved: 1994 Data type: Unspecified Method: EMI, a database at Volvo Car Corp. Notes: Manufactured outside of Volvo.	Input	Refined resource	Underbody paste	1.06			kg	Technosphere		
Date concieved: 1994 Data type: Unspecified Method: Data for the emissions was collected from the environmental report and therefore follows the data quality requirements by authorities. Notes: Emission from the energy demand for TB4/TB5.	Output	Emission	CO2	92			kg	Urban air		
Date concieved: 1994 Data type: Unspecified Method: Data for the emissions was collected from the environmental report and therefore follows the data quality requirements by authorities. Notes: Emission from the energy demand for TB4/TB5.	Output	Emission	Dust	0.00005		0.00005	kg	Urban air		
Date concieved: 1994 Data type: Calculated Method: Data for the emissions was collected from the environmental report and therefore follows the data quality requirements by authorities. Notes: Emission from the energy demand for TB4/TB5. Due to a breakdown in 1994 an estimated value based on the emissions for 1995 is used .	Output	Emission	HCFC-22	0.001			kg	Urban air		
Date concieved: 1994 Data type: Unspecified Method: Data for the emissions was collected from the environmental report and therefore follows the data quality requirements by authorities. Notes: Emission from the energy demand for TB4/TB5.	Output	Emission	NOx	0.2008			kg	Urban air		
Date concieved: 1994 Data type: Unspecified Method: Data for the emissions was collected from the environmental report and therefore follows the data quality requirements by authorities. Notes: Emission from the energy demand for TB4/TB5.	Output	Emission	Solvents	1.6			kg	Urban air		
Date concieved: 1994 Data type: Unspecified Method: Based on functional unit.	Output	Product	Painted coach	1			pce	Technosphere		
Date concieved: 1994 Data type: Unspecified Method: EMI, a database at Volvo Car Corp. Notes: Combustible waste.	Output	Residue	Paint residue	0.54			kg	Technosphere		
Date concieved: 1994 Data type: Unspecified Method: The amount of sludge was collected from Volvo Car Corporation's	Output	Residue	Paint sludge	4.54			kg	Technosphere		

Environmental Report of 1994. Notes: The sludge is combustible waste.									
Date concieved: 1994 Data type: Unspecified Method: EMI, a database at Volvo Car Corp. Notes: The unpure solvent is sent for recycling. 0,54 kg of that is paint residues wich is combustible waste. The rest (the pure solvent) is recycled back to the system, see ''Solvents''.	Output	Residue	Solvents, unpure	2.86			kg	Technosphere	

About Inventory

Publication	Elisabeth Andersson, Selection out of ''Inventering samt miljovardering av TB4, Volvo Personvagnars malerifabrik i Goteborg'', Report 1996:9, MSc thesis. Technical Environmental Planning, Chalmers University of Technology Göteborg, Sweden Data documented by: Dan Wahlström, Volvo Technological Development Corporation; Dept. of Environmental Science. Data reviewed by: Elisabeth Andersson and David Weiner, Volvo Technological Development Corporation; Dept. of Environmental Science. Documentation reviewed by: Ann-Christin Pålsson, CPM.
Intended User	LCA practitioners.
General Purpose	There has been some interest in performing a life cycle assessment of the painting process, especially since purification technique requires a great amount of energy.
Detailed Purpose	Perform an inventory of TB4. The Report (Report 1996:9, MSc thesis. Technical Environmental Planning, Chalmers University of Technology Göteborg, Sweden) which this data is based on, further follows in- and out-flows to/from TB4, but is not accounted for in this documentation.
Commissioner	Nevén, Carl-Otto - Volvo Car Corporation .
Practitioner	Andersson, Elisabeth - Volvo Technological Development Corp. Departement of Environmental Science .
Reviewer	Holmberg, Micaela - Volvo Technological Development Corp. Department of Environmental Science
Applicability	This documentation is based on a report (see Publication) which further follows in- and out-flows to/from TB4. All the data from the report has not been considered as relevant and is therefore not included in the documentation. The figures for the process changes as time goes, but it was considered a modern process in 1994 and the technique has not changed a lot. The environmental load for coating a coach is considered to be high, compared to other coating processes and therefore it could, in some cases, be used as a reference scenario.The figures could be used as a comparison with similiar coating processes. Only the production of some of the materials have been considered in the original report. Due to the great amount of chemical products that are used in TB4, only one or a couple of products of sealant, underbody pastes, fillers, base coats (both metallic and solid) and clear coats have been followed to the supplier (these flows are not followed and included in this data documentation, see Publication). The inventory data for the products that were used the most was collected and used in the valuation step as approximate values for similar products.
About Data	Data for sealants are approximated from the environmental report of 1995 to values for 1994. This is assumed not to have a great impact on the data quality, due to the large flows. Complementary information for the documentation of data, which were not available in the original report, has been retrieved from the author of the report, see Publication.
Notes	-

SPINE LCI dataset: Ireland, electricity generation mix 1998

Administrative	
Finished	Y
Date Completed	2001-01-31
Copyright	IEA
Availability	Public

Technical System	
Name	Ireland, electricity generation mix 1998
Functional Unit	Total electricity produced during 1998
Functional Unit Explanation	The electricity mix refer to the total amount of electricity generated by different power sources expressed in GWh during the year 1998.
Process Type	Unit operation
Site	Ireland
Sector	Energyware
Owner	Ireland
Technical system description	The generation of electricity with different power generating systems in Ireland during the year 1998.

System Boundaries	
Nature Boundary	Not applicable, since the data only refer to the electricity generation mix. The environmental load for generation of electricity is not included.
Time Boundary	The data refer to 1998.
Geographical Boundary	Only electricity produced in Australia is considered. Import or export of electricity is not included.
Other Boundaries	-
Allocations	Not applicable
Systems Expansions	Not applicable

Flow Data	
General Activity QMetaData	
Date Conceived	1998
Data Type	Derived, statistics
Represents	See 'Function'.
Method	The data are collected from IEA Statistics.
Literature Reference	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8, page II.300.
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

About Inventory

Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. --- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden ---
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998

	New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998
About Data	
Notes	-- --- Changes made to the data set after publishing in SPINE@CPM--- >>> 22 October 2001: <<< Changes made by Ann-Christin Pålsson, CPM: The total electricity production have been corrected from 9 056 977 GWh to 20 881 GWh according to the original report. The error was identified and reported by Gunnar Mattson, ABB Corporate Research.

SPINE LCI dataset: Jet plane, A 300-B4, 1200 km

Administrative	
Finished	Y
Date Completed	1999 - 12
Copyright	NTM
Availability	Public

Technical System	
Name	Jet plane, A 300-B4, 1200 km
Functional Unit	1 tonkm, 75 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 km calculated for 1200 km flight distance and an average utilisation level equivalent to 75 % of the aircrafts maximum payload capacity.
Process Type	Gate to gate
Site	Sweden
Sector	Air transport
Owner	Sweden
Technical system description	Operation of jet plane, type Airbus A 300-B4 with 2 engines Rolls Royce RB211-524, 1200 km, European flight, with 8 minutes of taxiing and landing run (3 min. in and 5 min. out). This is a larger plane, with a capacity of approximately 270 passengers in a passenger version. The plane presented here, however, is strictly a freight version which seats no passengers. Utilisation level is set to 75% for the medium quantity, 100% for ''min'' and 50% for ''max''. Fuel: Jet-A1. Takeoff Weight (TOW): 170 tons. Speed (cruise): 897 km/h. Maximum payload 45 000 kg.

System Boundaries	
Nature Boundary	Regulated missions to air from combustion of the fuel are included. The parameters that are presented are: - Regulated emissions for diesel engines:NOx, HC, Particles and CO - Fuel regulated: SO_2 - Tax regulated CO_2 Other environmental impacts, e.g., diffuse emissions to air, emissions to water and ground, noise, encroachment, from the operation of the aircraft are not included.
Time Boundary	The data represents aircrafts in use in 2000.
Geographical Boundary	Data is based on Swedish and European conditions.
Other Boundaries	The distance chosen is 1200 km, which is a typical distance for domestic goods transport flights in Sweden. The medium quantity implies a utilisation level of 75% , ''min'' implies a utilisation level of 100% and ''max'' 50%. Parameters not considered: External conditions i.e. climate etc. Maintenance level of the aircraft. Excluded subsystems: Precombustion i.e. production and distribution of fuels Maintanence and aftertreatment of the aircraft Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	
Data Type	Derived, unspecified
Represents	NTM
Method	For the calculation of emissions from the jet plane (Airbus A 300-B4), the flight simulation method of the Aerotechnical Research Station (FFA) has been used. FFA has used a software tool ''PIANO'', developed for studies of aircraft design. The tool contains a database with aerodynamical data for different aircrafts and engines. The emission data is from ICAO emission database (ICAO,1995). The calculations in PIANO is calibrated after results from the EU-project AEROCERT (Näs P, 1998) in which samples from real life flights has been analysed. The taxiing and landing run time chosen is 8 minutes (3 min. in, 5 min. out). Taxiing and loading run time depends mainly on the airport. The medium quantity implies a utilisation level of 75% of the aircrafts maximum payload capacity , ''min'' implies a utilisation level of 100% and ''max'' 50%.

About Inventory

Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.

Applicability	The emissions vary considerably between different types of aircraft and engine combinations. Thus, the emission data given in this context are only applicable to the specific type of aircraft and distances of this example. Provided that the plane types presented in this context are representative for their categories (size and age), the figures may be used for estimations of total emissions from a certain traffic volume. The total amount of emissions depends on a number of parameters of which the most important are starting weight and transportation distance. The longer the distance, the higher the emissions per flight, but lower per tonkm, since take-off and landing always have to take place in a flight. The distance chosen is 1200 km, which is a typical distance for flights for goods transport in Europe. The aircraft presented is a version that carries only goods. It is commonly used for goods transport in Sweden and in Europe. It is a large jet with 2 engines and in a passenger version it would carry almost 270 passengers. The taxiing and landing run time chosen is 8 minutes (3 min. in, 5 min. out). Taxiing and loading run time depends mainly on the airport. The medium quantity implies a utilisation level of 75% , ''min'' implies a utilisation level of 100% and ''max'' 50%. For calculations of emissions from flights of other distances than the ones given, the following relations can be used. They apply to flights of distances between 600 - 1200 km, with Airbus A 300-B4. Total emissions = Constant emission (kg) + Variable emission (kg/km) * distance (km) 50% payload: Constant emission CO2=2171 NOX=11,1 HC=0,34 CO=6,1 Variable emission CO2=9,10 NOX=0,030 HC=0,0003 CO=0,012 75% Payload: Costant emission CO2=2554 NOX=13,3 HC=0,36 CO=6,3 Variable emission CO2=9,35 NOX=0,031 HC=0,0003 CO=0,124 100% Payload: Constant emission CO2=3302 NOX=17,6 HC=0,375 CO=6,532 Variable emission CO2=9,48 NOX=0,032 HC=0,0003 CO=0,012
About Data	Data are calculated from the simulation method of the Aeronautical Research Institute of Sweden (FFA). For the calculation of emissions from the jet plane (Airbus A 300-B4), the flight simulation method of the Aeronautical Research Institute of Sweden (FFA) has been used. FFA has used a software tool ''PIANO'', developed for studies of aircraft design. The tool contains a

	database with aerodynamical data for different aircrafts and engines. The emission data is from ICAO emission database (ICAO,1995). The calculations in PIANO is calibrated after results from the EU-project AEROCERT (Näs P, 1998) in which samples from real life flights has been analysed. References: - ICAO Engine Exhaust Emissions Data Bank, Doc 9646 AN/943, (1995) - Dimitri Simos, PIANO, Project Interactive Analysis and Optimization, User's Guide, Lissys Limited, Woodhouse Eaves LE 12 8RL, United Kingdom 1997 - Patrik Näs, Aircraft Engine Emissions and Operational Procedures – Analysis of Flight Data Recorder for AEROCERT, FFA TN 1998-56, Bromma, 1998
Notes	The person stated as ''Practitioner'' is the contact person for the data for transportation by plane in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: Jet plane, A 300-B4, 600 km

Administrative	
Finished	Y
Date Completed	1999 - 12
Copyright	NTM
Availability	Public

Technical System	
Name	Jet plane, A 300-B4, 600 km
Functional Unit	1 tonkm, 75 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 km calculated for 600 km flight distance and an average utilisation level equivalent to 75 % of the aircrafts maximum payload capacity.
Process Type	Gate to gate
Site	Sweden
Sector	Air transport
Owner	Sweden
Technical system description	Operation of jet plane, type Airbus A 300-B4 with 2 engines Rolls Royce RB211-524, 600 km, Swedish domestic flight, with 8 minutes of taxiing and landing run (3 min. in and 5 min. out). This is a larger plane, with a capacity of approximately 270 passengers in a passenger version. The plane presented here, however, is strictly a freight version which seats no passengers. Utilisation level is set to 75% for the medium quantity, 100% for ''min'' and 50% for ''max''. Fuel: Jet-A1. Takeoff Weight (TOW): 170 tons. Speed (cruise): 897 km/h. Maximum payload 45 000 kg.

System Boundaries

Nature Boundary	Regulated missions to air from combustion of the fuel are included. The parameters that are presented are: - Regulated emissions for diesel engines:NOx, HC, Particles and CO - Fuel regulated: SO2 - Tax regulated CO2 Other environmental impacts, e.g., diffuse emissions to air, emissions to water and ground, noise, encroachment, from the operation of the aircraft are not included.
Time Boundary	The data represents aircrafts in use in 2000.
Geographical Boundary	Data is based on Swedish and European conditions.
Other Boundaries	The distance chosen is 600 km, which is a typical distance for domestic goods transport flights in Sweden. The medium quantity implies a utilisation level of 75% , ''min'' implies a utilisation level of 100% and ''max'' 50%. Parameters not considered: External conditions i.e. climate etc. Maintenance level of the aircraft. Excluded subsystems: Precombustion i.e. production and distribution of fuels Maintanence and aftertreatment of the aircraft Handling of production rests
Allocations	N/A
Systems Expansions	N/A

About Inventory

Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology

	Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.

About Inventory

Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage

	Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.

Practitioner	Pålsson, Anette - FFA, Bromma .
Reviewer	None, to be reviewed. -
Applicability	The emissions vary considerably between different types of aircraft and engine combinations. Thus, the emission data given in this context are only applicable to the specific type of aircraft and distances of this example. Provided that the plane types presented in this context are representative for their categories (size and age), the figures may be used for estimations of total emissions from a certain traffic volume. The total amount of emissions depends on a number of parameters of which the most important are starting weight and transportation distance. The longer the distance, the higher the emissions per flight, but lower per tonkm, since take-off and landing always have to take place in a flight. The distance chosen is 600 km, which is a typical distance for domestic flights for goods transport in Sweden. The aircraft presented is a version that carries only goods. It is a rather old version, but still rather commonly used for goods transport in Sweden and in Europe. It is a jet with 3 engines and in a passenger version it would carry 200 passengers. The taxiing and landing run time chosen is 8 minutes (3 min. in, 5 min. out). Taxiing and loading run time depends mainly on the airport. The medium quantity implies a utilisation level of 75% , ''min'' implies a utilisation level of 100% and ''max'' 50%. For calculations of emissions from flights of other distances than the ones given, the following relations can be used. They apply to flights of distances between 600 - 1200 km, with Boeing 727-200. Total emissions = Constant emission (kg) + Variable emission (kg/km) * distance (km) 50% payload: Constant emission CO2=4027 NOX=22,2 HC=3,39 CO=9,7 Variable emission CO2=14,93 NOX=0,043 HC=0,0081 CO=0,040 75% Payload: Costant emission CO2=4727 NOX=26,5 HC=3,41 CO=9,2 Variable emission CO2=15,44 NOX=0,046 HC=0,008 CO=0,0389 100% Payload:

	Constant emission CO_2=5829 NO_X=32,275 HC=3,638 CO=9,654 Variable emission CO_2=15,36 NO_X=0,047 HC=0,0075 CO=0,036
About Data	Data are calculated from the simulation method of the Aeronautical Research Institute of Sweden (FFA). For the calculation of emissions from the jet plane (Boeing 727-200), the flight simulation method of the Aeronautical Research Institute (FFA) has been used. FFA has used a software tool ''PIANO'', developed for studies of aircraft design. The tool contains a database with aerodynamical data for different aircrafts and engines. The emission data is from ICAO emission database (ICAO,1995). The calculations in PIANO is calibrated after results from the EU-project AEROCERT (Näs P, 1998) in which samples from real life flights has been analysed. References: - ICAO Engine Exhaust Emissions Data Bank, Doc 9646 AN/943, (1995) - Dimitri Simos, PIANO, Project Interactive Analysis and Optimization, User's Guide, Lissys Limited, Woodhouse Eaves LE 12 8RL, United Kingdom 1997 - Patrik Näs, Aircraft Engine Emissions and Operational Procedures – Analysis of Flight Data Recorder for AEROCERT, FFA TN 1998-56, Bromma, 1998
Notes	The person stated as ''Practitioner'' is the contact person for the data for transportation by plane in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: Jet plane, B737-300QC, 1200 km

Administrative	
Finished	Y
Date Completed	1999 - 12
Copyright	NTM
Availability	Public

Technical System	
Name	Jet plane, B737-300QC, 1200 km
Functional Unit	1 tonkm, 75 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 km calculated for 1200 km flight distance and an average utilisation level equivalent to 75 % of the aircrafts maximum payload capacity.
Process Type	Gate to gate
Site	Sweden
Sector	Air transport

Owner	Sweden
Technical system description	Operation of an airplane, type Boeing B737-300QC with 2 engines General Electric CFM56-3C-1, 600 km, Swedish domestic flight, with 8 minutes of taxiing and landing run (3 min. in and 5 min. out). In a passenger version, the plane can seat almost 150 passengers. The plane presented here, however, is strictly a freight version which seats no passengers. Utilisation level is set to 75% for the medium quantity, 100% for ''min'' and 50% for ''max''. Fuel: Jet-A1. Takeoff Weight (TOW): 60 tons. Speed (cruise): 820 km/h. Maximum payload 17 700 kg.

System Boundaries

Nature Boundary	Regulated missions to air from combustion of the fuel are included. The parameters that are presented are: - Regulated emissions for diesel engines:NOx, HC, Particles and CO - Fuel regulated: SO2 - Tax regulated CO2 Other environmental impacts, e.g., diffuse emissions to air, emissions to water and ground, noise, encroachment, from the operation of the aircraft are not included.
Time Boundary	The data represents aircrafts in use in 2000.
Geographical Boundary	Data is based on Swedish and European conditions.
Other Boundaries	The distance chosen is 1200 km, which is a typical distance for goods transport flights in Europe. The medium quantity implies a utilisation level of 75% , ''min'' implies a utilisation level of 100% and ''max'' 50%. Parameters not considered: External conditions i.e. climate etc. Maintenance level of the aircraft. Excluded subsystems: Precombustion i.e. production and distribution of fuels Maintanence and aftertreatment of the aircraft Handling of production rests
Allocations	N/A
Systems Expansions	N/A

About Inventory

Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business.

	The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	Pålsson, Anette - FFA, Bromma .
Reviewer	None, to be reviewed. -
Applicability	The emissions vary considerably between different types of aircraft and engine combinations. Thus, the emission data given in this context are only applicable to the specific type of aircraft and distances of this example. Provided that the plane types presented in this context are representative for their categories (size and age), the figures may be used for estimations of total emissions from a certain traffic volume. The total amount of emissions depends on a number of parameters of which the most important are starting weight and transportation distance. The longer the distance, the higher the emissions per flight, but lower per tonkm, since take-off and landing always have to take place in a flight. The distance chosen is 1200 km, which is a typical distance for European flights for goods transport in Sweden. The aircraft presented is a version that carries only goods. It is commonly used for goods transport in Sweden and in Europe. It is a large (Jumbo) jet with 4 engines and in a passenger version it would carry more than 400 passengers. The taxiing and landing run time chosen is 8 minutes (3 min. in, 5 min. out). Taxiing and loading run time depends mainly on the airport. The medium quantity implies a utilisation level of 75% , ''min'' implies a utilisation level of 100% and ''max'' 50%. For calculations of emissions from flights of other distances than the ones given, the following relations can be used. They apply to flights of distances between 600 - 1200 km, with Boeing 747-200. Total emissions = Constant emission (kg) + Variable emission (kg/km) * distance (km) 50% payload: Constant emission CO2=5905 NOX=162,4 HC=0,0002 CO=0,020 Variable emission CO2=32,93 NOX=0,272 HC=0,0002 CO=0,020 75% Payload: Costant emission CO2=920 NOX=65,2 HC=4,91 CO=31,2 Variable emission CO2=37,7 NOX=0,342

	HC=0,0002 CO=0,0205 100% Payload: Constant emission CO2=-2469 NOX=72,2 HC=4,8798 CO=29,338 Variable emission CO2=43,30 NOX=0,407 HC=0,0002 CO=0,023
About Data	Data are calculated from the simulation method of the Aeronautical Research Institute of Sweden (FFA). For the calculation of emissions from the jet plane (Boeing 747-200), the flight simulation method of the Aeronautical Research Institute (FFA) has been used. FFA has used a software tool ''PIANO'', developed for studies of aircraft design. The tool contains a database with aerodynamical data for different aircrafts and engines. The emission data is from ICAO emission database (ICAO,1995). The calculations in PIANO is calibrated after results from the EU-project AEROCERT (Näs P, 1998) in which samples from real life flights has been analysed. References: - ICAO Engine Exhaust Emissions Data Bank, Doc 9646 AN/943, (1995) - Dimitri Simos, PIANO, Project Interactive Analysis and Optimization, User's Guide, Lissys Limited, Woodhouse Eaves LE 12 8RL, United Kingdom 1997 - Patrik Näs, Aircraft Engine Emissions and Operational Procedures – Analysis of Flight Data Recorder for AEROCERT, FFA TN 1998-56, Bromma, 1998
Notes	The person stated as ''Practitioner'' is the contact person for the data for transportation by plane in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: Jet plane, B747-400, 600 km

Administrative	
Finished	Y
Date Completed	1999 - 12
Copyright	NTM
Availability	Public

Technical System	
Name	Jet plane, B747-400, 600 km
Functional Unit	1 tonkm, 75 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 km calculated for 600 km flight distance and an average utilisation level equivalent to 75 % of the aircrafts maximum payload capacity.

Process Type	Gate to gate
Site	Sweden
Sector	Air transport
Owner	Sweden
Technical system description	Operation of jet plane, type Boeing B747-400 with 4 engines General Electric CF6-80C2A3, 600 km, Swedish domestic flight, with 8 minutes of taxiing and landing run (3 min. in and 5 min. out). The plane is a jumbojet, which in a passenger version seats more than 400 passengers. The plane presented here, however, is strictly a freight version which seats no passengers. Utilisation level is set to 75% for the medium quantity, 100% for ''min'' and 50% for ''max''. Fuel: Jet-A1. Takeoff Weight (TOW): 394,6 tons. Speed (cruise): 910 km/h. Maximum payload 93 000 kg.

System Boundaries	
Nature Boundary	Regulated missions to air from combustion of the fuel are included. The parameters that are presented are: - Regulated emissions for diesel engines:NOx, HC, Particles and CO - Fuel regulated: SO2 - Tax regulated CO2 Other environmental impacts, e.g., diffuse emissions to air, emissions to water and ground, noise, encroachment, from the operation of the aircraft are not included.
Time Boundary	The data represents aircrafts in use in 2000.
Geographical Boundary	Data is based on Swedish and European conditions.
Other Boundaries	The distance chosen is 600 km, which is a typical distance for domestic goods transport flights in Sweden. The medium quantity implies a utilisation level of 75% , ''min'' implies a utilisation level of 100% and ''max'' 50%. Parameters not considered: External conditions i.e. climate etc. Maintenance level of the aircraft. Excluded subsystems: Precombustion i.e. production and distribution of fuels Maintanence and aftertreatment of the aircraft Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Applicability	To calculate the total environmental load, including the cement production, you can use the data in this Database at: Name: Production of cement Category:Cradle to gate Publication:LCA of Builing Frame Structures Environmental Impact over the Life Cycle of Wooden and Concrete frame; Björklund T., Tillman A-M.; Report 1997:2; Technical Environmental Planning; Chalmers University of Technology, Göteborg, Sweden The function of the technical system is not sufficently described. Contact Färdig betong AB Box 5162 402 26 Göteborg Sweden

	Phone +46 -31 7081500 to get the necessary details.
About Data	Aggregates It has to be noted that aggregates are considered to a nearly unlimited resource but in some parts of Sweden natural aggregates are very scarce. Substitutes are made from crushed blocks of stone to some greater energy expense compared to that of natural aggregates. In the study, all aggregates are regarded as natural aggregates. No calculation of energy use at the aggregate pit has been done. Additives Quantities of the admixtures are unknown, therefore, they are not taken into account. Water Water is taken from the community water system. It is in the study not regarded as a resource and is consequently not invented up-streams the flow. The density of K30 is calculated to 2 366 ton/m3. Waste Waste concrete from return deliveries and concrete from cleaning of the concrete mixer is reported to be 1.5 percent of the annual production. Transports not considered in this set of data: The cement is transported by truck about 160 km from Cementa's plant in Skövde to storages in Vallhamn and Varberg. The aggregates are delivered from Östad and Sjögärde, about 40 km by truck. The average distance to the customer is estimated to 30 km and the K30 is transported by truck.
Notes	-- --- Changes made to the data set after publishing in SPINE@CPM--- >>> 18 September 2001: <<< Changes made by Ann-Christin Pålsson, CPM based on the original report Comments: The data for oil and electricity use have been corrected to be in accordance with the original report.

About Inventory

Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. --- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden ---
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998

	OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998

Reviewer	
Applicability	Emission factors for the diesel combustion and the electricity used in the system are not accounted for. Also the emission caused by the degradation of organic matter is not accounted for in the data set. The data are valid for Swedish conditions, but can be used as an approximation to other countries. One should though be aware of the fact that the situation in other countries may be very different and depending on this one gets an unreliable result. The data are based on old sources (Swedish waste disposal 1990, RVF) and should therefore not be regarded as information describing the current situation.

SPINE LCI dataset: Landfilling of solid municipal waste

Administrative	
Finished	Y
Date Completed	2002-08-14
Copyright	McDougall F. et al, Integrated Solid Waste Management
Availability	Public

Technical System	
Name	Landfilling of solid municipal waste
Functional Unit	1 tonne of waste landfilled
Functional Unit Explanation	1 tonne of waste landfilled is waste from waste collection and sorting stations, biological treatment and thermal treatment plants.
Process Type	Gate to gate
Site	Europe
Sector	
Owner	Europe
Technical system description	Landfill is a waste treatment process with its own inputs and outputs, rather than simply a sink for the final disposal of solid waste. The environmental burdens of landfilling waste will depend both on the landfill design and method of operation, and the nature of the waste deposited. Included in the landfill system boundary are landfill, landfill gas collection, landfill gas combustion, hazardous landfill and leachate treatment. There are four main waste streams from municipal solid waste management systems that are landfilled. Inputs are: Restwaste (can be total Municipal solid waste), Sorting residue, Biological treatment residue and Thermal treatment residues (ash, filter dust and other residues from gas cleaning). Input streams can be divided into two groups; non-hazardous and hazardous. The inputs to the landfill system occur over a limited time period, i.e. the working life of the site. The outputs from the system occur over a much longer time span, which may involve at least tens and maybe hundreds of years. Outputs are: -- Landfill gas from biodegradable fraction in Municipal solid waste and biologically treated material (it is assumed for the purpose of this model that no landfilled gas is produced from ash) -- Leachate which result in solid waste residue from leachate treatment -- Inert solid waste from landfilled waste Outputs will depend on many factors e.g. the nature of the waste, method and level of compaction and the engineering of the landfill (how well the landfill is sealed). Landfill gas: Landfill gas is produced by an anaerobic decomposition of biodegradable organic material. The composition of the gas released will vary through the different phases of the active life of a landfill site. The composition of landfill gas is similar to that of biogas, and the heat content is similar. A typical composition of landfill gas also used in this documentation is given below (% by volume)(WMI, 1994): Methane, 52.8% Carbon dioxide, 44.1% Oxygen, 0.5% Nitrogen, 2% If no collection system exists for gas control or energy recovery, all of the landfill gas eventually leak out of the site and enter the atmosphere. Where gas collection occurs like in this model, around 40% will typically be recovered, whilst the remaining 60% still enters the atmosphere. (McDougall, 2001) Leachate: Any leachate treatment residues will be added to the total amount of final solid waste (Residual waste). The amount of leachate produced depends on many factors, for example the amount of rainfall on a landfill site. Leachate consists of organic C, N, F, P, S, Cl and heavy metals such as Cd, Cu, Hg, Pb and Zn. Composition of leachate varies with the stage

	of decomposition of the waste (e.g. pH, concentration of BOD, COD etc) Energy: The landfill process will consume energy both in the form of vehicle fuel and electricity. For all waste types landfilled, fuel and electricity will be consumed in the operation of the site itself. Data suggest that the fuel consumption for the landfilling process is around 0.6 litres of diesel per cubic metre of void space filled.(Biffa Waste Service, 1994) Energy recovery involves burning of landfill gas in a gas engine to generate electricity. Electrical recovery of 1.5 kWh/Nm3 of landfill gas collected gives 525 kWh per tonne waste landfilled, with an assumed conversion efficiency of 30% (ETSU, 1995). References: Waste Management International, Landfill Gas Data, Waste Management International, London, 1994 Integrated Waste Management - a Life Cycle Inventory, F. System Boundaries

Nature Boundary	A landfill site consumes land and the final solid waste fills up a volume, how much is not presented in this documetation due to lack of data. Emissions to air from landfill gas, are only represented of Methane, Carbon dioxide, Oxygen and Nitrogen (they are the main components in landfill gas) Methane has been reported to be responsible for about 20% (Lashof and Ahuja, 1990) of recent increase in global warming and landfills are thought to be the major source of methane. Emissions from generation of electricity from landfill gas within the system are not included due to lack of data. Emissions to water from different materials in the waste and emissions from leachate are not included in the system due to lack of data. Reference: Lashof and Ahuja,Relative contribution to greenhouse gas emissions to global warming, Nature, 344, April, 1990
Time Boundary	The inputs to the landfill system occur over a limited time period, i.e. the working life of the site, about 30 years.(McDougall, IWM, 2001) Data was collected during 1992-2001
Geographical Boundary	This activity represents a landfill site in a European country.
Other Boundaries	There are no data presented on electricity used in the landfill activity. Combustion of landfill gas is included in the system but data on emissions during power generation could not be found. All leachate produced is collected as residual waste. Leachate collection and treatment will consume energy, but that is not included due to lack of suitable data.

Method: The composition of landfill gas usually is 44.1% CO2, 52.8% CH4, 0.5 % O2 and 2% N2 (% by volume)(WMI, 1994) 60% of landfill gas enters the atmosphere since 40% of gas is used for energy recovering.60% of landfill gas (350Nm3/tonne waste) is 210 Nm3/tonne. Density of N2 (0* Celcius, 100 kPa)=1.95 kg/m3 Literature: Waste Management International, Landfill Gas Data, Waste Management International, London, 1994	Output	Emission	N2	5.17			kg	Air	
Method: The composition of landfill gas usually is 44.1% CO2, 52.8% CH4, 0.5 % O2 and 2% N2 (% by volume)(WMI, 1994) 60% of landfill gas enters the atmosphere since 40% of gas is used for energy recovering.60% of landfill gas (350Nm3/tonne waste) is 210 Nm3/tonne. Density of O2 (0* Celcius, 100 kPa)=1.41 kg/m3 Literature: Waste Management International, Landfill Gas Data, Waste Management International, London, 1994	Output	Emission	O2	1.48			kg	Air	
Method: Landfill gas (52.8% CH4, 44.1% CO2, 0.5 O2, 2% N2) has an energy content of about 18 MJ/Nm3, with a calorific value of 37.75 MJ/Nm3 for methane. (McDougall, 2001) Landfill gas produced is 350 Nm3/tonne input waste (250 Nm3/tonne from biodegradable fractions in Municipal solid waste + 100 Nm3/tonne from biol.treatment products). It is assumed by McDougall, 2001 that 140 Nm3 is collected. Assume 60% energy recovery from gas and 30% efficiency of electricity generation gives 1.5 kWh/Nm3 of landfilled gas collected. 1.5*140= 210 kWh (McDougall, 2001)(Perry and Green,1997) Literature: Perry and Green, The Chemical Engineer'sHandbook, McGraw Hill, 1997. Integrated Waste Management - a Life Cycle Inventory, F. McDougall et al, Procter & Gamble Technical Centres Limited, Blackwell Science, 2001	Output	Product	Electricity	210			kWh	Technosphere	

Method: An estimation that around 13 % of the rainfall on a landfill site emerges as leachate, has been made. For sites in Germany with an average annual rainfall of 750 mm, this would produce around 100 litres of leachate per square metre of landfill site, per year. With a 20-metre dept of waste and density of 1 tonne/m3 gives a leachate production of 5 litres per tonne landfilled waste per year. If the active period for leachate production is around 30 years, the total amount would be 150 litres per tonne waste. (McDougall, IWM, 2001) 0.015 tonne solid waste from leachate treatment/m3 of leachate treated and 150 litre (0.15m3)/tonne waste input, result in a residual waste of 2.25 kg which were added to the inert solid waste landfilled. (McDougall, IWM, 2001) Literature: Integrated Waste Management - a Life Cycle Inventory, F. McDougall et al, Procter & Gamble Technical Centres Limited, Blackwell Science, 2001 Notes: Density of Residual waste was estimated to be 1.032 ton/m3 (McDougall, 2001) giving a volume of 971.2 m3 of residual waste.	Output	Product	Residual waste	1002.25			tonne	Ground	

About Inventory

Publication	McDougall F. et al, Integrated Solid Waste Management - A Life Cycle Inventory, Procter & Gamble Technical Centres Limited, Blackwell Science, 2001 Data documented by: Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Documentation reviewed by: Ann-Christin Pålsson, Industrial Environmental Informatics, Chalmers University of Technology Published in SPINE@CPM: 14 August 2002
Intended User	The original study this d
General Purpose	Data about waste management systems are insufficient and more data are required by the industry.
Detailed Purpose	This documentation is based on a study about Integrated Solid Waste Management performed by Forbes McDougall et al at Procter& Gamble Technical Centres, 2001. The aims of that study was to introduce a LCI model for Integrated Waste Mangement and to provide data that support the concept of Integrated Waste Management as a sustainable method of managing solid waste. The purpose of the documentation of this system has been to make data for waste management available in this format for the industry.

Reviewer	
Applicability	The environmental burdens of landfilling waste will depend on the landfill design and method of operation, and the nature of the waste deposited. There are not much data available for individual material fractions in the inputs and outputs and the ones available generally refer to the landfilling of mixed waste streams, such as Municipal solid waste. It is difficult to provide typical figures for the generation of leachate and landfill gas from landfilled wastes. For leachate both the amount and composition of leachate will depend on many factors, including the nature of the waste, method and level of compaction, the engineering design of the landfill (e.g. how well the landfill is sealed) and the annual rainfall of the region. German scientists have estimated that around 13 % of the rainfall on a landfill site emerges as leachate. For sites in Germany with an average annual rainfall of 750mm, this would produce around 100 litres of leachate per square metre of landfill site, per year. With a 20-metre dept of waste, density 1 tonne/m3 gives a leachate production of 5 litres per tonne landfilled waste per year. If the active period for leachate production is around 30 years, the total amount would be 150 litres per tonne waste. Composition of leachate varies with the stage of decomposition of the waste (e.g. pH, concentration of BOD, COD etc) Outputs will depend on many factors e.g. the nature of the waste, method and level of compaction and the engineering of the landfill (how well the landfill is sealed). The landfill process will consume energy both in the form of vehicle fuel and electricity. For household waste that is landfilled directly, where the distance from the collection area to

	the landfill site is large, a transfer station may be used to bulk up the waste for more efficient transport by larger truck or rail. There are no data available on the energy consumption of transfer stations, therefore they are not includedin this activity, but generic fuel consumption data for road transport can be used. For all waste types landfilled, fuel and electricity will also be consumed in the operation of the site itself. Data suggest that the fuel consumption for the landfilling process is around 0.6 litres of diesel per cubic metre of void space filled.(Mc Dougall, Integrated Waste Management, 2001) Landfill gas not only consists of Methane, Carbon dioxide, Oxygen and Nitrogen but also of smaller amounts of Ethane, Hydrogen sulfide, propane, Toluene, xyelne etc. Methane has been reported to be responsible for about 20% of recent increase in global warming and landfills are thought to be the major source of methane.(Lashof and Ahuja, Relative contribution to greenhouse gas emissions to global warming, Nature, 344, April, 1990)
About Data	Data is based on a study performed by Procter & Gambler about Integrated Waste Management (McDougall F. et al, Procter & Gamble Technical Centres Limited, Blackwell Science, 2001). Data are generally averages, giving an approximate measure of the environment burdens associated with the system. The descriptions of the activity is how it was understood by the person who made the documentation.
Notes	For further information about solid waste managment see: Flemström K., Brief overview of solid waste management, IMI-internal report. The report may be downloaded from: http://www.imi.chalmers.se

Availability	Public

Technical System	
Name	Light truck, distribution, Euro 0

Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. (NOTE! DIFFERS FROM OTHER DISTRIBUTION VEHICLES WHICH ARE CALCULATED FOR A UTILISATION FACTOR OF 50%. THIS WILL BE CORRECTET IN THE NEXT UPDATE OF NTM) An utilisation level of 50 % is considered to be representative for Swedish domestic distribution traffic if *empty trips are not included.*
Process Type	Gate to gate
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of diesel driven light truck for distribution, approximately 9 m long with a curb weight of 14 tons and a maximum load of 8.5 tons. The vehicle is mainly used for local distribution, mainly in city traffic. Fuel: diesel, MK 1 (sulphurous content: 2 ppm). Fuel consumption: high 3 l/10 km, medium 2.75 l/10 km, low 2.5 l/10 km. Engine type: Euro 0 (manufactured before 1992). Utilisation level: 70% by weight. (NOTE! DIFFERS FROM OTHER DISTRIBUTION VEHICLES WHICH ARE CALCULATED FOR A UTILISATION FACTOR OF 50%. THIS WILL BE CORRECTET IN THE NEXT UPDATE OF NTMS' HOMEPAGE)

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	Data are valid for trucks produced 1987 - 1992
Geographical Boundary	Data is based on Swedish conditions.
Other Boundaries	The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic. Empty trips are not included. *Parameters not considered* -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, unspecified
Represents	NTM
Method	Data have been put together for NTM by a group of manufacturers and hauliers, i.e. Volvo, Scania, BTL, ASG, Swedish Hauliers Assosiation. Data are presented in relation to the transport work, in g/tonkm. The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic and 70 % for long distance transport with heavy trucks. The utilisation level is based on the load carrying weight, i.e. the weight on which the customer price is based. This means that bulky cargo is multiplied with a factor in order to compensate for taking up volume. The average break-point density is 275 kg/m3. Energy use and emissions per tonkm with a truck should be based on the load carrying

	weight. The *quantity value for the energy use* refer to average fuel consumption, the *maximum and minimum value* refer to changes in the fuel consumption due to degeneration, driving behaviour etc.. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, The emission data have been produced through simulations conducted by Volvo Trucks and Scania in 1997. The simulations were based on certification values for engines and fuel consumption under actual operation for Swedish conditions. For medium and light lorries, the emission values have been obtained from certification values for new engines that are operated in accordance with established operating cycles, e.g. ECR-49 (IVL and Mercedes). Emissions data related to fuel consumption Emission factors (g/liter) Euro 0 Euro 1 Euro 2 Law from: 1980 1990 1993 1996 NOx 52+/- 5 44 27 23 HC 6+/- 2 2.1 1.8 1.3 PM 3+/- 2 1 0.5 0.35 CO 8+/- 3 3.7 3.4 2.5 This shows emissions factors in g/l for heavy lorries. With fuel consumption as a basis, it is possible to calculate the emissions. The data on emissions are based on measurements in accordance with applicable standards for certification. liters/100 km Empty Full load Distribution lorry (Payload 8.5 ton) 20-25 25-30 Med.-size lorry (Payload 14 ton) 25-30 30-40 Heavy lorry w trailer (Payl. 26 ton) 22-27 32-38 Heavy lorry w 2 trail. About Inventory

Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the

	technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	Björkman, Mikael - BTL 412 97 Göteborg .
Reviewer	None, to be reviewed. -
Applicability	The data should not be used for any detailed study of transport systems. More detailed information is needed in order to carry out such studies, e.g. regarding the vehicle -type -age and performance, fuel type, the nature of the goods, the utilisation level etc. For a specific transport, the company carrying out the transport should be contacted in order to get information on how the goods are handled and how the transport is carried out. Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred. The standard values presented in this activity should not be used if specific information on the fuel consumption for the transport is availiable. In this case, the fuel consumption should instead be used as a basis to calculate the emissions from the transport. See General QMetaData for emission factors that can be used to calculate emissions per litre fuel used. The age categories of the vehicles compiled in the work are: Older than 1990, Euro 0: Introduced 1987, law from 1990 Euro 1: Introduced 1991, law from 1993 Euro 2: Introduced 1993, law from 1996 However, in order to improve the accuracy of the calculations, the user ought to know the Euro-class (emission standards) of the vehicle, rather than to base the calculations on the age of the vehicle. ***Handling of goods*** The data presented by NTM is representative for a terminal based transport system. The vehicles can be used in different ways, primarily altering the degree of utilisation. Several other types of road based cargo transport systems is not well described by the data (e.g. oil and excavated materials) Terminal based road transports generally consists of 1-3 parts: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles while the inter-terminal traffic is operated by larger units, typically with a higher degree of utilisation. *--Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. *--General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited *--Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used in terminal based transport systems in Sweden:*** *--Parcel truck/van, max 3,5 tonnes* is mainly used for transportation of parcels. *--Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. *--Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. *--Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. *--Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. *--Truck with semi-trailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for an utilisation level of 70 % for long distance transport and 50 % for local distribution and regional transport, which is considered representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip, due to specialised vehicles). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than smaller firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden):

	-excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1, except for petrol driven delivery vans who are assumed to use standard unleaded petrol. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (> 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the data. NGM propose that data from Blinge et. al (Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997) should be used. This study is based on best available technology and Swedish conditions which is likely to yield a low figure. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. This will alter both the SOx emission and the regulated engine emissions. Generally the fleets in western Europe is composed of newer vehicles than in Sweden. The utilisation of the vehicles may also vary in different countries.
About Data	The emission data of medium-sized and light trucks have been collected from certification values of new engines, driven according to fix driving cycles, e.g. ECR-49 (IVL and Mercedes).
Notes	The person stated as ''Practitioner'' is the contact person for the data for truck transportation in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: Light truck, distribution, Euro 1

Administrative	
Finished	Y
Date Completed	1998 - 08
Copyright	NTM
Availability	Public

Technical System	
Name	Light truck, distribution, Euro 1
Functional Unit	1 tonkm, 50 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 50 %. An utilisation level of 50 % is considered to be representative for Swedish domestic distribution traffic if *empty trips are not included.*
Process Type	Gate to gate
Site	Sweden

Sector	Land transport
Owner	Sweden
Technical system description	Operation of light truck for distribution, approximately 9 m long with a curb weight of 14 tons and a maximum load of 8.5 tons. Fuel: diesel, MK 1 (sulphurous content: 2 ppm). Fuel consumption: high 3 l/10 km, medium 2.75 l/10 km, low 2.5 l/10 km. Engine type: Euro 1 (1993-1995). Utilisation level: 50% by weight.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	Data are valid for trucks produced 1991 - 1995
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic. Empty trips are not included. *Parameters not considered* -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data	
General Activity QMetaData	
Date Conceived	1998 - 08
Data Type	Derived, unspecified
Represents	NTM

Method	Data have been put together for NTM by a group of manufacturers and hauliers, i.e. Volvo, Scania, BTL, ASG, Swedish Hauliers Assosiation. Data are presented in relation to the transport work, in g/tonkm. The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic and 70 % for long distance transport with heavy trucks. The utilisation level is based on the load carrying weight, i.e. the weight on which the customer price is based. This means that bulky cargo is multiplied with a factor in order to compensate for taking up volume. The average break-point density is 275 kg/m3. Energy use and emissions per tonkm with a truck should be based on the load carrying weight. The *quantity value for the energy use* refer to average fuel consumption, the *maximum and minimum value* refer to changes in the fuel consumption due to degeneration, driving behavour etc.. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, The emission data have been produced through simulations conducted by Volvo Trucks and Scania in 1997. The simulations were based on certification values for engines and fuel consumption under actual operation for Swedish conditions. For medium and light lorries, the emission values have been obtained from certification values for new engines that are operated in accordance with established operating cycles, e.g. ECR-49 (IVL and Mercedes). Emissions data related to fuel consumption Emission factors (g/liter) Euro 0 Euro 1 Euro 2 Law from: 1980 1990 1993 1996 NOx 52+/- 5 44 27 23 HC 6+/- 2 2.1 1.8 1.3 PM 3+/- 2 1 0.5 0.35 CO 8+/- 3 3.7 3.4 2.5 This shows emissions factors in g/l for heavy lorries. With fuel consumption as a basis, it is possible to calculate the emissions. The data on emissions are based on measurements in accordance with applicable standards for certification. liters/100 km Empty Full load Distribution lorry (Payload 8.5 ton) 20-25 25-30 Med.-size lorry (Payload 14 ton) 25-30 30-40 Heavy lorry w trailer (Payl. 26 ton) 22-27 32-38 Heavy lorry w 2 trail. About Inventory

Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.

Practitioner	- Swedish haulages and transport companies .
Reviewer	None, to be reviewed. -
Applicability	The data should not be used for any detailed study of transport systems. More detailed information is needed in order to carry out such studies, e.g. regarding the vehicle -type -age and performance, fuel type, the nature of the goods, the utilisation level etc. For a specific transport, the company carrying out the transport should be contacted in order to get information on how the goods are handled and how the transport is carried out. Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred. The standard values presented in this activity should not be used if specific information on the fuel consumption for the transport is availiable. In this case, the fuel consumption should instead be used as a basis to calculate the emissions from the transport. See General QMetaData for emission factors that can be used to calculate emissions per litre fuel used. The age categories of the vehicles compiled in the work are: Older than 1990, Euro 0: Introduced 1987, law from 1990 Euro 1: Introduced 1991, law from 1993 Euro 2: Introduced 1993, law from 1996 However, in order to improve the accuracy of the calculations, the user ought to know the Euro-class (emission standards) of the vehicle, rather than to base the calculations on the age of the vehicle. ***Handling of goods*** The data presented by NTM is representative for a terminal based transport system. The vehicles can be used in different ways, primarily altering the degree of utilisation. Several other types of road based cargo transport systems is not well described by the data (e.g. oil and excavated materials) Terminal based road transports generally consists of 1-3 parts: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles while the inter-terminal traffic is operated by larger units, typically with a higher degree of utilisation. *--Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. *--General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited *--Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used in terminal based transport systems in Sweden:*** *--Parcel truck/van, max 3,5 tonnes* is mainly used for transportation of parcels. *--Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. *--Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. *--Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. *--Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. *--Truck with semi-trailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for an utilisation level of 70 % for long distance transport and 50 % for local distribution and regional transport, which is considered representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip, due to specialised vehicles). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than smaller firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %.

	Bulky goods The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1, except for petrol driven delivery vans who are assumed to use standard unleaded petrol. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (> 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the data. NGM propose that data from Blinge et. al (Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997) should be used. This study is based on best available technology and Swedish conditions which is likely to yield a low figure. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. This will alter both the SOx emission and the regulated engine emissions. Generally the fleets in western Europe is composed of newer vehicles than in Sweden. The utilisation of the vehicles may also vary in different countries.
About Data	The emission data of medium-sized and light trucks have been collected from certification values of new engines, driven according to fix driving cycles, e.g. ECR-49 (IVL and Mercedes).
Notes	The person stated as ''Practitioner'' is the contact person for the data for truck transportation in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: Light truck, distribution, made before 1990

Administrative	
Finished	Y
Date Completed	1998 - 08
Copyright	NTM
Availability	Public

Technical System	
Name	Light truck, distribution, made before 1990
Functional Unit	1 tonkm, 50 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 50 %. An utilisation level of 50 % is considered to be representative for Swedish domestic distribution traffic if *empty trips are not included.*
Process Type	Gate to gate
Site	Sweden
Sector	Land transport
Owner	Sweden

Technical system description	Operation of light truck for distribution, approximately 9 m long with a curb weight of 14 tons and a maximum load of 8.5 tons. Fuel: diesel, MK 1 (sulphurous content: 2 ppm). Fuel consumption: high 3 l/10 km, medium 2.75 l/10 km, low 2.5 l/10 km. Engine type: made before 1990. Utilisation level: 50% by weight.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	Data are valid for trucks produced before 1990
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic. Empty trips are not included. *Parameters not considered* -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1998 - 08
Data Type	Derived, unspecified
Represents	NTM
Method	Data have been put together for NTM by a group of manufacturers and hauliers, i.e. Volvo, Scania, BTL, ASG, Swedish Hauliers Assosiation. Data are presented in relation to the transport work, in g/tonkm. The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic and 70 % for long distance transport with heavy trucks. The utilisation level is based on the load carrying weight, i.e. the weight on which the customer price is based. This means that bulky cargo is multiplied with a factor in order to compensate for taking up volume. The average break-point density is 275 kg/m3. Energy use and emissions per tonkm with a truck should be based on the load carrying weight. The *quantity value for the energy use* refer to average fuel consumption, the *maximum and minimum value* refer to changes in the fuel consumption due to degeneration, driving behavour etc.. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, The emission data have been produced through simulations conducted by Volvo Trucks and Scania in 1997. The simulations were based on certification values for engines and fuel consumption under actual operation for Swedish conditions. For medium and light lorries, the emission values have been obtained from certification values for new engines that are operated in accordance with established operating cycles, e.g. ECR-49 (IVL and Mercedes). Emissions data related to fuel consumption Emission factors (g/liter) Euro 0 Euro 1 Euro 2 Law from: 1980 1990 1993 1996 NOx 52+/- 5 44 27 23 HC 6+/- 2 2.1 1.8 1.3 PM 3+/- 2 1 0.5 0.35 CO 8+/- 3 3.7 3.4 2.5 This shows emissions factors in g/l for heavy lorries. With fuel consumption as a basis, it is possible to calculate the emissions. The data on emissions are based on measurements in accordance with applicable standards for certification. liters/100 km Empty Full load Distribution lorry (Payload 8.5 ton) 20-25 25-30 Med.-size lorry (Payload 14 ton) 25-30 30-40 Heavy lorry w trailer (Payl. 26 ton) 22-27 32-38 Heavy lorry w 2 trail. About Inventory

Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	- Swedish haulages and transport companies .
Reviewer	None, to be reviewed. -
Applicability	The data should not be used for any detailed study of transport systems. More detailed information is needed in order to carry out such studies, e.g. regarding the vehicle -type -age and performance, fuel type, the nature of the goods, the utilisation level etc. For a specific transport, the company carrying out the transport should be contacted in order to get information on how the goods are handled and how the transport is carried out. Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in

a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred.

The standard values presented in this activity should not be used if specific information on the fuel consumption for the transport is availiable. In this case, the fuel consumption should instead be used as a basis to calculate the emissions from the transport. See General QMetaData for emission factors that can be used to calculate emissions per litre fuel used.

The age categories of the vehicles compiled in the work are:
Older than 1990,
Euro 0: Introduced 1987, law from 1990
Euro 1: Introduced 1991, law from 1993
Euro 2: Introduced 1993, law from 1996
However, in order to improve the accuracy of the calculations, the user ought to know the Euro-class (emission standards) of the vehicle, rather than to base the calculations on the age of the vehicle.

Handling of goods
The data presented by NTM is representative for a terminal based transport system. The vehicles can be used in different ways, primarily altering the degree of utilisation. Several other types of road based cargo transport systems is not well described by the data (e.g. oil and excavated materials)
Terminal based road transports generally consists of 1-3 parts:
1. Collection of the goods to terminal
2. Long-distance transport between terminals
3. Distribution of the goods from terminal
The collection and distribution routes are generally performed by smaller vehicles while the inter-terminal traffic is operated by larger units, typically with a higher degree of utilisation.

--Wholesale goods (>1000 kg) are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport.
--General goods (100-1000 kg) are generally handled via terminal. The goods may be both weight and volume limited
--Parcel goods (<100 kg) are normally handled in small vehicles

The following vehicles and equipages are used in terminal based transport systems in Sweden:
--Parcel truck/van, max 3,5 tonnes is mainly used for transportation of parcels.
--Light truck, max 8 tonnes is used for local distribution, mainly in city traffic.
--Truck, max 18 tonnes is used for district distribution and local distribution in city traffic.
--Truck, max 24 tonnes is mainly used for transportation of general (styckegods) and wholesale (partigods) goods.
--Heavy truck with trailer, max 60 tonnes is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland.
--Truck with semi-trailer, max 42 tonnes is used for international long-distance traffic.

Utilisation level
The data is only applicable for an utilisation level of 70 % for long distance transport and 50 % for local distribution and regional transport, which is considered representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip, due to specialised vehicles). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than smaller firms of haulage. The utilisation of company internal vehicles is generally low.

The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden):
-excavated materials and round timber - 50%
-manufactured products (wholesale goods) - slightly more than 20%
-provisions and animal forage - approx. 15%
-mixed cargo (general goods) approx - 10 %.

Bulky goods
The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.

Fuel
The fuel used is diesel environmental class 1, except for petrol driven delivery vans who are assumed to use standard unleaded petrol. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (> 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions.

Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the

	data. NGM propose that data from Blinge et. al (Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997) should be used. This study is based on best available technology and Swedish conditions which is likely to yield a low figure. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. This will alter both the SOx emission and the regulated engine emissions. Generally the fleets in western Europe is composed of newer vehicles than in Sweden. The utilisation of the vehicles may also vary in different countries.
About Data	The emission data of medium-sized and light trucks have been collected from certification values of new engines, driven according to fix driving cycles, e.g. ECR-49 (IVL and Mercedes).
Notes	The person stated as ''Practitioner'' is the contact person for the data for truck transportation in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: Light truck, max 3,5 tonnes, diesel driven

Date concieved: 1997-01-01 Data type: Unspecified, expert outspoke Method: The emission per tonkm was calculated from the fuel consumption using the sulphur content in the diesel **The following data was used in the calculations:** *Data for the fuel, diesel environmental class 1:* Thermal value: 43,43 MJ/kg Density: 0,81 kg/l Sulphur content: 10 ppm *Assumptions given by the Swedish Road Haulage Association:* -Average fuel consumption 0,18 l/km. -Utilisation level: 70 %, of the available loading capacity with regard to weight.	Output	Emission	SO_2	0.003			g	Air	

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Michael Björkman, BTL (Bilspedition Transportation and Logistics), contact person for road transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport

	companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Larson, Lars-Gunnar - FFA (Flygtekniska försöksanstalten), Box 11021 S-161 11 Bromma Sweden.
Reviewer	
Applicability	!The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles --*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. --*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited --*Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used for transportation in Sweden:*** --*Truck max 3,5 tonnes* is mainly used for transportation of parcels. --*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. --*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. --*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. --*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. --*Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute,

	the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.
About Data	The data for emissions is based on emission factors. The origin of the emission factors is not specified. This means that several parameters that influence the energy use and emissions in regular traffic are probably not considered, e.g. climate, topography, driving technique, maintenance etc. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially.
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Light truck, max 3,5 tonnes, gasoline driven

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Light truck, max 3,5 tonnes, gasoline driven
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is representative for Swedish domestic traffic if *empty trips are not included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden

Technical system description	Operation of a gasoline driven light truck. The vehicle is mainly used for transportation of parcels. Maximum gross weight: 3,5 tonnes. Kerb weight: 2,1 tonnes. Available loading capacity with regard to weight: 1,4 tonnes. Length: 5,5 metres.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for gasoline engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents vehicles in use in 1997
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission factors, together with assumptions on the fuel consumption, type of fuel used and utilisation level. See specific QMetaData for each flow. Method description for NOx, HC, particles and CO can be found under NOx The quantity value for the energy use refer to average fuel consumption, the maximum and minimum value refer to changes in the efficiency of the engine due to degeneration. The emissions of CO2 and SO2 is based on the fuel consumption.
Literature Reference	Integrated Waste Management - a Life Cycle Inventory, F. McDougall et al, Procter & Gamble Technical Centres Limited, Blackwell Science, 2001 Waste Management International, Landfill Gas Data, Waste Management International, London, 1994 Perry and Green, The Chemical Engineer'sHandbook, McGraw Hill, 1997.
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Björkman, Michael - BTL (Bilspedition Transportation and Logistics), 412 97 Göteborg .
Reviewer	
Applicability	The ambition with the data was to get a picture of future energy use and emissions. The data represents best available technology, not yet in use.
About Data	The data is based on tests on the engine performed in a laboratory according to a new test cycle (proposed for standardisation). This means that several parameters that influence the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially.
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Light truck, max 8 tonnes, manufactured after 1996 [Euro 2]

Administrative

Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System

Name	Light truck, max 8 tonnes, manufactured after 1996 [Euro 2]
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is representative for Swedish domestic traffic if *empty trips are not included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of a diesel driven light truck with engine manufactured after 1996 (Euro 2 environmental standard). The vehicle is mainly used for local distribution, mainly in city traffic. Maximum gross weight: 8 tonnes. Kerb weight: 5 tonnes. Available loading capacity with regard to weight: 3 tonnes. Length: 7 metres.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents trucks with engine manufactured after 1996
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission factors obtained by the ECE R49 test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level (see specific QMetaData for a description on methods used for each flow). The *quantity value for the energy use* refer to average fuel consumption, *the maximum and minimum value* refer to changes in the efficiency of the engine due to degeneration. The emissions of CO_2 and SO_2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, the quantity value* refer to an average engine guaranteed by Volvo Truck Corporation, the *maximum value* refer to an engine run 500 000 km. No minimum value was given.
Literature Reference	Integrated Waste Management - a Life Cycle Inventory, F. McDougall et al, Procter & Gamble Technical Centres Limited, Blackwell Science, 2001 Waste Management International, Landfill Gas Data, Waste Management International, London, 1994 Perry and Green, The Chemical Engineer'sHandbook, McGraw Hill, 1997.
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

	Input	Cargo	Cargo	1			tonne	Technosphere	
Date concieved: 1997-01-01 Data type: Unspecified, expert outspoke Method: The diesel consumption per tonkm was calculated using assumptions on average fuel consumption (l/km) and utilisation level. The fuel is assumed to be diesel, environmental class 1. The minimum and maximum value is based on assumptions on changes in the efficiency of the engine due to degeneration. ***The following data was used in the calculations:*** *Assumptions given by the Swedish Road Haulage Association:* -Average fuel consumption: 0,27 l/km. -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1, given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm *Change of efficiency of the engine (based on assumptions):* -minimum value: 0,99 in relation to the average engine -maximum value:1,01 in relation to the average engine	Input	Refined resource	Diesel environmental class 1	4.52	4.46	4.59	MJ	Technosphere	
	Output	Cargo	Cargo	1			tonne	Technosphere	
Method: See QMetaData for NOx.	Output	Emission	CO	0.36		0.44	g	Air	
Date concieved: 1997-01-01 Data type: Derived, unspecified Method: The emission per tonkm was calculated from the fuel consumption using the carbon content in the diesel. ***The following data was used in the calculations:*** *Assumptions given by the Swedish Road Haulage Association:* -Average fuel consumption 0,27 l/km. -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1 given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm -CO2 emission: 73 g/MJ fuel See QMetaData for the Diesel flow for further	Output	Emission	CO_2	330	325	335	g	Air	

information									
Method: See QMetaData for NOx.	Output	Emission	HC	0.21		0.22	g	Air	
Date concieved: 1997-01-01 Data type: Derived, unspecified Method: The following formula was used to calculate the emissions per tonkm: (Average fuel consumption [l/km]*thermal value[kWh (fuel)/l]*efficiency [kWh(engine)/kWh(fuel)]*emission factor [g/kWh(engine)])/(loading capacity [tonne]*utilisation level) ***The following data was used in the calculations:*** *Assumptions given by the Swedish Road Haulage Association:* -Average fuel consumption: 0,27 l/km. -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1 given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm *The emission factors were: Quantity value, i.e. average engine*: -NOx 6,3 g/kWh -HC 0,4 g/kWh -CO 0,7 g/kWh -Particles 0,11 g/kWh -Degree of efficiency on the engine: 41 % (assumption). The data was supplied by Volvo Truck Corporation. *Maximum value i.e. engine run 500 000 km* The data was supplied by Volvo Truck Corporation and expressed as percentage degeneration in emissions in relation to the average engine. The degeneration factors are based on special degeneration factor tests for EPA/CARB on 12 litre engines. The tests were performed on four engines run 470 000 km. The degeneration factors are an average of the tests. -NOx 6,4 g/kWh - 1,5 % degeneration in relation to the average engine -HC 0,42 g/kWh - 4 % degeneration in relation to the average engine -CO 0,8 g/kWh - 20 % degeneration in relation to the average engine -Particles 0,11 g/kWh - 2 % degeneration in relation to the average engine -Degree of efficiency on the engine: 41 % (assumption) No minimum value was given. *The ECE R49 is a steady state cycle for heavy duty truck engines*. Consists of a sequence of 13 constant engine speed and load modes. Emissions are analysed for each test mode. Then the overall emission result is calculated as a (weighted) average from all test modes. The cycle is characterised by high average engine load and high exhaust gas temperature. Notes: Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially.	Output	Emission	NOx	3.2		3.3	g	Air	
Method: See QMetaData for NOx.	Output	Emission	Particles	0.057		0.059	g	Air	
Date concieved: 1997-01-01 Data type: Derived, unspecified Method: The emission per tonkm was calculated from the fuel consumption using the sulphur content in the diesel ***The following data was used in the calculations:*** *Assumptions given by the Swedish Road Haulage*	Output	Emission	SO2	0.00208		0.00215	g	Air	

Association: -Average fuel consumption 0,27 l/km. -Utilisation level: 70 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 1 given by the Swedish Petroleum Institute:* -Thermal value: 43,43 MJ/kg -Density: 0,81 kg/l -Sulphur content: 10 ppm See QMetaData for the Diesel flow for further information									

About Inventory	
Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Michael Björkman, BTL (Bilspedition Transportation and Logistics), contact person for road transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use. The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal

	The collection and distribution routes are generally performed by smaller vehicles --*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. --*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited --*Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used for transportation in Sweden:*** --*Truck max 3,5 tonnes* is mainly used for transportation of parcels. --*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. --*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. --*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. --*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. --*Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***The Swedish fleet*** The data for different age categories of vehicles (before 92, 1992-1995, after 96) may be used to calculate average energy use and emissions for a specific fleet or the average Swedish fleet of vehicles regarding age distribution. In Sweden, 1996 the following shares of transportation work was carried out by the different age categories: After 1996: 10 % 95-92: 33% Before 1992 52 % The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.
About Data	Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years. The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle

	that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions. A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute. The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Light truck, max 8 tonnes, manufactured before 1992 [Euro 0]

Technical System	
Name	Light truck, max 8 tonnes, manufactured before 1992 [Euro 0]
Functional Unit	1 tonkm, 70 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is representative for Swedish domestic traffic if *empty trips are not included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of a diesel driven light truck with engine manufactured before 1992 (Euro 0 environmental standard). The vehicle is mainly used for local distribution, mainly in city traffic. Maximum gross weight: 8 tonnes. Kerb weight: 5 tonnes. Available loading capacity with regard to weight: 3 tonnes. Length: 7 metres.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents trucks with engine manufactured before 1992
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission factors obtained by the ECE R49 test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level (see specific QMetaData for a description on methods used for each flow). The *quantity value for the energy use* refer to average fuel consumption, the *maximum and minimum value* refer to changes in the efficiency of the engine due to degeneration. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, the quantity value* refer to an average engine guaranteed by Volvo Truck Corporation and the *maximum value* refer to voluntary European emission regulations for diesel engines before 1992.
Literature Reference	Integrated Waste Management - a Life Cycle Inventory, F. McDougall et al, Procter & Gamble Technical Centres Limited, Blackwell Science, 2001 Waste Management International, Landfill Gas Data, Waste Management International, London, 1994 Perry and Green, The Chemical Engineer'sHandbook, McGraw Hill, 1997.
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Michael Björkman, BTL (Bilspedition Transportation and Logistics), contact person for road transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use

	today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.

Reviewer	
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles --*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. --*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited --*Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used for transportation in Sweden:*** --*Truck max 3,5 tonnes* is mainly used for transportation of parcels. --*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. --*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. --*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. --*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. --*Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***The Swedish fleet*** The data for different age categories of vehicles (before 92, 1992-1995, after 96) may be used to calculate average energy use and emissions for a specific fleet or the average Swedish fleet of vehicles regarding age distribution. In Sweden, 1996 the following shares of transportation work was carried out by the different age categories: After 1996: 10 % 95-92: 33% Before 1992 52 % The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions.

	Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.
About Data	Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years. The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions. A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute. The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Light truck, max 8 tonnes, manufactured between 1992 and 1995 [Euro1]

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Light truck, max 8 tonnes, manufactured between 1992 and 1995 [Euro1]
Functional Unit	1 tonkm, 70 %

Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 70 %. An utilisation level of 70 % is representative for Swedish domestic traffic if *empty trips are not included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of a diesel driven light truck with engine manufactured between 1992 and 1995 (Euro 1 environmental standard). The vehicle is mainly used for local distribution, mainly in city traffic. Maximum gross weight: 8 tonnes. Kerb weight: 5 tonnes. Available loading capacity with regard to weight: 3 tonnes. Length: 7 metres.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents trucks with engine manufactured between 1992 and 1995
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 70 % which is representative for Swedish domestic traffic if *empty trips are not included.* *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission factors obtained by the ECE R49 test cycle, together with assumptions on the efficiency of the engine, fuel consumption, type of fuel used and utilisation level (see specific QMetaData for a description on methods used for each flow). The *quantity value for the energy use* refer to average fuel consumption, *the maximum and minimum value* refer to changes in the efficiency of the engine due to degeneration. The emissions of CO2 and SO2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, the quantity value* refer to an average engine guaranteed by Volvo Truck Corporation and the *maximum value* refer to the emission regulations for diesel engines according to the emission standard Euro I.
Literature Reference	Integrated Waste Management - a Life Cycle Inventory, F. McDougall et al, Procter & Gamble Technical Centres Limited, Blackwell Science, 2001 Waste Management International, Landfill Gas Data, Waste Management International, London, 1994 Perry and Green, The Chemical Engineer'sHandbook, McGraw Hill, 1997.

Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology

	Documentation reviewed by: Michael Björkman, BTL (Bilspedition Transportation and Logistics), contact person for road transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Björkman, Michael - BTL (Bilspedition Transportation and Logistics), 412 97 Göteborg .
Reviewer	
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. ***Handling of goods*** Road transports generally consists of 1-3 routes: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles *--Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. *--General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited *--Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used for transportation in Sweden:*** *--Truck max 3,5 tonnes* is mainly used for transportation of parcels. *--Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. *--Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. *--Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. *--Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. *--Truck with semitrailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for a utilisation level of 70 % which is representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than independent firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*.

	During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***The Swedish fleet*** The data for different age categories of vehicles (before 92, 1992-1995, after 96) may be used to calculate average energy use and emissions for a specific fleet or the average Swedish fleet of vehicles regarding age distribution. In Sweden, 1996 the following shares of transportation work was carried out by the different age categories: After 1996: 10 % 95-92: 33% Before 1992 52 % The data was given by SIKA and SCB and concern vehicles larger than 3,5 tonnes. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (about 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbohydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the system. NGM propose that data from Blinge et al Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997 should be used. This study is based on best available technology and Swedish conditions. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. Generally the fleets in Europe is composed of older vehicles. The utilisation of the vehicles may also vary in different countries.
About Data	Several parameters that have a large influence on the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Also, no considerations have been taken for differences in fuel consumption between different age models of vehicles. The fuel consumption for newer models are however lower. According to Greger Juhlin at Scania, the fuel consumption for heavy trucks in highway traffic has decreased from 5,7 l/km to 4 l/km during the last 15 years. The data on emissions is largely based on tests on the engine performed in a laboratory according to a *standardised test cycle*. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle that was used (ECE R49) is developed to represent long-distance traffic. The test cycle is thus not representative for traffic situations with extensive variations on the load conditions. A sulphur content of 10 ppm in the fuel are assumed in the calculations, which is the maximum allowed sulphur content for diesel environmental class 1. The average sulphur content in the fuel sold in Sweden is however lower: 2 ppm +/- 0,5 ppm according to the Swedish Petroleum Institute. The model to calculate the emissions may be used to represent a specific transport or firm of haulage contractors if the age of the vehicle, the fuel use for the transport, the distance and the utilisation level is known (see QMetaData).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Lignite electricity energy system, EPD-version

Administrative	
Finished	Y
Date Completed	1996-10
Copyright	Bundesamt für Energie, Bern
Availability	Public

Technical System	
Name	Lignite electricity energy system, EPD-version
Functional Unit	1 TJ net electricity from power plant
Functional Unit Explanation	The generation of 1 TJ (1 000 000 000 000 J) net electricity (i.e. electricity need in the power plant has been supplied for by the plant itself). Electricity distribution and distribution losses are not accounted for, i.e. not for this particular unit process. Data about distribution and its losses may however be found in the original study.
Process Type	Cradle to grave
Site	UCTPE countries Europe
Sector	Grid electricity and district heat
Owner	UCTPE countries Europe
Technical system description	Reported figures are based on data from a LCI-study performed at ETH, Zürich and Paul Scherrer Institut, Villigen, ''Ökoinventare von Energiesystemen'', 3rd edition 1996 and adapted to the demands of the EPD-guidelines (Environmental Product Declaration guidelines in Sweden). -- Brief description -- The main phases inventoried in ETH's life cycle study of electricity generation with lignite are: mining, transports and power plant operation. Data has been aquired from literature and figures concerning consumption of energyware and materials, use of land and water, emissions to air (also radioactive) and water and wastes have been picked out from or calculated based on literature for all phases of the life cycle. All subsystems are described on a ''cradle-to-grave'' basis, including the main stages, i.e. data concerning consumption of resources, waste handling and emissions is included for the manufacturing of main materials and energyware used in the lifecycle. -- Detailed description -- Mining The prospecting of lignite implies test drillings etc but is not inventoried separatly since only a few millimeters of drilling per tonne lignite is needed. Mining depths are mostly less than 200 m but may reach 600 m. Noise (not quantified in this study), radioactive radon, methane and particles are process specific emissions to air and subsoilwater to water. Open pit mining (94% of used lignite in UCPTE) is studied. For the UCPTE average underground mining has been estimated and added. Two to six times the amount of lignite must be dug out, i.e. large strong mashines are needed. Mainly electrified mobile machines are used, often supplied by a nearby lignite power plant (but UCPTE electricity generation mix has been used in the calculations) but also diesel driven machines. Lower heating value of lignite used in UCPTE power plants has an average of 7,9 GJ/tonne lignite. The subsoil water level must be lowered below the seam. Construction and operation of mines have been inventoried. Demolition processes imply depositing of wood and concrete and metalscrap is assumed to be transported to recycling plants. Transports Extracted lignite is transported to nearby power plants on feeder bands, by lorry or train. No processing of lignite is needed. Power plant Construction and area use has been inventoried for two standard plants (100 and 500 MWe). The smaller standard plant is equiped with electrofilter and wet desulphuring with lime or limestone, the larger plant has a SCR de-NOx device as well. 70% of the UCPTE lignite power plants belong to the 500 MWe class. Combined heat and power is not studied,

	i.e. all generated electricity is supposed to come from lignite condensing plants (electricity from CHPs is less than 5% of UCPTE electricity generation). The plants are base load power plants with an average of 6000 h of operation per year. Furnace technology is conventional (i.e. no gasifyers or fluid beds). Average efficiencies of UCPTE power plants have been calculated (30.9%) based on national statistics. Incoming coal (average heating value 8 MJ/kg) is mixed, grinded and dried. Furnace temperatures of 1,300°C giving fly ashes or 1,600°C leading to ash melting are used. Concerning conventional emissions to air national statistics and bottom-up calculations based on existing UCPTE power plants have been used. Emissions of trace elements are estimated and other emissions are calculated based on literature data. Leaching of substances from deposited ashes is included. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.

System Boundaries

Nature Boundary	Used materials and energyware have been followed from extraction and processing of natural resources. Maufacturing processes for the use of recycled material are accounted for. Emissions from energyware use in manufacturing processes and transports (infrastructure and vehicle construction included) are considered as well as emissions from landfills (infrastructure included) where waste material is disposed of. Waste material supposed to be recycled are outputs of the system (i.e. those recycling processes are not included). ETH's LCI-results comprise all parameters received during inventory and calculation, i.e. no selection has been made by ETH. Vattenfall's criterion in selecting and aggregating ETH's LCI-results for electricity generation in the UCPTE region has been to make the figures usable as general electricity LCI data in EPDs according to Miljöstyrningsrådets guidelines. Especially parameters (emissions) which have established impact indices - accepted by the EPD system - for one or several environmental impact categories, have been picked out and aggregated as far possible. But also metal and energyware resources have been included, as well as waste, in spite of all waste handling processes related to this dataset being included with respect to use of resources and emissions. The latter is an adaption to other LCI data for electricity generation where waste amounts are reported (since those flows have not been followed to the grave). Since ETH claimes that most of the figures regarding metal emissions have an undefined amount of datagaps all metal emissions are aggregated except for a few which are specified separatly since they are reported for most processes in the lifecycle. Metals are reported as elements although they often are part of compounds. Measuring methods often just give the amounts of the different elements found. All hydrocarbons to water are aggregated to one parameter as well as halogenated organics, since no indices exist (that are accepted by the EPD system so far) for characterisation of the individual substances.
Time Boundary	Most background data refer to the period 1990 to 1994. Concerning flue gas cleaning equipment data from 1995/96 has been used where possible. Figures regarding use of materials and mining and processing of coal are older which probably doesn´t affect the result much. Future emissions from deposits for filter ashes are included. Power plant operation is based on the year 1994. Electricity used during the lifecycle has been assumed to be a mix based on the average generation in the UCPTE* countries between 1990-94 (to level off the large variations in hydro power production over the years). All processes, also those conducted in the past, have been assumed to use average technology of the early nineties. Different technical lifetimes/reference times for different parts and materials of the studied systems have been used as follows: Equipment in mines 30 years Power plant 30 years * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Geographical Boundary	Figures are based on average lignite power plants in Austria, Germany, Spain, Ex-Jugoslavia, France and Greece. Lignite mining has been studied in the UCPTE since less than 1% is imported. 67% of lignite used in UCPTE is mined in Germany. Processes conducted outside the UCPTE* region are supposed to be supplied with UCPTE*

	electricity. Data concerning the use of resources, emissions and waste in connection with manufacturing processes mainly originate from sources in Switzerland, Germany and other western European countries. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Other Boundaries	Data concerning material and energyware use in the construction phase of the mine are rough estimates based on a few real mines. Process specific (i.e. not energyware related) emissions to air from mines have not been included except for radon, methane and particles. The flow of substances in subsoil water is not complete. Use and emissions of lubricating and hydraulic oil is not included. Losses of lignite in the mining area has not been accounted for. Losses of lignite during transport or reloading has not been accounted for. Accidents and filter failures are not considered in the power plant. Most data concerning the power plant are based on assumptions and estimates. Manufacturing processes of components and machines have been approximated with 50% of the energyware used to produce contained materials. Energyware figures concerning material production come from literature and have assumed to be a mix of 10% UCPTE electricity, 45% oil and 45% natural gas. This approximation has been confirmed in more thorough calculations in ETH:s LCA for coal power. The ETH study comprises figures concerning use of land, usable content in water storages and amount of turbine water which have not been reported here. The two latter have been excluded due to lack of corresponding data in comparable studies. Use of land has been excluded here because of ETH's advanced approach. Land is divided into two main groups - land and sea - which are subdivided into 4 categories each. Land Criterion Category Natural human impact not larger than other species' since the indutrial revolution I Modified human impact larger than other species', low degree of culivation II Cultivated human impact larger than other species', large degree of cultivation III Built upon dominated by buildings, roads, dams, mines etc. IV Category I is not used in the study. State of land before, during and after exploitation is of intererst. If a piece of land is used again after some kind of exploitation it will either end up in the same category or in a higher one. ETH takes into account not only the land used during the technical lifetime of the studied system but also during the construction phase and during the time it takes to restore the land. They express use of land in the unit m2year which is different from comparable Swedish studies (m2). See times for restoration of land below: From category IV to category III 5 years From category III to category II 50 years From category II to category I 100 000 years (For uranium mines the restoration time to category II is 80'000 years due to elevated radiation caused by long-living radioactive compounds.) ETH specifies about 160 radioactive isotopes emitted to air and water. Radioactive emissions reported here are picked out in accordance with SETAC working group report on data quality and data availability (to be published in 2001). Big accidents occuring seldomly are not included.The threshold is fixed at 10 accidents per year if one energy carrier/system (e.g. oil) would cover the entire primary energy demand of the world.
Allocations	The cutoff-method has been used for material use, i.e. 100% of the environmental load for virgin and recycled material used in the lifecycle is included whereas no environmental load has been considered for materials leaving the system to be recycled. Landfill processes and waste incineration, however, are included for waste arising during the lifecycle.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1985 to 1995
Data Type	Derived, unspecified
Represents	Average electricity generation with lignite in the UCTPE countries.

Method	The data has been adapted from the Ökoinventare von Energiesystemen, ETH Zürich 1996 and is an aggregation of the LCI results for the module ''electricity of lignite power plant UCPTE'' (Strom ab Braunkohlekraftwerk UCPTE-Mix).
Literature Reference	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz, Environmental Life-Cycle Inventories of Energy Systems An Environmental Database for the Accounting of Energy Consumption in Product Life-Cycle Assessment and the Comparative Assessment of Energy systems Prof. Dr. P. Suter, R. Frischknecht, et al Swiss Federal Institute of Technology, Zürich R. Dones, U. Gantner Paul Scherrer Institute, Villigen/Würenlingen
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

Notes: Internal flow! Infrastructure (resources and emissions) included.	Output	Residue	Highly radioactive waste	1.62E-05			m3	Technosphere	
Notes: Internal flow! Infrastructure (resources and emissions) included, no emissions from landfill assumed. Inert waste deposit is waste at landfill that are inert.	Output	Residue	Inert waste deposit	1.27E+03			kg	Technosphere	
Notes: Internal flow! Infrastructure (resources and emissions) included.	Output	Residue	Low radioactive waste	1.97E-04			m3	Technosphere	
Notes: Internal flow! Infrastructure (resources and emissions) included.	Output	Residue	Medium and low radioactive waste	1.98E-04			m3	Technosphere	
Notes: Internal flow! Infrastructure (resources and emissions) included, as well as emissions from landfill. Reactive waste deposit is waste at landfill that is still reactive.	Output	Residue	Reactive waste deposit	4.70E+04			kg	Technosphere	

Notes: Internal flow! Infrastructure of spreading vehicles and emissions are included. Land farming is a treatment of organic sludge, the sludge is spread on a piece of land and left to degrade. Sometimes plants are grown on the land, but those plants are destroyed.	Output	Residue	Waste in land farming	3.56E+00			kg	Technosphere	
Notes: Internal flow! Infrastructure (resources and emissions) included, as well as emissions from incineration plant.	Output	Residue	Waste to incineration	4.08E-01			kg	Technosphere	

About Inventory

Publication	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz. ETH, Eidgenössische Technische Hochschule, Zürich, Gruppe Energie - Stoffe - Umwelt (ESU), Paul Scherrer Institut, Villigen/Würenlingen, Sektion Ganzheitliche Systemanalysen Available on CD-ROM with full documentation (in German) at http://www.energieforschung.ch. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by (see also Notes): Rolf Frischknecht, ESU-services, Switzerland Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	Original study of ETH: LCA pra
General Purpose	The purpose of the ETH study was to examine a number of energy systems quantitatively and to the same extent with respect to environmental issues during their life cycles. The results can be used in life cycle assessments, as basis information in decisionmaking regarding environmental optimisation or in working with municipal energy plans. Vattenfalls purpose - as a commissioner of putting ETH:s data into Spine format with metadata - is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines. Data is supposed to be used together with IEA statistics about electricity generation mixes in the OECD countries/regions.
Detailed Purpose	ETH:s aim was to describe the average situation in the UCPTE concerning electricity generation with lignite. With the help of assumptions and simplifications following phases of the life cycle are described: mining (open pit), transports and power plant.
Commissioner	BEW, PSEL - Bundesamt für Energiewirtschaft, Projekt- und Studienfonds der Elektrizitätswirtschaft .
Practitioner	Rolf Frischknecht et al - ETH, Eidgenössische Technische Hochschule, Institut für Energietechnik, Zürich and Paul Scherrer Institut, Sektion Ganzheitliche Systemanalyse, Villingen/Würenlingen .
Reviewer	None, see further under notes -
Applicability	Data reported here is supposed to be representative for lignite based elctricity generation in the UCPTE countries in 1994. This set of data is aggregated and documented in accordance with the Swedish EPD-guidelines to be used in combination with IEA statistics concerning electricity generation mixes in OECD countries and regions together with other datasets - based on the ETH study - describing other power generation systems. The EPD-adapted power generation systems in Spine format are named as follows: Fuel gas electricity energy system, EPD-version Biofuel electricity energy system, EPD-version Hydro electricity energy system, EPD-version Lignite electricity energy system, EPD-version Nuclear electricity energy system, EPD-version Stone coal electricity energy system, EPD-version Wind electricity energy system, EPD-version IEA statistics for generation mixes 1998 exist in Spine format for the following 30 countries/regions: OECD total OECD North America OECD Pacific OECD Europe European Union Australia Austria Belgium Canada Czech Rpublic

	Denmark Finland France Germany Greece Hungary Iceland Ireland Italy Japan Korea Luxembourg Mexico Netherlands New Zealand Norway Poland Portugal Spain Sweden Switzerland Turkey United Kingdom United States
About Data	Material manufacturing processes have been inventoried with a low degree of exactitude (except for steel, cement, aluminium, copper, bitumen, and platinum group metals for which rather detailed LCI data are provided). Results are reported with three figures, but it is stated in the original source that this does not mean that accuracy is that high (Part III, p.16). For references and sources of reported figures see further under Function, Nature boundary, Geographical boundaries, Publication, Notes and General metadata.
Notes	Reviewer of this specification of ETH:s data and metadata has been: Dr. Rolf Frischknecht, ESU-services (earlier at ETH) - approval of aggregation of figures and of Vattenfall's interpretation ot the documentation Ann-Christin Pålsson, CPM - review of documentation quality according to the CPM data documentation requirements. The technical committee of the Swedish Environmental Management Council - approval of method and aggregation of parameters Project Management of the ETH study, 3rd edition: Professor, Dr. P. Suter and R. Frischknecht, ETH Editorial staff of the 1st edition: R. Frischknecht, P. Hofstetter, I. Knoepfel, M. Ménard, ETH R. Dones, E. Zollinger, Paul Scherrer Institut Authors of the 1st edition: N. Attinger, T. Baumann, G. Doka, R. Dones, R. Frischknecht, H.-P. Gränicher, C. Grasser, P. Hofstetter, I. Knoepfel, M. Ménard, H. Müller, M. Vollmer, E. Walder, E. Zollinger Authors of the revision, 3rd edition: U. Bollens, S, Bosshart, M. Ciot, L. Ciseri, G. Doka, R. Frischknecht, R Hischier, A. Martin, ETH R. Dones, U. Gantner, Paul Scherrer Institut -- --- Changes made to the data set after publishing in SPINE@CPM--- >>> 6 June 2001: <<< Changes made by Ann-Christin Pålsson, CPM, based on discussions with Caroline Setterwall, Vattenfall AB. Comments: The following changes has been made in the nomenclature for in- and outflows: Mangane in ore -> changed to: Manganese in ore CH4 -> changed to: Methane (to be in accordance with the nomenclature specified in CPM report 2000:2) CN -> changed to: CN- Stone coal -> changed to: Hard coal (to be in accordance with the nomenclature specified in CPM report 2000:2) Other metals -> changed to: Metals Explanations of nomenclature (inserted in Notes for the specific flows): - CN- is Cyanide ion - Reactive waste deposit is waste at landfill that is still reactive. - Inert waste deposit is waste at landfill that are inert. Additional clarifications: - Note that the flows of waste in the table of in- and outflows are internal flows, i.e. they do NOT cross the system boundaries. All waste handling processes is included in the study with respect to use of resources and emissions. - Radioactive waste is accounted for in cubic metres. The product specific requirements for electricity and district heating generation (PSR 1998:1) in the Swedish EPD system states that waste shall be accounted for in gram. However, no conversion factors were given in the study.

	There are also no general conversion factors that are commonly used.

Technical System	
Name	Lignite electricity energy system, ETH - full version
Functional Unit	1 TJ net electricity from power plant
Functional Unit Explanation	The generation of 1 TJ (1 000 000 000 000 J) net electricity (i.e. electricity need in the power plant has been supplied for by the plant itself). Electricity distribution and distribution losses are not accounted for, i.e. not for this particular unit process. Data about distribution and its losses may however be found in the original study.
Process Type	Cradle to grave
Site	UCTPE countries Europe
Sector	Grid electricity and district heat
Owner	UCTPE countries Europe
Technical system description	Reported figures come from a LCI-study performed at ETH, Zürich and Paul Scherrer Institut, Villigen, ''Ökoinventare von Energiesystemen'', 3rd edition 1996. Brief description The main phases inventoried in ETH's life cycle study of electricity generation with lignite are: mining, transports and power plant operation. Data has been aquired from literature and figures concerning consumption of energyware and materials, use of land and water, emissions to air (also radioactive) and water and wastes have been picked out from or calculated based on literature for all phases of the life cycle. All subsystems are described on a ''cradle-to-grave'' basis, including the main stages, i.e. data concerning consumption of resources, waste handling and emissions is included for the manufacturing of main materials and energyware used in the lifecycle. Detailed description Mining The prospecting of lignite implies test drillings etc but is not inventoried separatly since only a few millimeters of drilling per tonne lignite is needed. Mining depths are mostly less than 200 m but may reach 600 m. Noise (not quantified in this study), radioactive radon, methane and particles are process specific emissions to air and subsoilwater to water. Open pit mining (94% of used lignite in UCPTE) is studied. For the UCPTE average underground mining has been estimated and added. Two to six times the amount of lignite must be dug out, i.e. large strong mashines are needed. Mainly electrified mobile machines are used, often supplied by a nearby lignite power plant (but UCPTE electricity generation mix has been used in the calculations) but also diesel driven machines. Lower heating value of lignite used in UCPTE power plants has an average of 7,9 GJ/tonne lignite. The subsoil water level must be lowered below the seam. Construction and operation of mines have been inventoried. Demolition processes imply depositing of wood and concrete and metalscrap is assumed to be transported to recycling plants. Transports Extracted lignite is transported to nearby power plants on feeder bands, by lorry or train. No processing of lignite is needed. Power plant Construction and area use has been inventoried for two standard plants (100 and 500 MWe). The smaller standard plant is equiped with electrofilter and wet desulphuring with

	lime or limestone, the larger plant has a SCR de-NOx device as well. 70% of the UCPTE lignite power plants belong to the 500 MWe class. Combined heat and power is not studied, i.e. all generated electricity is supposed to come from lignite condensing plants (electricity from CHPs is less than 5% of UCPTE electricity generation). The plants are base load power plants with an average of 6000 h of operation per year. Furnace technology is conventional (i.e. no gasifyers or fluid beds). Average efficiencies of UCPTE power plants have been calculated (30.9%) based on national statistics. Incoming coal (average heating value 8 MJ/kg) is mixed, grinded and dried. Furnace temperatures of 1,300°C giving fly ashes or 1,600°C leading to ash melting are used. Concerning conventional emissions to air national statistics and bottom-up calculations based on existing UCPTE power plants have been used. Emissions of trace elements are estimated and other emissions are calculated based on literature data. Leaching of substances from deposited ashes is included. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.

System Boundaries	
Nature Boundary	Used materials and energyware have been followed from extraction and processing of natural resources. Maufacturing processes for the use of recycled material are accounted for. Emissions from energyware use in manufacturing processes and transports (infrastructure and vehicle construction included) are considered as well as emissions from landfills (infrastructure included) where waste material is disposed of. Waste material supposed to be recycled are outputs of the system (i.e. those recycling processes are not included). Land is divided into two main groups - land and sea - which are subdivided into 4 categories each. Land Criterion Category Natural human impact not larger than other species' since the industrial revolution I Modified human impact larger than other species', low degree of cultivation II Cultivated human impact larger than other species', large degree of cultivation III Built upon dominated by buildings, roads, dams, mines etc. IV Category I is not used in the study. State of land before, during and after exploitation is of interest. If a piece of land is used again after some kind of exploitation it will either end up in the same category or in a higher one. ETH takes into account not only the land used during the technical lifetime of the studied system but also during the construction phase and during the time it takes to restore the land. They express use of land in the unit m2year which is different from comparable Swedish studies (m2). See times for restoration of land below: From category IV to category III 5 years From category III to category II 50 years From category II to category I 100 000 years (For uranium mines the restoration time to category II is 80'000 years due to elevated radiation caused by long-living radioactive compounds.) ETH's LCI-results comprise all parameters received during inventory and calculation, i.e. no selection has been made by ETH.
Time Boundary	Most background data refer to the period 1990 to 1994. Concerning flue gas cleaning equipment data from 1995/96 has been used where possible. Figures regarding use of materials and mining and processing of coal are older which probably doesn´t affect the result much. Future emissions from deposits for filter ashes are included. Power plant operation is based on the year 1994. Electricity used during the lifecycle has been assumed to be a mix based on the average generation in the UCPTE* countries between 1990-94 (to level off the large variations in hydro power production over the years). All processes, also those conducted in the past, have been assumed to use average technology of the early nineties. Different technical lifetimes/reference times for different parts and materials of the studied systems have been used as follows: Equipment in mines 30 years Power plant 30 years * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.

Geographical Boundary	Figures are based on average lignite power plants in Austria, Germany, Spain, Ex-Jugoslavia, France and Greece. Lignite mining has been studied in the UCPTE since less than 1% is imported. 67% of lignite used in UCPTE is mined in Germany. Processes conducted outside the UCPTE* region are supposed to be supplied with UCPTE* electricity. Data concerning the use of resources, emissions and waste in connection with manufacturing processes mainly originate from sources in Switzerland, Germany and other western European countries. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Other Boundaries	Data concerning material and energyware use in the construction phase of the mine are rough estimates based on a few real mines. Process specific (i.e. not energyware related) emissions to air from mines have not been included except for radon, methane and particles. The flow of substances in subsoil water is not complete. Use and emissions of lubricating and hydraulic oil is not included. Losses of lignite in the mining area has not been accounted for. Losses of lignite during transport or reloading has not been accounted for. Accidents and filter failures are not considered in the power plant. Most data concerning the power plant are based on assumptions and estimates. Manufacturing processes of components and machines have been approximated with 50% of the energyware used to produce contained materials. Energyware figures concerning material production come from literature and have assumed to be a mix of 10% UCPTE electricity, 45% oil and 45% natural gas. This approximation has been confirmed in more thorough calculations in ETH:s LCA for coal power. Big accidents occuring seldomly are not included.The threshold is fixed at 10 accidents per year if one energy carrier/system (e.g. oil) would cover the entire primary energy demand of the world.
Allocations	The cutoff-method has been used for material use, i.e. 100% of the environmental load for virgin and recycled material used in the lifecycle is included whereas no environmental load has been considered for materials leaving the system to be recycled. Landfill processes and waste incineration, however, are included for waste arising during the lifecycle.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1985 to 1995
Data Type	Derived, unspecified
Represents	Average electricity generation with lignite in the UCTPE countries.
Method	The figures have been copied from the module ''Electricity of lignite power plant UCPTE'' (Strom ab Braunkohlekraftwerk UCPTE-Mix) in the Ökoinventare von Energiesystemen, ETH Zürich 1996.
Literature Reference	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz, Environmental Life-Cycle Inventories of Energy Systems An Environmental Database for the Accounting of Energy Consumption in Product Life-Cycle Assessment and the Comparative Assessment of Energy systems Prof. Dr. P. Suter, R. Frischknecht, et al Swiss Federal Institute of Technology, Zürich R. Dones, U. Gantner Paul Scherrer Institute, Villigen/Würenlingen
Notes	Multiple flows are reported for several emissions to air. This is because that in the original study emissions to air have been reported in three categories, indicated by one of the letters below following the substance name. - m = mobile (emissions from vehicles) - p = process (process specific emissions as for instance methane emissions during coal mining) - s = stationary (emissions from stationary combustion plants) This categorisation has however not been documented in this specification in the SPINE format.

About Inventory

Publication	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz. ETH, Eidgenössische Technische Hochschule, Zürich, Gruppe Energie - Stoffe - Umwelt (ESU), Paul Scherrer Institut, Villigen/Würenlingen, Sektion Ganzheitliche Systemanalysen Available on CD-ROM with full documentation (in German) at http://www.energieforschung.ch. --- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by (see also Notes): Rolf Frischknecht, ESU-services, Switzerland Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden ---
Intended User	Original study of ETH: LCA pra
General Purpose	The purpose of the ETH study was to examine a number of energy systems quantitatively and to the same extent with respect to environmental issues during their life cycles. The results can be used in life cycle assessments, as basis information in decisionmaking regarding environmental optimisation or in working with municipal energy plans.
Detailed Purpose	ETH:s aim was to describe the average situation in the UCPTE concerning electricity generation with lignite. With the help of assumptions and simplifications following phases of the life cycle are described: mining (open pit), transports and power plant.
Commissioner	BEW, PSEL - Bundesamt für Energiewirtschaft, Projekt- und Studienfonds der Elektrizitätswirtschaft .
Practitioner	Rolf Frischknecht et al - ETH, Eidgenössische Technische Hochschule, Institut für Energietechnik, Zürich and Paul Scherrer Institut, Sektion Ganzheitliche Systemanalyse, Villingen/Würenlingen .
Reviewer	None, see further under notes -
Applicability	Data reported here is supposed to be representative for lignite based elctricity generation in the UCPTE countries in 1994.
About Data	Material manufacturing processes have been inventoried with a low degree of exactitude (except for steel, cement, aluminium, copper, bitumen, and platinum group metals for which rather detailed LCI data are provided). Results are reported with three figures, but it is stated in the original source that this does not mean that accuracy is that high (Part III, p.16). For references and sources of reported figures see further under Function, Nature boundary, Geographical boundaries, Publication, Notes and General metadata.
Notes	Reviewer of this specification of metadata describing the ETH study has been: Dr. Rolf Frischknecht, ESU-services (earlier at ETH) - approval of Vattenfall's interpretation ot the documentation Ann-Christin Pålsson, CPM - review of documentation quality according to the CPM data documentation requirements. Project Management of the ETH study, 3rd edition: Professor, Dr. P. Suter and R. Frischknecht, ETH Editorial staff of the 1st edition: R. Frischknecht, P. Hofstetter, I. Knoepfel, M. Ménard, ETH R. Dones, E. Zollinger, Paul Scherrer Institut Authors of the 1st edition: N. Attinger, T. Baumann, G. Doka, R. Dones, R. Frischknecht, H.-P. Gränicher, C. Grasser, P. Hofstetter, I. Knoepfel, M. Ménard, H. Müller, M. Vollmer, E. Walder, E. Zollinger

	Authors of the revision, 3rd edition: U. Bollens, S, Bosshart, M. Ciot, L. Ciseri, G. Doka, R. Frischknecht, R Hischier, A. Martin, ETH R. Dones, U. Gantner, Paul Scherrer Institut

SPINE LCI dataset: Limestone quarrying. ESA-DBP

Administrative	
Finished	Y
Date Completed	1996
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Limestone quarrying. ESA-DBP
Functional Unit	1kg of limestone
Functional Unit Explanation	Unknown
Process Type	Gate to gate
Site	Unknown
Sector	Mining and quarrying
Owner	Unknown
Technical system description	Excerpt from the report, see 'Publication': ''The process step to get limestone include excavation, crushing, grinding, sieving, washing and drying''. The input for the process is a limestone rock. This process is included in the system described in: Thuresson J. (1996). Life Cycle Assessment of Water Pumps. Technical Environmental Planning, Report 1996:11 ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Other processes in the CPM Database also included in the above publication: - Coal mining and cleaning. ESA-DBP - Cast iron production. ESA-DBP - Sand extraction and processing. ESA-DBP - Sinter plant's process ESA-DBP - Uranium ore extraction and enrichment. ESA-DBP - Production of pig iron - blast furnace process. ESA-DBP

Systems Expansions	Not applicable

Flow Data	
General Activity QMetaData	
Date Conceived	1994

Data Type	Derived, unspecified
Represents	See 'Function'
Method	Adapted from the other report.
Literature Reference	Thuresson J. (1996). Life Cycle Assessment of Water Pumps. Technical Environmental Planning, Report 1996:11 ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Data for particular process come from: Landbank Environmental Research & Consulting (1994), The Phosphate Report, Landbank
Notes	Multiple flows are reported for several emissions to air. This is because that in the original study emissions to air have been reported in three categories, indicated by one of the letters below following the substance name. - m = mobile (emissions from vehicles) - p = process (process specific emissions as for instance methane emissions during coal mining) - s = stationary (emissions from stationary combustion plants) This categorisation has however not been documented in this specification in the SPINE format.

About Inventory

Publication	Thuresson J. (1996). Life Cycle Assessment of Water Pumps. Technical Environmental Planning, Report 1996:11 ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden.
Intended User	LCA practitioner
General Purpose	Excerpt from the report, see 'Publication': ''The aim of the study is to undertake an LCA of typical water and sewage pumps. Those aspects which have a major contribution to the environmental impact in the life cycle of a pump will be identified.''
Detailed Purpose	Limestone is needed to produce sinter which is the input for pig iron production. Pig iron is then processed into cast iron which is a main material in a water pump (90%).

SPINE LCI dataset: Linoleum flooring. ESA-DBP

Administrative

Finished	Y
Date Completed	1994
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public.

Technical System

Name	Linoleum flooring. ESA-DBP
Functional Unit	1 m2*year flooring
Functional Unit Explanation	Excerpt from the publication (see 'Publication'): ''The purpose of the study was to assess and compare the environmental impact from cradle to grave for floor coverings. The covering of one square metre of flooring during one year of operation was therefore chosen as the functional unit, or basis of comparison.'' 1 m2 of linoleum floor weighs 2.556 kg, including laying waste.
Process Type	Cradle to grave
Site	Not applicable
Sector	Construction
Owner	Not applicable
Technical system description	Excerpt from the publication: ''The life cycle of linoleum. Linseed oil, which is the most important raw material in the actual linoleum paste, acts as a binder. The oil is catalytically oxidised and polymerised with air in large tanks. This produces linoxyn, a reddish-brown highly elastic mass. The hnoxyn is then mixed with resin from coniferous trees, known as colophonium. The mixed linoxyn and resin form a cement, which is left to mature. The cement is then mixed with powdered cork, powdered wood, powdered limestone and pigment. Powdered wood and cork are used to give the sheeting resiliance, and powdered limestone is used as a mineral filler. In linoleum, titanium dioxide is used as the main pigment. After the mixing process, a homogeneous linoleum mass is obtained, which is then converted into granules. The granules are fused to backing, made from jute, under pressure and heat. The still soft sheeting is hung up in long loops in drying rooms to mature further, and is left there for two to three weeks. As the last stage of manufacture the sheets are coated with a thin layer of acrylate. After this has been done, the sheeting is trimmed and rolled. and after packaging it is ready for sale. The production chain takes four to six weeks.'' The flow chart for linoleum flooring can be found at page 247 in the publication. This system is described in: Jönsson et al, 1997, Life cycle assessment of flooring materials: case study. Building and Environment, Vol. 32, No. 3, pp. 245-255. Link to pdf: http://cpmdatabase.cpm.chalmers.se/DataReferences/Joensson_et_al_1997.pdf Other processes in the CPM Database also included in the above publication: Vinyl flooring. ESA-DBP Solid wood flooring. ESA-DBP Other processes in the CPM Database connected to the above publication: Dioctyl phthalate (DOP) production. ESA-DBP

System Boundaries

Nature Boundary	Not applicable.
Time Boundary	Data are applicable to the situation at the time, i.e. 1994.
Geographical Boundary	The scenarios describe a Swedish situation. The linoleum studied was produced in the Netherlands.

Other Boundaries	Excerpts from the publication (see 'Publication'): - Floorings for domestic use were studied. - It was assumed for the calculations that there is no recycling or recovery of the flooring materials, and that all materials are incinerated, with energy recovery, after use. - It was assumed that all pigments used consisted of titanium dioxide. - Some additives in the products were used in such small quantities that their environmental impact was disregarded in the study.
Allocations	Excerpt from the publication (see 'Publication'): ''The environmental impact of multi-output processes was allocated in proportion to the physical parameter most closely reflecting the economic value, which in most cases resulted in weight being used. No allocation was made between the two functions of incineration, waste elimination and heat production. Instead, the heat produced was reported as a useful energy flow leaving the systems analysed.''
Systems Expansions	Not applicable.

About Inventory

Publication	Jönsson et al, 1997, Life cycle assessment of flooring materials: case study. Building and Environment, Vol. 32, No. 3, pp. 245-255. Link to pdf: http://cpmdatabase.cpm.chalmers.se/DataReferences/Joensson_et_al_1997.pdf
Intended User	LCA practitioners.
General Purpose	Excerpts from the publication (see 'Publication'): ''The consequences of the human impact on the environment have become increasingly clear in recent years. A number of previously unknown environmental problems have emerged at local, regional and global levels, in spite of considerable efforts to decrease environmental emissions from identified point sources. Consequently, demands are now being made on the environmental soundness of products. From industry there is a demand for methods of improving products from the environmental point of view, both for internal use and for marketing purposes. Authorities need methods which can be used to assess the environmental consequences of product related decisions. Life cycle assessment (LCA) is becoming an increasingly important method for making product related environmental assessments.'' ''When applying LCA to building materials and components, special methodological problems arise because of the relatively long lifetime and the complex purpose of these products. Therefore, a project entitled ''Environmental Assessment of Buildings and Building Materials'' has been initiated at the Department of Technical Environmental Planning of Chalmers University of Technology (CTH). The case study of flooring materials presented in this article constitutes the first step in this project.''
Detailed Purpose	Excerpt from the publicatoin (see 'Publication'): ''The environmental impact of three flooring materials during their life cycles was assessed and compared using the LCA method. The objective was to make a specific comparison between the environmental impacts of the life cycle of some flooring materials and to develop a methodology for LCA of building materials.''
Commissioner	Not applicable - .
Practitioner	Jönsson, Åsa - Technical Environmental Planning Chalmers University ofTechnology Göteborg Sweden .
Reviewer	Tillman, Anne-Marie - Environmental Systems Analysis
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries'.

About Data	Excerpts from the publication (see 'Publication'): '' - The three studied products all have a calorific value and could alternatively be used as fuels. Since the energy recovered from incineration was accounted for as an energy gain, the calorific value of the materials was treated as an energy cost. - Production of electricity was not included in the systems analysed, due to lack of data. Electricity use was thus accounted for only as the amount used. When interpreting the results, the amount of electricity used reflects a number of environmental impacts, including flooded land from hydropower, radioactive waste from nuclear power and emissions to the air from fossil fuel based electricity production. - The environmental impact of cleaning and maintenance was omitted. It was roughly assumed that the cleaning habits are probably independent of what floor covering is used. In addition, no reliable data were available in this area.'' ESA Database Project. Years: 2009-2011. Documentation completed for this data set: 2010-09-15 Administering organisation: Chalmers University of Technology, the division of Environmental Systems Analysis. Financier: The Swedish Research Council. Documentor of data: Filippa Fuhrman (ESA). Review committee for documented data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).

SPINE LCI dataset: Liquid crystal display unit assembly

Administrative	
Finished	Y
Date Completed	2000-03-01
Copyright	Ericsson
Availability	Official

Technical System	
Name	Liquid crystal display unit assembly
Functional Unit	One gram liquid crystal display unit
Functional Unit Explanation	The motivation for choosing this functional unit is: · suitable unit to work with in an LCA of a private branch exchange (a complicated telecom product) · important component of the MD110 product system and many other electronic products. DESIGN Both answers from component manufacturer one (CM1) and component manufacturer two (CM2) are for exactly the same component. These facts are based on Ericsson technical specification of the component. Ericsson product number: RNH 921 409/1 Ericsson description of the display unit: Liquid Crystal Display Module General Display: 40 characters x 3 lines Liquid Crystal Display module Character font: 5x8 dot matrix Technology: FSTN (Film SuperTwisted Nematic) Mode: positive, operates in reflective mode Viewing angle 6 O'clock viewing angle direction Duty cycle: 1:32 Bias: 1:6.7 Interface: 4-bit MPU interface Antiglare: yes Flat cable: yes

	DESIGN RNH 921 409/1 is a display module completed with larger line distance, with driving circuits which are mounted on its PC board. The display module is provided with a flat cable. Height: 38,8 mm Width: 164,4 mm Lenght: 9,5 mm Weight: 72 gram per display according to Ericsson Weight CM1: 76,2 g (106,2 g including packaging material) Weight CM1: 56,9 g
Process Type	Gate to gate
Site	Not relevant
Sector	Manufacturing
Owner	Not relevant
Technical system description	This activity includes the final assembly of a liquid crystal display unit. The activity is an average based on information acquired from two manufacturers. The description of the process is supplied by manufacturer one, but is assumed to be general for this type of manufacture. The following process steps are included; 1. Mother glass patterning 2. Off-set printing: 3. Rubbing 4. Common & seal printing 5. Mother glass assembly 6. Scribing & breaking 7. Liquid crystal injection 8. End seal 9. Cell inspection 10. Polarizer cut & attachment 11. LCD inspection 12. Module assembly with PCB 13. Inspection & packing 14. QA shipment inspection 15. Consignment Details given: 1. Mother glass patterning: The patterning of the mother glass is done through a mask that reproduce the drawing of circuit. 2. Off-set printing: The alignment layer is printed over the mother glass 3. Rubbing: The system uses an high speed rotary roll. 4. Common & seal printing: By a screen printing process the common & seal agent are coated. 5. Mother glass assembly: Front & rear glasses are aligned to dedicated mark patterns. 6. Scribing & breaking: Glass is scribed along separation lines by small roll cutter and broken apart along the scribed lines. 7. Liquid crystal injection: Every cell is filled with liquid crystal (LC) in a vacuum chamber. 8. End seal: The filling hole is covered by an agent. 9. Cell inspection: Appearance & functional tests are carried out. 10. Polarizer cut & attachment: Front & rear polarizers are cut and attached to the cell. 11. LCD inspection: Appearance & functional tests are carried out. 12. Module assembly with PCB: LCD is assembled with frame, PCB and rubber connectors. 13. Inspection & packing: Products are inserted in plastic bags and included in inner boxes. 14. QA shipment inspection: Further tests are carried out. 15. Consignment: Products are packed inside master carton and shipped accordingly. Manufacturer two did not give any information about process steps. Additional information from manufacturer one (CM1): The annual production of liquid crystal display units is 180 000 pieces. A module is composed by the glass display and the electronic driving board assembled with a metal frame. More than 70% of the organic thinners (acetone and other ketones and alcohols) are

	recovered at the liquid state and wasted by an authorized service supplier. The recovery inside the factory is included by this supplier in the activity. The process water containing acid, salt and hydroxides are treated in a specific facility before sent into a river. The wastewater treatment are not included in the activity. There are two energy sources involved. The electric energy is used to run the machines and for the process ovens. The natural gas is used for the air conditioning and heating system. The concentration of the organic solvent in the air exhaust is periodically checked in the pipes by the Government Control Service. The quality of the wastewater is periodically checked the Government Control Service.

System Boundaries

Nature Boundary	The emissions to air have nature as recipient. Each parameter mentioned by the component manufacturers has been studied. No parameter has deliberately been disregarded when environmental impact has been studied. Included component manufacturers have not specified the same parameters. In the cases where only one manufacturer has stated a parameter this has been used. Emissions to water are stated before the wastewater treatment facility.
Time Boundary	1998 The answer from the manufacturer arrived in 1998 and they measured in 1998. The process technology used is most certainly the best available as the factories are located in Italy and Japan and the companies are well established.
Geographical Boundary	The technical system for this model is limited to the factory where the production takes place. The manufacturers included in the average are located in Italy and Japan.
Other Boundaries	Delimitations to the system is the final step in the making of the display unit. The production of the subparts (e.g. polarizer film, gold plated board, and liquid crystal) of the display unit is not included in this model The transportation of them to the factory is not included. For interested parties who wish to include the transport figures given from the manufacturers, can find the figures in the section Applicability. For component manufacturer one, the packaging materials for the incoming raw material have been included.
Allocations	The manufacturers have not described how the allocation has been made. We did not decide or have any suggestions on how the manufacturer should allocate in their factory.
Systems Expansions	None.

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, unspecified
Represents	See 'Function'.
Method	The data that are presented are calculated as a average based on information from two component manufacturers. The information from the manufacturers was acquired using a LCI data questionnaire. The average for each presented flow is calculated as follows: - First the amount of each flow per functional unit is calculated for each component manufacturer - Then the calculated amount for each component manufacturer is summed for each unique flow and divided by the number of included component manufacturers In the information supplied by the manufacturer, they had indicated whether the data for each flow were measured, estimated or calculated. Below is a detailed account of the calculation procedure. Definition of variables: CMn: Component manufacturer number n. Myn: Materials, emission, waste, energy (y) given in component answer n. ACyn: Amount of material y in component, expressed in mg (or similar) by component manufacturer n Wn: Weight of one piece of component, expressed in mg (or similar) by component manufacturer n. Nyn: The flow y expressed per functional unit from manufacturer n. Step 1. For CM1 sum AC1+..+.ACn Step 2: The sum AC11+..+.ACyn = W1 Step 3: Divide all flows between M11...M1n by W1 --> N11...N1n Step 4: Repeat Step 1 to 3 for all component manufacturers and for each flow. Step 5: Sum N1n+..Nyn and divide by the number of terms for each unique flow.(material input, emission etc.) An average calculation like above of up to two answers was made.

Date concieved: 1998 Data type: Derived, unspecified Method: This flow is by one of the manufacturers called ''water treatment mud''. I called it Sludge. Estimated 20000 mg from one manufacturer. 20 g / 106,2093 g = 0,1883074269391 g/g display unit. 106,2093 g is the weight of one display unit according to this manufacturer. This is not an average value and the figure is based only on one answer.	Output	Residue	Sludge	0.1883			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Calculated and estimated from one manufacturer. (2,780 - 2,140)/56,9876 = 0,01123051330465 g Solder cream/g display unit. 56,9876 g is the weight of one display unit according to this manufacturer. 2140 mg is the amount solder paste in product output. 2780 mg is the amount solder paste in raw material input. I assume the rest is waste output. This is not an average value and the figure is based only on one answer.	Output	Residue	Solder cream	0.0112			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Estimated 20000 mg from one manufacturer. 20 g / 106,2093 g = 0,1883074269391 g/g display unit. 106,2093 g is the weight of one display unit according to this manufacturer. Used value: 0,1883 g/g display unit. This is not an average value and the figure is based only on one answer.	Output	Residue	Waste water treatment chemicals	0.1883			g	Technosphere	

About Inventory	
Publication	Not available. --- Data documented by: Anders Andrae, Ericsson Business Networks AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology ---
Intended User	The intended use for this LCI
General Purpose	The general purpose with this LCI model was for application in a LCA project at Ericsson Business Networks. The main goal of the study is; to compare the potential environmental impacts associated with an old (BC 8) and a new model (BC 10) of a private branch exchange (PBX) system, namely the MD110 system, and an additional objective is to include comparisons between different stages of the life cycle (e.g. manufacturing, use and end of life) of the system. The system, PBX MD110, is designed, developed and delivered by Ericsson Enterprise Systems AB. Life-Cycle Assessment methodology (following the ISO14040 standards for LCAs) will be used to determine the environmental impacts. The main purpose of the study for Ericsson is; - to learn, test and evaluate the LCA-methodology as a tool for assessing environmental improvement options in the product design process, and to make up concrete product guidelines regarding design for environment (DfE) and - to evaluate environmental aspects in new design. The relative importance for different life cycle stages may also be an important input in the internal work with an Environmental Management System for Ericsson Enterprise Systems. Another purpose of the study is; to collect and qualify data from suppliers and literature in order to build up a database for this and future LCA activities and within the project, it is also intended to analyse the possibilities to use the study as a base for future work regarding a type III ecolabeling project within Ericsson. The intended audience of the report from the project is; Ericsson's personnel: project management, system management, design, marketing and sales organisation, and thus also (in an extracted version) the Ericsson customers.
Detailed Purpose	Map a display unit manufacturing/assembly process from an environmental standpoint in a structured procedure. The purpose of the project was to collect resource consumption data and emission data connected with the final assembly of display units and resembling components in our telecom products. The usage for this set of data are life cycle assessments where display units are part of the studied system. Note: This model is one of in total eighteen models compiled at Ericsson, describing 16 component groups in the PBX. The division into component groups is based on structural resemblance, electrical function and material contents of the different components. --- Below is a list of the component groups and corresponding models that have been compiled: 1. Cables - Model: Cable assembly 2. Capacitors and filters; hole mounted devices - Model: Capacitor for hole mounting assembly 3. Capacitors; surface mounted devices - Model: Capacitor for surface mounting assembly 4. Connectors and holders - Model: Connector assembly 5. Diodes - Model: Diode wafer production and assembly 6. Display units and indicators - Model: Liquid crystal display assembly 7. Microcircuits, oscillators, quartz crystal units and delay lines (2 models) - Models: 1. Integrated circuit capsule assembly and 2. Si wafer production and Si wafer processing for integrated circuits (these models are interlinked) 8. Other - Model: ''Other'' electronic component assembly 9. Potentiometers - Model: Potentiometer assembly 10. Printed boards - Model: Printed board assembly

	11. Relays - Model: Relay assembly 12. Resistor networks - Model: Resistor network assembly 13. Resistors, varistors and thermistors; hole mounted devices - Model: Resistor for hole mounting assembly 14. Resistors; surface mounted devices - Model: Resistor for surface mounting assembly 15. Transformers and inductors - Model: Inductor assembly 16. Transistors and opto couplers (2 models) - Models: 1. Transistor assembly and 2. Si wafer production and Si wafer processing for transistors (these models are interlinked)

Applicability	This set of data can be applied to display units in electronic equipment if you know how much the display units weigh. The model is also intended to be representative for indicators in electronic equipment. -- Transports.-- Here follows a more detailed description of transports of materials and components to the respective manufacturer factories. These transports are not included in the model. The calculation for all modes of transport is done like this: First the total transportation work per functional unit is calculated for each included component manufacturer. Then the total transportation is summed and divided by the number of included component manufacturers. This gives the average value for transportation by each mode of transport. -- Truck transportation: -- Component manufacturer one (CM1): Glass with weight 30 g is transported 250 km, i.e. 30 g*250 km, Polaricer film 2 g * 250 km, Gold plated board 18 g * 30 km, Stainless steel 14,2 g * 30 km, Silicone rubber 2,2 g * 250 km, El. components 5,5 g * 300 km, PE anti static Bag 3,5 g * 50 km, Carton pack 30 g * 50 km, that is 12841 gkm. Weight of component: 106.2093 g The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives: 12841 gkm/106.2093 g = 120.90 gkm/g Component manufacturer two (CM2): Weight of component: 56.9876 g Glass with weight 11.657 g is transported 400 km by road i.e. 11.657 g*400 km, Liquid crystal 0.25 g*850 km, Polarizers 2.868 g*600 km, Sealing material 0.0097 g*950 km, Coating materials 0.0007 g*450 km, PCB 18.92 g*350 km, LCD driver 4.02 g*800 km, Metal holder 19.05 g*800 km, Zebra rubber connector 3.36 g*600 km, Flat cable 2.8 g*800 km, Resistor, capacitor 0.07 g*800 km and Solder paste 2.78 g*480 km The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives: 35781.31 gkm/56.9876 g = 627.88 gkm/g This gives the average total transportation work by truck for CM1 and CM2: (CM1+CM2)/2= 374.39 gkm/g --Airplane transportation: -- Calculations manufacturer one: 2 grams of polarizer transported 10000 km to the factory 2,2 grams of silicon rubber 10000 km to the factory 5,5 grams of electronic components 10000 km to the factory that is 97000 gkm. 97000 gkm/106,2093 g = 913,29gkm / g display unit

	-- Boat transportation: -- Calculations manufacturer one: Transport by boat: 30 grams of glass transported 18000 km to the factory that is 54000 gkm. 54000 gkm/106,2093 g = 508,43 gkm / g display unit
About Data	The data is based on information from one Italian and one Japanese manufacturer. The information was gathered using a life cycle inventory questionnaire. All flows are not average values and where there were only one manufacturer stating a certain flow, this one was chosen in the model. Of the flows about little more than 79 % are not average values. The flows for Raw material input of Glass, Polarzer film, Photoresist, HCl, Gold plated board, Stainless steel, Electrical components, Liquid crystal polymer and Epoxy resin, Waste output of Glass and Energy input of Electricity are average values. In specific QMetaData for each flow, we have indicated specifically for each flow how many manufacturers have been included. The figures in the original answer from the manufacturers should all have a special tag telling if the value has been calculated, measured or estimated or a combination of two or three of them. Ericsson specifically told the manufacturers to do so. The result is that approximately 22 % of the flows used in all manufacturers answers were only calculated, 10 % were only estimated, 18 % were only measured and 37 % were first estimated and then calculated. 13 % were first measured and then calculated The outline of the LCI data questionnaire that were used in the inventory follows below. No limitations or specifications were set for which substances they had to account -- LCI data questionnaire -- Transport description: Material type, Used weight of Material (g)/functional unit, Transport by road of Material (km), Transport by boat of Material (km), Transport by rail of Material (km). We here only asked for flows exceeded 2% by weight of the material declaration of the component. Additional information was also asked for and here some manufacturers mentioned they had aeroplane transport instead of some of the other transport modes.´ Process description. Description of the entire production at the plant/site and a technical description of the plant production. Description of the production line of the studied product. Flow chart of process steps for production of the studied product. Technical description of the production line. A very short description of each unit operation. Data quality. For every figure you give, give an account on how you gatherd it. C = calculated, E = estimated, M = measured. General LCA-related information on the production system (Allocation procedures, system boundaries, etc.). Additional information. (e.g. planned changes in production rate) Material, components and natural resource input, etc. We told them to express data in amount per functional unit. Name of material, component or resource. Used amount(mg). Amount In Product(mg). Additional information Energy-ware input Energy -ware source. Quantity/functional unit. Unit. Energy-ware supplier, production site (address). Suppliers of transport (address). Additional information. Emissions. Emissions to air. Indicate whether emissions from energy use are included in the data. Name of emission to air. Emission to air/functional unit (mg). Additional information. Emissions to water. Indicate if data describes emissions going to external purification plant or directly to recipient. Name of emission to water. Emission to water/functional unit (mg). Additional information. Emissions to soil.

	Name of emission to soil. Emission to soil/functional unit (mg). Additional information. Waste. Name of waste. Waste/functional unit (mg). Recycled/functional unit (mg). Additional information.

SPINE LCI dataset: Locomotive two-stroke engine

Administrative	
Finished	Y
Date Completed	1996-04-01
Copyright	
Availability	Public

Technical System	
Name	Locomotive two-stroke engine
Functional Unit	1 kWh
Functional Unit Explanation	1 kWh mechanical work done by the engine
Process Type	Unit operation
Site	Sweden
Sector	Machinery and equipment
Owner	Sweden
Technical system description	Operation of a locomotive two-stroke engine.

System Boundaries	
Nature Boundary	Regulated emissions to air are considered.
Time Boundary	The data represents existing engines in use in 1996
Geographical Boundary	The data is based on an engine in use in Sweden.
Other Boundaries	A standardised test cycle on the engine (ECE R49) was used.
Allocations	N/A
Systems Expansions	N/A

Flow Data	
General Activity QMetaData	
Date Conceived	1996-01-01
Data Type	Single sample
Represents	See 'Function'.
Method	The emissions were obtained by tests on one locomotive engine using the standardised test cycle ECE R49 (MTC 96:4). The fuel used in the tests was diesel environmental class 3. The tests give weighted emission index in g/kWh, where kWh refer to mechanical work done by the engine.
Literature Reference	Exhaust emissions from a two stroke locomotive engine, MTC rapport 96:4, Motortestcenter, Svensk Bilprovning, 1996
Notes	Not applicable.

About Inventory

Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by:

	Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998

Technical System	
Name	Maintenance of train bearings - train type 'Regina'. ESA-DBP
Functional Unit	2 axleboxes with bearings on a distance of 100 000km
Functional Unit Explanation	Excerpt from the report, see 'Publication': ''The function of bearings in train wheels is to be the link between wheel axle and train car, and make the axle able to rotate. The functional unit (fu) is here defined as 2 axleboxes with bearings, mounted on a wheel axle in use on its matched Electric Multiple Unit (EMU) during 100 000 km of transport. (...) For the calculations a maintenance interval of 500 000 km is assumed for the bearings, which implies maintenance every fifth year if the EMUs are run 100 000 km per year.''
Process Type	Gate to gate
Site	SKF Sverige AB 415 50 Göteborg
Sector	Land transport
Owner	SKF Sverige AB 415 50 Göteborg
Technical system description	The study was done for a a train 'Regina' which is manufactured by Adtranz, today Bombardier Transportation, since the year 2000. In this kind of train pre-lubricated, sealed Tapered Bearing Units, so-called TBUs are used. The Reginas are used on the Swedish West coast, in Mälardalen and in Bergslagen. Excerpt from the study, see 'Publication': ''The function of bearings in train wheels is to be the link between wheel axle and train car, and make the axle able to rotate. (...) The Regina TBU is named 1639605 C and contains the bearing BT2B 641157 CB. The axlebox has the number 432758. The maintenance interval is of great importance for the analysis of the total environmental impact from the use of train bearings. However, the real maintenance interval is difficult to estimate, as the wheel axles can be sent to refurbishment for various reasons, e.g. misuse, derailment, warm-running, reached recommended maintenance interval etc. There is no statistics on how often the bearings are sent to refurbishment just because of malfunction of the bearings themselves. (...) For the calculations a maintenance interval of 500 000 km is assumed for the bearings, which implies maintenance every fifth year if the EMUs are run 100 000 km per year. For the bearings in Regina (...) the recommended maintenance interval (...) is 1 000 000 km. (...) These figures are based on evaluations of many factors, like climate, speed, lubrication and wheel axle and bearing construction, and do not reflect the performance of the bearings alone. (...) For the maintenance process, there is a number of sub-processes called dismounting of wheel axle, detergent production, naphtha production, lubricating oil and grease production, local processes, and waste oil handling.'' This process is included in the system described in: Jonasson K., Environmental Aspects of the Use-Phase for Bearings in Trains. Environmental Systems Analysis, Report 2003:3, ISSN 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2003--3.pdf Other processes in the CPM Database also included in the above publication: - Operation on train bearings - train type 'X1'. ESA-DBP - Operation on train bearings - train type 'X10'. ESA-DBP - Operation on train bearings - train type 'Regina'. ESA-DBP - Maintenance of train bearings - train type 'X1'. ESA-DBP - Maintenance of train bearings - train type 'X10'. ESA-DBP - Use phase of train bearings - train type 'X1'. ESA-DBP - Use phase of train bearings - train type 'X10'. ESA-DBP - Use phase of train bearings - train type 'Regina'. ESA-DBP

System Boundaries	
Nature Boundary	The emissions to air and water are considered.

Time Boundary	Excerpt from the report, see 'Publication': ''The study is intended to illustrate the present situation, and the qualitative and quantitative information for the main processes are from the year 2001 until today. (NB: the report was written in 2003)
Geographical Boundary	Sweden
Other Boundaries	Excerpt from the report, see 'Publication': ''The environmental effects of industrial buildings, production of tools and machines, and the use of human labour are not included. (...) For the calculations a maintenance interval of 500 000 km is assumed for the bearings, which implies maintenance every fifth year if the EMUs are run 100 000 km per year.''
Allocations	Unknown
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	2001
Data Type	Derived, unspecified
Represents	See 'Function'
Method	The data for dismounting and refurbishment were taken from the sites where the process takes place. Data for detergent, oil and transport were take from existing databases.
Literature Reference	Jonasson K., Environmental Aspects of the Use-Phase for Bearings in Trains. Environmental Systems Analysis, Report 2003:3, ISSN 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://www.cpm.chalmers.se/CPMDatabase/DataReferences/ESA_2003--3.pdf
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

	http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2003--3.pdf
Intended User	LCA practitioner
General Purpose	Excerpt from the report, see 'Publication': ''The goal of this LCA is to investigate the environmental impact of the use-phase for bearings in trains. Three generations of trains, so-called Electrical Multiple Units (EMUs), will be studied, and comparison will be made between processes within the life cycle of the bearings, and between the bearings in the different generations of EMUs.''
Detailed Purpose	Maintenance of the bearings has a great importance in a use phase so it was necessary to investigate its impact.
Commissioner	SKF Sverige AB - 415 50 Göteborg .
Practitioner	Karl Jonasson - .
Reviewer	Björn Andersson, - Environmental Systems Analysis, Chalmers University of Technology
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	Excerpt from the report, see 'Publication': ''SKF provides both bearings and bearing housings for trains, called axleboxes, which are mounted in direct connection with the train's wheels to make the wheel axle able to rotate (...). The bearings used for this purpose are in this study referred to as 'train bearings', even though there are other fields of application for bearings in trains (e.g. in the traction system). What type of rolling bearings used for the wheel axle varies according to performance needs and train design, but the function is essentially the same.''

Technical System	
Name	Maintenance of train bearings - train type 'X1'. ESA-DBP
Functional Unit	2 axleboxes with bearings on a distance of 100 000km
Functional Unit Explanation	Excerpt from the report, see 'Publication': ''The function of bearings in train wheels is to be the link between wheel axle and train car, and make the axle able to rotate. The functional unit (fu) is here defined as 2 axleboxes with bearings, mounted on a wheel axle in use on its matched Electric Multiple Unit (EMU) during 100 000 km of transport. (...) For the calculations a maintenance interval of 500 000 km is assumed for the bearings, which implies maintenance every fifth year if the EMUs are run 100 000 km per year.''
Process Type	Gate to gate
Site	SKF Sverige AB 415 50 Göteborg
Sector	Land transport
Owner	SKF Sverige AB 415 50 Göteborg

Technical system description	The study was done for a a train 'X1' which was manufactured by ASEA during the years 1967-1975. In this kind of train an un-sealed Spherical Roller Bearings (SRBs) were used. More than 100 of X1s were produced and most of them are still in use especially in Stokholm area. Excerpt from the study, see 'Publication': ''The function of bearings in train wheels is to be the link between wheel axle and train car, and make the axle able to rotate. (...) The SRB used in X1-A, X1-B and X10 has the SKF product number 23226 CC/C3W33, and the axleboxes are called 723724, 723721 and 4000850 respectively. The maintenance interval is of great importance for the analysis of the total environmental impact from the use of train bearings. However, the real maintenance interval is difficult to estimate, as the wheel axles can be sent to refurbishment for various reasons, e.g. misuse, derailment, warm-running, reached recommended maintenance interval etc. There is no statistics on how often the bearings are sent to refurbishment just because of malfunction of the bearings themselves. (...) For the calculations a maintenance interval of 500 000 km is assumed for the bearings, which implies maintenance every fifth year if the EMUs are run 100 000 km per year. For the bearings in X1 (...) the recommended maintenance interval (...) is 1 200 000 km. (...) These figures are based on evaluations of many factors, like climate, speed, lubrication and wheel axle and bearing construction, and do not reflect the performance of the bearings alone. (...) For the maintenance process, there is a number of sub-processes called dismounting of wheel axle, detergent production, naphtha production, lubricating oil and grease production, local processes, and waste oil handling.'' This process is included in the system described in: Jonasson K., Environmental Aspects of the Use-Phase for Bearings in Trains. Environmental Systems Analysis, Report 2003:3, ISSN 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2003--3.pdf Other processes in the CPM Database also included in the above publication: - Operation on train bearings - train type 'X1'. About Inventory

Publication	Jonasson K., Environmental Aspects of the Use-Phase for Bearings in Trains. Environmental Systems Analysis, Report 2003:3, ISSN 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2003--3.pdf
Intended User	LCA practitioner
General Purpose	Excerpt from the report, see 'Publication': ''The goal of this LCA is to investigate the environmental impact of the use-phase for bearings in trains. Three generations of trains, so-called Electrical Multiple Units (EMUs), will be studied, and comparison will be made between processes within the life cycle of the bearings, and between the bearings in the different generations of EMUs.''
Detailed Purpose	Maintenance of the bearings has a great importance in a use phase so it was necessary to investigate its impact.
Commissioner	SKF Sverige AB - 415 50 Göteborg .
Practitioner	Karl Jonasson - .
Reviewer	Björn Andersson, - Environmental Systems Analysis, Chalmers University of Technology
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet)

	Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	Excerpt from the report, see 'Publication': ''SKF provides both bearings and bearing housings for trains, called axleboxes, which are mounted in direct connection with the train's wheels to make the wheel axle able to rotate (...). The bearings used for this purpose are in this study referred to as 'train bearings', even though there are other fields of application for bearings in trains (e.g. in the traction system). What type of rolling bearings used for the wheel axle varies according to performance needs and train design, but the function is essentially the same.''

Technical system description	The study was done for a a train 'X10' which was manufactured by ASEA/ABB Traction during the years 1982-1993. In this kind of train an un-sealed Spherical Roller Bearings (SRBs) were used. More than 100 of X10s were produced and most of them are still in use especially in Stokholm, Gotheburg and Skåne area. Excerpt from the study, see 'Publication': ''During the 1990s some of the X10s were rebuilt with a different interior, and renamed to X11. These are also included under the designation X10 in this study, as the basic performance is the same. (...) The function of bearings in train wheels is to be the link between wheel axle and train car, and make the axle able to rotate. (...) The SRB used in X1-A, X1-B and X10 has the SKF product number 23226 CC/C3W33, and the axleboxes are called 723724, 723721 and 4000850 respectively. The maintenance interval is of great importance for the analysis of the total environmental impact from the use of train bearings. However, the real maintenance interval is difficult to estimate, as the wheel axles can be sent to refurbishment for various reasons, e.g. misuse, derailment, warm-running, reached recommended maintenance interval etc. There is no statistics on how often the bearings are sent to refurbishment just because of malfunction of the bearings themselves. (...) For the calculations a maintenance interval of 500 000 km is assumed for the bearings, which implies maintenance every fifth year if the EMUs are run 100 000 km per year. For the bearings in X10 (...) the recommended maintenance interval (...) is 648 000 km. (...) These figures are based on evaluations of many factors, like climate, speed, lubrication and wheel

	axle and bearing construction, and do not reflect the performance of the bearings alone. (...) For the maintenance process, there is a number of sub-processes called dismounting of wheel axle, detergent production, naphtha production, lubricating oil and grease production, local processes, and waste oil handling.'' Intended User	LCA practitioner
General Purpose	Excerpt from the report, see 'Publication': ''The goal of this LCA is to investigate the environmental impact of the use-phase for bearings in trains. Three generations of trains, so-called Electrical Multiple Units (EMUs), will be studied, and comparison will be made between processes within the life cycle of the bearings, and between the bearings in the different generations of EMUs.''
Detailed Purpose	Maintenance of the bearings has a great importance in a use phase so it was necessary to investigate its impact.
Commissioner	SKF Sverige AB - 415 50 Göteborg .
Practitioner	Karl Jonasson - .
Reviewer	Björn Andersson, - Environmental Systems Analysis, Chalmers University of Technology
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	Excerpt from the report, see 'Publication': ''SKF provides both bearings and bearing housings for trains, called axleboxes, which are mounted in direct connection with the train's wheels to make the wheel axle able to rotate (...). The bearings used for this purpose are in this study referred to as 'train bearings', even though there are other fields of application for bearings in trains (e.g. in the traction system). What type of rolling bearings used for the wheel axle varies according to performance needs and train design, but the function is essentially the same.''

SPINE LCI dataset: Manufacturing of brass cages at SKFs site in Göteborg

Administrative

Finished	Y
Date Completed	02-12-31

Availability	Public

Technical System	
Name	Manufacturing of brass cages at SKFs site in Göteborg
Functional Unit	One brass cage, 55,6 kg
Functional Unit Explanation	One SKF spherical roller bearing 232/530 consists of following components: 1. one inner ring 2. one outer ring 3. one guide ring 4. one brass cage 5. 36 rollers (coated or non-coated) The functional unit for this process is one brass cage. Note that this is only a subactivity for ''Production of brass cages used for spherical roller bearings''. The total data in the activity ''Production of brass cages used for spherical roller bearings'' can finally be used (together with data for the other ingoing components) to calculate environmental impact for a complete SKF spherical roller bearing 232/530. Dimensions of the bearing: di= 530 mm dy= 980 mm breadth= 355 mm
Process Type	Gate to gate
Site	SKF Sverige AB415 50 GÖTEBORG
Sector	Materials and components
Owner	SKF Sverige AB415 50 GÖTEBORG
Technical system description	This activity describes a process step included in the system ''Production of brass cages used for spherical roller bearings'', also available in the SPINE@CPM database. Turned brass cylinders are bought from BecoTek AS in Norway (see ''Production of turned brass cylinders''). At the SKF plant in Göteborg the brass cylinders are treated and processed in several steps to obtain the desired shape. 1. First the cylinders are turned in the Morando lathe (66 minutes). 2. The cylinders are then drilled. The drilling takes about 93 minutes and is the most time consuming step in the process. 3. To get rid of sharp edges from the drilling, the cages are then ground by hand. 4. The last step is to trumble the cages with trumble chips made of ceramic stones to get a smooth surface. The cages are then transported, by industrial trucks, to the C-factory at SKF where the final assembly takes place. (1 km electric truck transport is included) The trumbling chips are not included in this study, since the amount of chips needed for one cage was insignificant. Also the energy consumption for the trumbling of the cages was neglected since it is very small in comparison to the energy consumption of the other process equipment. The brass-scrap from the SKF process is transported to Västerås, Sweden, for complete recycling. This transport and recycling activity is NOT included in this dataset. The cutting fluid is transported to Halmstad for destruction and use as energy source in the Cement-industry. This transport and destruction activity is NOT included in this dataset. See the activity ''Production of brass cages used for spherical roller bearings'' for futher information.

System Boundaries	
Nature Boundary	No emissions to air are included since they were not known and measured. The trumble chips are not followed from the cradle and not to the grave. The brass scrap that leaves the system is considered to be a co-product since it is used as raw material for new products and thus the boundary is the technosphere. The mineral oil in the cutting fluid has NOT been accounted for. The cutting fluid is an emulsion with water and 4% of CASTROL SW 3420. According to the product data sheet for CASTROL SW 3420 it consists of 40% mineral oil. Databases for ''Extraction of crude oil'' and ''Refining of crude oil'' from SPINE@CPM can be used for tracing the mineral oil to its

	cradle. The activity ''Combustion of waste oil'' can be used for following the mineral oil to its grave. This is also a separate activity that can be found in SPINE@CPM database.
Time Boundary	The data is collected during autumn 2002. No changes in the procedure are planned for the nearest future.
Geographical Boundary	The manufacturing of cages takes place at SKF in Göteborg, Sweden.
Other Boundaries	In the activity ''Manufacturing of brass cages at SKFs site in Göteborg'' also internal transport within SKF industrial area 1 km electric truck is included and the electricity production needed for this (0,75 kWh/km) This assumption of energy consumption is made at BeTe Trucks AB in Sweden. The electricity production is NOT included. Swedish average electricity production should be used.
Allocations	For the process at SKF in Göteborg the data is production specific to the specific cage. For other cages with different dimensions the processing time in the different process equipment can vary, and thus also the energy consumption can vary.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	02-08-01 - 02-12-31
Data Type	Derived, mixed
Represents	See 'Function'
Method	Most of the data is obtained from estimations from the production manager Christer Landgren. The finished brass cage is weighted to obtain the correct weight, 55,6 kg. Other data is descibed for each flow.
Literature Reference	Jonasson K., Environmental Aspects of the Use-Phase for Bearings in Trains. Environmental Systems Analysis, Report 2003:3, ISSN 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://www.cpm.chalmers.se/CPMDatabase/DataReferences/ESA_2003--3.pdf
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

About Inventory	
Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The data is valid for production of brass cages of this dimension at the specific site at SKF in Göteborg, Sweden.
About Data	Data is gathered from meassurements in the cage factory and from interviews with Christer Landgren, SKF Sverige AB.

SPINE LCI dataset: Manufacturing of CD-R (Compact Disc-Recordable). ESA-DBP

Administrative	
Finished	Y
Date Completed	1997
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Manufacturing of CD-R (Compact Disc-Recordable). ESA-DBP
Functional Unit	1 pce of CD-R
Functional Unit Explanation	1 compact disc-recordable.
Process Type	Gate to gate
Site	LOGOS, Göteborg, Sweden
Sector	Manufacturing
Owner	LOGOS, Göteborg, Sweden
Technical system description	Excerpt from the report, see 'Publication': ''CD-R has got a recording layer of cyanide dye between the PC and the reflecting layer and the reflecting layer is made of gold (...). The cyanide dye is sensitive to ultraviolet light. The recording is done by ultraviolet laser which changes the layer to become absorbing instead of transparent. (...) - The manufacturing chain starts with preparing a glass disc with a photo resistant layer. The glass disc is then recorded with a laser. In the CD-R manufacturing only tracks for the laser beam are recorded. The following step is to develop and coat the surface with thin layer of metal.

	- The next step is electroforming, where the developed disc is covered by nickel. The nickel part which is called the metal father and the glass disc are then separated. Once again electroforming is used to produce a negative nickel copy which is called the mother. The metal mother is made as a safety copy from which it is easy to make a second metal father which can be used as a stamper. - The stamper is put in a moulding machine where it is brought in contact with melted polycarbonate under high pressure, it conforms to the stampers contours, producing a substrate disc with pits or tracks. For the CD-R manufacturing an additional step of spin coating the surface of the disc with a very thin recording dye layer is carried out before the next step. - To the moulded disc the reflective layer is applied by magnetron suttering, this layer usually consists of (...) gold. - To protect the thin and sensitive metal layer the disc is spin coated with an acrylic resin. Finally it is common to give the discs a label by screen printing with acrylic resin. The recording area of a CD, between the 46 mm inner and 117 mm outer radius, is 90.85cm2. This area have been used to calculate to amounts of material used in some of the stages. (...) The finished product is blank CD with no stored data, therefore a recording session will follow. (...) When the CD is finished it is put in Jewel box together with a booklet. The weight of a CD library will be less than 200g including transport packaging.'' (NB: excluded from the study) This process is included in the system described in: Beckman T. (1997). Gutenberg versus IT. A Life Cycle Assessment of printed and CD-stored information. Technical Environmental Planning, Report 1997:3, Chalmers University of Technology. Gothenburg, Sweden. Other processes in the CPM Database also included in the above publication: - Manufacturing of CD-ROM (Compact Disc - Read Only Memory). ESA-DBP - Dioctyl phthalate (DOP) production. ESA-DBP - Cultivation and felling of trees for papermaking. ESA-DBP - Cardboard production (MDF based). ESA-DBP - Production of copypaper. ESA-DBP - Production of orthoxylene. ESA-DBP

System Boundaries

Nature Boundary	The inventory analysis included parameters describing resource use (energy and raw materials). Polycarbonate will be reused.
Time Boundary	1996-1997
Geographical Boundary	Sweden
Other Boundaries	The recording session requires a small amount of electricity but no data for this have been available and is therefore omitted in this study. (...) The transport packaging is not inluded in this study. The mastering of the father, stamper will not be included since the same stamper can be used to all discs why it can be considered as a part of the machine and the production of machines are not included in this study. From the manufacturing of one CD, 1.80g polycarbonate is wasted and sent to recycling. Of this recycled PC 40%, (weight), is coated with metal.''

SPINE LCI dataset: Manufacturing of Cold Rolled Steel Tubes, 41,55 x 37,21 or 47,75 x 41,01 mm

Administrative

Finished	Y
Date Completed	2002-08
Copyright	
Availability	Public

Technical System

Name	Manufacturing of Cold Rolled Steel Tubes, 41,55 x 37,21 or 47,75 x 41,01 mm
Functional Unit	1 ton Cold rolled steel tubes, 41,55 x 37,21 or 47,75 x 41,01 mm
Functional Unit Explanation	41,55 x 37,21 means that the outer diameter is 41,55 mm and the inner diameter 37,21 mm. It is the same for 47,75 x 41,01 mm. The steel quality is SKF3 100Cr6.

Process Type	Gate to gate
Site	Cold Rolling Mill Ovako Steel AB 813 82 Hofors Sweden
Sector	Materials and components
Owner	Cold Rolling Mill Ovako Steel AB 813 82 Hofors Sweden
Technical system description	The Colled rolled steel tubes of diameters 41,55 x 37,21 mm and 47,75 x 41,01 mm are manufactured from Hot rolled steel tubes of diameter 70,7 x 47,5 mm. The steel quality is SKF3 100Cr6. The tubes are purchased from the Hot rolling mill at the same manufacturing plant, Ovako Steel AB. The production of Hot rolled steel tubes is not included here, but are presented as a separate data set (see the activity about ''Manufacturing of Hot Rolled Steel Tubes''). Manufacturing processes included in this activity are: 1. Cold rolling 2. Surface treatment: a. Grinding b. Peeling 3. Inspection (ultra sonic) The tubes are processed by cold rolling and then passed on for surface treatment. Depending on customer demand, the surface treatment is either grinding or peeling. The difference between grinding and peeling is mostly cosmetic. The grinding and peeling both result in about the same amount of steel scrap and the scrap is recycled in both cases. After surface treatment the tubes are controlled for cracks with ultra sound (inspection), cut and delivered. Cleaning of process water is not included in the system.

System Boundaries

Nature Boundary	Emissions to air are not included due to lack of data. Emissions to water are considered and the recipient is Hoån, Sweden.
Time Boundary	The data is based on the production in 1998.
Geographical Boundary	The cold rolling mill is located in Hofors, Sweden.
Other Boundaries	Production of refined resources is not included. Refined resources not included: - Hot rolled steel tube - District heating - Emulsion - Hydraulic oil - Steam Production of electricity is not included. Waste treatment is not included. Subsystems concearning employees are not included. Transports are not included. Maintenance of machinery is not included.
Allocations	Allocations have been made according to weight. At the Ovako Steel Cold Rolling Mill, steel tubes can be produced by either cold rolling or cold drawing. Data that corresponds to cold drawing is excluded because the tubes in this activity are produced by cold rolling. The total amount of emissions and waste for production of all cold rolled steel tubes are divided by the total amount of produced tonnes of steel tubes. This gives the amount of emissions and waste that corresponds to the production of 1 ton cold rolled steel tubes.
Systems Expansions	Not relevant

About Inventory

Publication	The data will be published in the Master thesis: ''LCA for the Plain Bearing GE30, Manufactured from Steel Tubes'' by Jesper Nilsson, Göteborgs Universitet/Chalmers University of Technology in 2001. -- Data documented by Jesper Nilsson, MSc thesis worker at SKF. Documentation reviewed by Karolina Flemström, IMI, Chalmers University of Technology Data published in SPINE@CPM 2002-09-09
Intended User	Suppliers and buyers of steel
General Purpose	The general purpose for this data inventory is to document data in a way suitable for LCA studies.
Detailed Purpose	The data will be used in the Master thesis: ''LCA for the Plain Bearing GE30, Manufactured from Steel Tubes'' by Jesper Nilsson, Göteborgs Universitet/Chalmers University of Technology in 2001. The reason for carrying out this LCA was to describe the environmental performances of the SKF plain bearing GE30. The main purpose was to find out which activities during the life cycle of the GE30, that contribute to most negative environmental impacts. GE30 was chosen because there already was some life cycle inventory data available for this bearing type and because it is the most sold bearing at SKF Gleitlager. The plain bearing GE30 is manufactured from cold rolled steel tubes of quality SKF3, 100Cr6. One of the activities included is production of Cold rolled steel tubes.

Reviewer	
Applicability	The data is applicable to the production of Cold rolled steel tubes of steel quality SKF3, 100Cr6 at the Cold Rolling Mill at Ovako Steel in Hofors, Sweden. The data is an average of all tubes manufactured by cold rolling at Ovako Steel. The cold rolled steel tubes have gone through several manufacturing steps at the Ovako Steel factory in Hofors. These steps are all presented as separate data sets, see the activities about: 1. ''Production of bearing steel'' 2. ''Manufacturing of Hot Rolled Round Steel Billets'' 3. ''Manufacturing of Hot Rolled Steel Tubes''
About Data	The data is provided by Rickard Qvarfort at the Cold rolling mill at Ovako Steel AB in Hofors, Sweden. It is not specified if the data is derived, monitored, estimated, from economical information or calculated in some other way. All data was recieved as annual inputs and outputs for the entire Cold rolling mill.

Technical System	
Name	Manufacturing of Hot Rolled Round Steel Billets, 80 mm
Functional Unit	1 ton of Hot rolled round steel billets, 80 mm
Functional Unit Explanation	The steel quality of the round billets of diameter 80 mm is SKF3, 100Cr6.
Process Type	Gate to gate
Site	Rolling Mill Ovako Steel AB 813 82 Hofors Sweden
Sector	Materials and components
Owner	Rolling Mill Ovako Steel AB 813 82 Hofors Sweden
Technical system description	The Hot rolled round steel billets are manufactured from Steel ingots, which are purchased from the Steel mill at Ovako Steel. The production of Steel ingots is not included here, but is presented as a separate data set (see the activity about ''Production of bearing steel''). The steel quality is SKF3, 100Cr6. These process steps are included in the data set: 1. Pit Furnace 2. Billet rolling, stand 1 3. Oxygen scarfing 4. Billet rolling, stand 2 5. Billet rolling, stand 3 6. Partitioning (cutting) 7. Cooling bed 8. Shot blasting 9. Surface treatment if needed after inspection (grinding) When the ingots are put in the pit furnace they have a temperature of about 800 degrees Celsius. Six of the furnaces have oxyfuel technology, six have oil/air combustion and one is heated with liquefied petroleum gas. In the furnace the ingots are heated up to rolling temperature which is about 1200 degrees. When the rolling temperature is reached the ingots are soaked for three hours. The ingots are rolled in 26 passes down to 220 square and are thereafter sent through the

	oxygen scarfing. Added in the oxygen scarfing process are LPG, oxygen, polymers and water. In rolling stand 2 the ingots are rolled down to 150 mm square billets and passed on to rolling stand 3. In rolling stand 3 the rolling of round billets of different diameters take place (80, 90 and 120 mm). These are the final dimensions and the billets are now cut (partitioning) and put on a cooling bed until the temperature is at a maximum of 100 degrees. After that the billets are sand blasted, inspected and surface defects, if any, are removed by grinding. The process steps 1- 4 are called Production line I and process steps 5- 9 are called Production line II.

System Boundaries

Nature Boundary	Emissions to air are included. Emissions to water are not included due to lack of data. The recipient of waste water is Hoån. Residues to the technosphere are not further followed to the grave. Landfilled residues are deposited within Ovako Steel land property, but possible leakage to soil and ground water is not known.
Time Boundary	The data is based on the production of steel billets in 1998.
Geographical Boundary	The Ovako Steel Rolling Mill is located in Hofors, Sweden.
Other Boundaries	Production of refined resources is not included. Refined resources not included: - Steel ingot - Brick - Dolomite - Grease - Hydraulic oil - Light fuel oil - LPG - N2 - O2 - Polymers Production of electricity is not included. Transports are not included, exept for internal transport with electrical industrial truck. Waste treatment is not included. Subsystems concearing employees are not included. Recycling of steel scrap is not included.
Allocations	Allocations have been made according to weight. Specification of weights of the flows for production of billets at the : - Total weight of steel ingots into Production line I; 410 427 tons - Total weight of billets out from Production line II; 156 575 tons - Total weight of billets for tubes out from Production line II; 106 761 tons - Total weight of billets out from Production line III; 183 225 tons For description of Production line I(process step 1-4) and II (process step 4-9) see Function. Production line III is the production of square billets and data for this flow is not included in this data set, except that the weight into Production line III has been taken in consideration in the allocations. Allocations: - The different steel billets produced at Ovako Steel are 80, 90, 120 mm round and 150 mm square. - The manufacturing process is the same until after rolling stand 2, where all billets are 150 mm square. - After that the billets go to partitioning (Production line III) or to further rolling procedures (Production line II). - The total output weight forProduction line II and III is 339 000 tons. Therefor Production line II counts for 46,1% of Production line I. - For the input and output data in Production line II no difference has been made between the different dimensions of round billets. In other words it is assumed that the billets are processed equally regarding time, oil, etc. - Only the weight of the billets has been used as basis for allocation. - The total weight of round billets produced in Production line IIwhere 156 575 tons. Therefor these tubes count for all of the input and output data specific for flow 2. - As an example these billets counts for 46,1 % of electricity consumption in Production line I and all of the electricity consumptin in Production line II.
Systems Expansions	Not relevant

Flow Data

General Activity QMetaData

Date Conceived	1998-01-01 - 2000-02-28
Data Type	Derived, mixed
Represents	Ovako Steel AB in Hofors
Method	The data is based on productin data at the Rolling Mill at Ovako Steel AB in Hofors, Sweden. Emission data is all monitored by authorised companies, except for CO2 emissions that are derived from the carbon content in the combusted fuel.
Literature Reference	Internal information from Ovako Steel as recived from Lars-Gunnar Larsson at the rolling mill at Ovako Steel AB.
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

Flow Table and Specific Meta Data

QMetaData	***Direction***	***FlowType***	***Substance***	***Quantity***	***Min***	***Max***	***Unit***	***Environment***	***Geography***
Data type: Monitored data, continuous Notes: Measured by B. Kvarnström, not specified how.	Input	Natural resource	Municipal water	0.14			m3	Ground	Sweden
Data type: Unspecified, guesstimate Notes: The use of Surface water is estimated by Lars-Gunnar Larsson at the Rolling Mill at Ovako Steel AB in Hofors.	Input	Natural resource	Surface water	2.01			m3	River	Sweden
Data type: Economical information Notes: Purchased weight.	Input	Refined resource	Brick	0.16			kg	Technosphere	Sweden
Data type: Economical information Notes: Purchased weight	Input	Refined resource	Dolomite	0.029			kg	Technosphere	Sweden
Data type: Monitored data, continuous Notes: Not specified by provider from Ovako Steel, Lars-Gunnar Larsson.	Input	Refined resource	Electricity	105			kWh	Technosphere	Sweden
Data type: Economical information Notes: Purchased weight	Input	Refined resource	Grease	0.054			kg	Technosphere	Sweden
Data type: Monitored data, discrete Notes: Measured by Per Hellberg, not specified how.	Input	Refined resource	Hydraulic oil	0.115			l	Technosphere	Sweden
Data type: Monitored data, discrete Method: The consumption of Light fuel oil is measured to 17,96 kg for production of 1 ton Hot rolled round steel billets. The energy content of light fuel oil is 11,6 kWh/kg according to Physics Handbook. The energy content of 17,96 kg light fuel oil therefore is 208 kWh. Literature: Physics handbook, T-8.5, 1996 Notes: Measured by T. Klaussen, not specified how.	Input	Refined resource	Light fuel oil	208			kWh	Technosphere	Sweden
Data type: Monitored data, discrete Method: The consumption of LPG is measured to 3,442 kg for production of 1 ton Hot rolled round steel billets. The energy content of LPG is 12,8 kWh/kg according to Physics Handbook. The energy content of 3,442 kg LPG therefore is 44,1 kWh. Literature: Physics handbook, T-8.5, 1996 Notes: Measured by T. Klaussen, not known how. LPG is Liquefied Petroleum Gas. The gas is a mixture of Propane (C3H8) and Butane (C4H10).	Input	Refined resource	LPG	44.1			kWh	Technosphere	Sweden
Data type: Unspecified Notes: Provider of information T. Klaussen.	Input	Refined resource	N2	0.006			m3	Technosphere	Sweden
Data type: Monitored data, discrete Notes: Measured by T. Klaussen, not known how. The Oxygen gas has a temperature of 15 degrees Celsius.	Input	Refined resource	O2	27.7			m3	Technosphere	Sweden
Data type: Unspecified Notes: The data origin is not known, but provider of information is Stewen Persson at Ovako Steel. Chemical name: 2-propenic acid with 2-polyacrylamide	Input	Refined resource	Polymers	5.15			ml	Technosphere	Sweden
Data type: Economical information Notes: Purchased from the Steel Mill. The temperature is about 800 degrees Celsius.	Input	Refined resource	Steel ingot	1.202			tonne	Technosphere	Sweden

Data type: Derived, unspecified Notes: Data is calculated by H. Burtsoff at Ovako Steel, not known how.	Output	Emission	CO2	43.1			kg	Rural air	Sweden
Data type: Monitored data, discrete Notes: Measured by H. Burtsoff, not known how.	Output	Emission	Dust	25.3			mg	Rural air	Sweden
Data type: Estimated from similarity Notes: Estimated from similarity by H. Burtsoff, not known how.	Output	Emission	NOx	177			g	Rural air	Sweden
Data type: Derived, unspecified Notes: Data is calculated by H. Burtsoff at Ovako Steel, not known how.	Output	Emission	SO2	53			g	Rural air	Sweden
Data type: Unspecified, guesstimate Notes: The output of water is estimated to be the same as the sum of municipal water input and surface water input. The surface water input is estimated by Lars-Gunnar Larsson at the Rolling Mill at Ovako Steel AB in Hofors.	Output	Emission	Waste water	2.15			m3	River	Sweden
	Output	Product	Hot rolled round steel billets	1			tonne	Technosphere	Sweden
Data type: Economical information Notes: This is the purchased amount of bricks for production of 1 ton Hot rolled round steel billets. The brick residue is recycled back to one of the suppliers Fagerst Eldfasta, Bjuv or Höganäs.	Output	Residue	Brick	0.16			kg	Technosphere	Sweden
Data type: Economical information Notes: This is the purchased amount of dolomite for production of 1 ton Hot rolled round steel billets. The dolomite residue is deposited at the landfill within Ovako Steel land property.	Output	Residue	Dolomite	0.029			kg	Landfill ground	Sweden
Data type: Monitored data, discrete Notes: This is dust from shot blasting and grinding. The content is mostly FeO and Fe metal. The dust residue is deposited at the landfill within Ovako Steel land property.	Output	Residue	Dust	4.74			kg	Landfill ground	Sweden
Data type: Economical information Notes: This is the purchased amount of grease for production of 1 ton Hot rolled round steel billets. The grease residue is sent to a waste treatment company for destruction.	Output	Residue	Grease	0.054			kg	Technosphere	Sweden
Data type: Unspecified Notes: The hydraulic oil residue is assumed to be the same amount as the hydraulic oil input. It is sent to a waste treatment company for destruction.	Output	Residue	Hydraulic oil	0.115			l	Technosphere	Sweden
Data type: Monitored data, discrete Notes: The slag is granulate from the oxygen scarfing process. The slag residue is deposited at the landfill within Ovako Steel land property. The content of the slag (by weight-%): SiO2 0,04 MnO 0,034 P2O5 0,007 Cr2O3 1,02 NiO 0,13 MgO 0,02 CuO 0,27 V2O5 0,012 TiO2 0,004 Al2O3 0,02 FeO 75,2 CaO 0,01 Na2O 0,002 K2O 0,004 ZnO 0,01 PbO 0,003 C 0,31 S 0,009 Fe met. 23 (Iron as metal) Moist. 7,9 (Water)	Output	Residue	Slag	30.9			kg	Landfill ground	Sweden
Data type: Monitored data, discrete Notes: The sludge is from the oxygen scarfing process. The slag residue is deposited at the landfill within Ovako Steel land property. The content of the slag (by weight-%): SiO2 0,04 MnO 0,31 P2O5 0,01 Cr2O3 0,77 NiO 0,125 MgO 0,02 CuO 0,29 V2O5 0,012 TiO2 0,01 Al2O3 0,04 FeO 89,0 CaO 0,02 Na2O 0,005 K2O 0,008 ZnO 0,02 PbO 0,01 C 0,12 S 0,009 Fe met. 2,0 (Iron metal) Moist. 28,6 (Water)	Output	Residue	Sludge	9.06			kg	Landfill ground	Sweden
Data type: Monitored data, discrete Notes: The steel scrap is losses in the pit furnace, cutting, partitioning and other processes. The scrap is recycled back to the scrap yard at Ovako Steel.	Output	Residue	Steel scrap	144			kg	Technosphere	Sweden

About Inventory	
Publication	The data will be published in the Master thesis: ''LCA for the Plain Bearing GE30, Manufactured from Steel Tubes'' by Jesper Nilsson, Göteborgs Universitet/Chalmers University of Technology in 2001. -- Data documented by Jesper Nilsson, MSc thesis worker at SKF. Documentation reviewed by Karolina Flemström, IMI, Chalmers University of Technology Data published in SPINE@CPM 2002-09-09
Intended User	Suppliers and buyers of steel
General Purpose	The general purpose for this data inventory is to document data in a way suitable for LCA studies.
Detailed Purpose	The data will be used in the Master thesis: ''LCA for the Plain Bearing GE30, Manufactured from Steel Tubes'' by Jesper Nilsson, Göteborgs Universitet/Chalmers University of Technology in 2001. The reason for carrying out this LCA was to describe the environmental performances of the SKF plain bearing GE30. The main purpose was to find out which activities during the life cycle of the GE30, that contribute to most negative environmental impacts. GE30 was chosen because there already was some life cycle inventory data available for this bearing type and because it is the most sold bearing at SKF Gleitlager. The plain bearing GE30 is manufactured from cold rolled steel tubes of quality SKF3, 100Cr6. One of the activities included is production of Hot rolled round steel billets.
Commissioner	SKF Nova - Chalmers Teknikpark 412 88 Göteborg Sweden .
Practitioner	Jesper Nilsson - Nybohovsbacken 31, 4 tr 121 63 Stockholm Sweden .
Reviewer	
Applicability	The data is applicable to the production of Hot rolled round steel billets of steel quality SKF3 100Cr6 at the Rolling Mill at Ovako Steel in Hofors, Sweden. It is applicable to billets of diameter 80mm. However,since allocations have been made according to weight, the data can probably also be applicable to other Hot rolled steel tubes manufactured from 80mm Hot rolled round steel billets. The Hot rolled round steel billets are produced from steel ingots. This manufacturing step is presented as a separate data sets, see the activities about ''Production of bearing steel''.
About Data	The data is based on production data, economical information, monitoring and estimations at the Rolling Mill at Ovako Steel AB in Hofors, Sweden. All data was recieved as annual inputs and outputs for the entire Hot rolling mill.
Notes	

SPINE LCI dataset: Manufacturing of Hot Rolled Square Billets, 150 mm

Finished	Y
Date Completed	2000-01-14
Copyright	
Availability	Public

Technical System	
Name	Manufacturing of Hot Rolled Square Billets, 150 mm
Functional Unit	One ton of hot rolled square billet, 150 mm.
Functional Unit Explanation	
Process Type	Gate to gate
Site	Rolling Mill Ovako Steel AB 813 82 Hofors Sweden
Sector	Materials and components

Owner	Rolling Mill Ovako Steel AB 813 82 Hofors Sweden
Technical system description	The following process steps are included in the data set: 1. Pit Furnace 2. Billet rolling, stand 1 3. Oxygen scarfing 4. Billet rolling, stand 2 5. Partitioning 6. Cooling bed The raw material is ingots from the Steel mill. When the ingots are put in the pit furnace they have a temperature of about 800 degrees Celsius. 6 of the furnaces have oxyfuel technology, 6 have oil/air combustion, 1 is heated with liquefied petroleum gas. In the furnace the ingots are heated till rolling temperature which is about 1200 degrees. When the rolling temperature is reached the ingots are soaked for three hours. The ingots are rolled in 26 passes down to 220 square and are thereafter sent through the oxygen scarfing. In rolling stand 2 the ingots are rolled down to 150 mm square billets. This is the final dimension and the billets are now cut and allowed to cool in the cooling bed till maximum 100 degrees.

System Boundaries

Nature Boundary	Emission to air and water are included. These are the main emissions and they are reported to the authorities in the annual environmental report. Emissions to soil are not known and not reported to the authorities. The water recipient is Hoån.
Time Boundary	The data are based on the production in the year 1998. In the beginning of the year 2000 the dimension of the billets produced will change from 150 mm square to 145 mm square.
Geographical Boundary	The Ovako Steel rolling mill is located in Hofors, Sweden.
Other Boundaries	Production of the raw material is not included. Production of electricity is not included. Transports are not included, exept for internal transport with electrical industrial truck. Waste treatment is not included. Subsystems concearing employees are not included. Recycling of steel scrap is not included.
Allocations	First the level of detail in the system has been increased to separate the process routes. For processes where it was not possible to separate how specific types of steel influence the process, the data have been divided by the tons produced in that specific process.
Systems Expansions	not relevant

Flow Data

General Activity QMetaData

Date Conceived	1998-01-01

SPINE LCI dataset: Manufacturing of Hot Rolled Steel Tubes, 70,7 x 47,5 mm

Administrative	
Finished	Y
Date Completed	2002-08
Copyright	
Availability	Public

Technical System	
Name	Manufacturing of Hot Rolled Steel Tubes, 70,7 x 47,5 mm
Functional Unit	1 ton of Hot rolled steel tubes, 70,7 x 47,5 mm
Functional Unit Explanation	The bearing steel quality is SKF3, 100Cr6. 70,7 mm is the outer diameter and 47,5 the inner diameter of the tube.
Process Type	Gate to gate
Site	Tube Mill 5 Ovako Steel AB 813 82 Hofors Sweden
Sector	Materials and components
Owner	Tube Mill 5 Ovako Steel AB 813 82 Hofors Sweden
Technical system description	The hot rolled steel tubes of diameter 70,7 x 47,5 mm are manufactured from 80 mm Hot rolled round steel billets. They are purchased from the Rolling mill at Ovako Steel and the billets are cold when they get to the Tube mill. The production of Hot rolled round steel billets is not included here, but is presented as a separate data set (see the activity about ''Manufacturing of Hot Rolled Round Steel Billets''). The steel quality is SKF3, 100Cr6. Manufacturing processes for this activity: 1. Heating in the Rotary hearth furnace 2. Centering 3. Piercing 4. Assel mill 5. Reducing mill 6. Calibrating and straightening mill 7. Cooling bed In a rotary furnace the billets are heated to rolling temperature, about 1 200°C. The centre is marked in one of the end surfaces of the billet, the billet is forced over a plug and the hole is pierced. The wall thickness of the tube is decided by rolling over a mandrel in the Assel mill. In the reducing mill, the outer diameter of the tube is determined. The next step is the calibrating and straightening mill, where the dimensions of the tube are finely adjusted. After that the tube is placed on a cooling bed. The hot rolled tubes are then directly transported to the customer or passed on for further processing. The transport is not included in this data set.

System Boundaries	
Nature Boundary	Emissions to air are considered. Emissions to soil are not known. Emissions to water are not included due to lack of data. The recipient of waste water is Hoån.

Time Boundary	The data is based on the production in 1998.
Geographical Boundary	The Tube mill is located in Hofors, Sweden.
Other Boundaries	Production of refined resources is not included. Refined resources not included: - Hot rolled round steel billets - District heating - Emulsion - Hydraulic oil - LPG Production of electricity is not included. Waste treatment is not included. Subsystems concearning employees are not included. Transports are not included. Maintenance of machinery is not included.
Allocations	Allocations have been made according to weight. The input and output data for production of all hot rolled steel tubes is divided by the total amount of produced tonnes of hot rolled steel tubes (46927 ton). This gives the amount of emissions and waste that corresponds to the production of 1 ton hot rolled steel tubes.
Systems Expansions	Not relevant

Data type: Monitored data, discrete	Input	Refined resource	Hot rolled round steel billets	1.069			tonne	Technosphere	Sweden
Data type: Derived, unspecified Notes: Data calculated by Cecilia Persson at the hot tube mill, not known how.	Input	Refined resource	Hydraulic oil	0.25			l	Technosphere	Sweden
Data type: Monitored data, discrete Method: The consumption of LPG is measured to 48,6 kg for production of 1 ton Hot rolled round steel billets. The energy content of LPG is 12,8 kWh/kg according to Physics Handbook. The energy content of 48,6 kg LPG therefore is 621 kWh. Literature: Physics handbook, T-8.5, 1996 Notes: LPG is Liquefied Petroleum Gas. The gas is a mixture of Propane (C3H8) and Butane (C4H10).	Input	Refined resource	LPG	621			kWh	Technosphere	Sweden

Data type: Derived, unspecified Notes: Data calculated by Cecilia Persson at the hot tube mill, not known how.	Input	Refined resource	Municipal water	0.104			m3	Technosphere	Sweden
Data type: Estimated from similarity Notes: Furnace 38 gives an emission of 20 mg CO/MJ LPG combusted. Provider of information is Cecilia Persson at the hot rolling mill.	Output	Emission	CO	0.045			kg	Rural air	Sweden
Data type: Estimated from similarity Notes: Calculated according to the carbon content in the combusted LPG.	Output	Emission	CO2	73.6			kg	Rural air	Sweden
Data type: Estimated from similarity Method: Furnace 38 gives an emission of 50 mg NOx/MJ LPG combusted. Provider of information is Cecilia Persson at the hot rolling mill.	Output	Emission	NOx	0.112			kg	Rural air	Sweden
Data type: Unspecified Notes: Provided by Cecilia Persson at the hot rolling mill.	Output	Emission	Waste water	4.33			kg	River	Sweden
Data type: Monitored data, discrete	Output	Product	Hot rolled steel tube	1			tonne	Technosphere	Sweden
Data type: Derived, unspecified Notes: Data calculated by Cecilia Persson at the hot tube mill, not known how. The emulsion residue is sent to a waste treatment company for destruction.	Output	Residue	Emulsion	3.9			kg	Technosphere	Sweden
Data type: Derived, unspecified Notes: Data calculated by Cecilia Persson at the hot tube mill, not known how. The oil residue is sent to a waste treatment company for destruction.	Output	Residue	Oil	0.3			kg	Technosphere	Sweden
Data type: Derived, unspecified Notes: Data calculated by Cecilia Persson at the hot tube mill, not known how. The slag residue is deposited at the landfill within the Ovako Steel land property.	Output	Residue	Slag	22.7			kg	Technosphere	Sweden
Data type: Derived, unspecified Notes: Data calculated by Cecilia Persson at the hot tube mill, not known how. The steel scrap is recycled back to the scrap yard at Ovako Steel.	Output	Residue	Steel scrap	53			kg	Technosphere	Sweden

About Inventory	
Publication	The data will be published in the Master thesis: ''LCA for the Plain Bearing GE30, Manufactured from Steel Tubes'' by Jesper Nilsson, Göteborgs Universitet/Chalmers University of Technology in 2001. --- Data documented by Jesper Nilsson, MSc thesis worker at SKF. Documentation reviewed by Karolina Flemström, IMI, Chalmers University of Technology Data published in SPINE@CPM 2002-09-09
Intended User	Suppliers and buyers of steel
General Purpose	The general purpose for this data inventory is to document data in a way suitable for LCA studies.
Detailed Purpose	The data will be used in the Master thesis: ''LCA for the Plain Bearing GE30, Manufactured from Steel Tubes'' by Jesper Nilsson, Göteborgs Universitet/Chalmers University of Technology in 2001. The reason for carrying out this LCA was to describe the environmental performances of the SKF plain bearing GE30. The main purpose was to find out which activities during the life cycle of the GE30, that contribute to most negative environmental impacts. GE30 was chosen because there already was some life cycle inventory data available for this bearing type and because it is the most sold bearing at SKF Gleitlager. The plain bearing GE30 is manufactured from cold rolled steel tubes of quality SKF3, 100Cr6. One of the activities included is production of Hot rolled steel tubes.
Commissioner	SKF Nova - Chalmers Teknikpark 412 88 Göteborg Sweden .
Practitioner	Jesper Nilsson - Nybohovsbacken 31, 4 tr 121 63 Stockholm Sweden .
Reviewer	

Applicability	The data is applicable to the production of Hot rolled steel tubes of steel quality SKF3 100Cr6 at the Tube Mill at Ovako Steel in Hofors, Sweden. It is applicable to tubes of outer and inner diameters of 70,7 and 47,5 mm respectively. However, since allocations have been made according to weight, the data can probably also be applicable to other Hot rolled steel tubes manufactured from 80 mm Hot rolled round steel billets. This presumes that the tubes go through the same manufacturing processes, see Function for manufacturing processes for this activity. The hot rolled steel tubes have gone through several manufacturing steps at the Ovako Steel factory in Hofors. These steps are all presented as separate data sets, see the activities about: 1. ''Production of bearing steel'' 2. ''Manufacturing of Hot Rolled Round Steel Billets''
About Data	The data is derived, monitord and estimated by Cecilia Persson at Tube mill 5 at Ovako Steel AB in Hofors, Sweden. All data was recieved as annual inputs and outputs for the entire Hot rolling mill.
Notes	

SPINE LCI dataset: Manufacturing of plywood boxes at Nefab in Alfta

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Manufacturing of plywood boxes at Nefab in Alfta
Functional Unit	1 kg plywood box
Functional Unit Explanation	1 kg of the plywood box: NEFAB ExPak type-S, 1160 x 1160 x H). The whole plywood box weighs 52,61 kg. Thus all data must be multiplied with 52,61 in order to obtain the total environmental impact for one whole box.
Process Type	Gate to gate
Site	Nefab Emballage ABNordgrens väg 5 822 92 ALFTA SWEDEN
Sector	Construction
Owner	Nefab Emballage ABNordgrens väg 5 822 92 ALFTA SWEDEN
Technical system description	This activity describes a process step included in the system ''Production of plywood boxes'' , also available in the SPINE@CPM database. Plywood boxes are used to pack the coated and non-coated roller bearings from SKF, Göteborg, during the transportation to customers. The plywood boxes are manufactured by Nefab Emballage AB in Alfta, Sweden. The plywood boxes consist of plywood, steel strips, steel nails and wooden splits. The plywood boxes consist of the following parts: Contents per box Weight (kg) % of total weight Plywood 33.9 64.44 Wooden splits 14.9 28.32 Steel strips 3.7 7.03 Steel nails 0.108 0.21 Manufacturing of plywood boxes at Nefab in Alfta: At Nefab Emballage AB in Alfta the plywood box is mounted, from its ingoing parts: Plywood, Steel strips, Wooden splits and steel nails. The used data refers to an EPD from Nefab Emballage AB for the product NEFAB Expak [Environmental Product Declaration from NEFAB Emballage AB; Doc.no.5-073-103.]. The environmental profile includes emissions from local energy use and internal transportation. The presumed product in the EPD contains plywood (87%) and steel strip (13%).

	The boxes that are used by SKF contains Plywood (1877,6 g ~ 71,01%) and Steelstrip (766,5 g ~ 28,99%).

System Boundaries

Nature Boundary	Emissions to air and water are included. The inputs: plywood, steel nails, steel strips and wooden splits are considered non-elementary from the technosphere, but these inflows should be followed from the cradle with activities from the SPINE@CPM database: * Production of plywood * Virgin steel production * Hot rolling of steel sheet * Pickled hot rolled steel sheet * Cold reducing of steel sheets * Metal coating ofcold reduced steel sheets * Production of wood See more detailed information in the activity ''Production of plywood boxes''
Time Boundary	The dataset is based on an EPD made at Nefab Emballage AB during the year 1997.
Geographical Boundary	The process takes place at Nefab Emballage AB in Alfta, Sweden.
Other Boundaries	The production of electricity, diesel and oil is NOT included in this dataset but must be followed from the cradle in order to calculate the total environmental impact from this activity.
Allocations	Allocations are made according to weight.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	02-08-01 - 02-12-31
Data Type	Derived, mixed
Represents	Ovako Steel AB in Hofors
Method	The used data refers to an EPD from Nefab Emballage AB for the product NEFAB Expak [Environmental Product Declaration from NEFAB Emballage AB; Doc.no.5-073-103.]. The environmental profile includes emissions from local energy use and internal transportation. The presumed product in the EPD contains plywood (87%) and steel strip (13%). The data is recalculated to be valid for the specific product Nefab ExPak type-S, 1160 x 1160 x H, which also includes steel nails and wooden splits. The plywood box consists of the following parts: Contents per box Weight (kg) % of total weight Plywood 33.9 64.44 Wooden splits 14.9 28.32 Steel strips 3.7 7.03 Steel nails 0.108 0.21 The data from NEFAB was for plywood and steel strip = 100 %. In this specific box the plywood and steel strips = 71.47 %, thus the values from the EPD is multiplied with 0.7147.
Literature Reference	Environmental Product Declaration from NEFAB Emballage AB; Doc.no.5-073-103.
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

About Inventory	
Publication	Master thesis: LCA based solution selection; Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. Both types of bearings are packed in a plywood box. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The data is valid for the manufacturing of the plywood box: Nefab ExPak type-S, 1160 x 1160 x H, at Nefab Emballage AB in Alfta, Sweden. The plywood box consists of the following parts: Contents per box Weight (kg) % of total weight Plywood 33.9 64.44 Wooden splits 14.9 28.32 Steel strips 3.7 7.03 Steel nails 0.108 0.21 Note that the production of steel, plywood and wood is not taken into account in this activity. The total impact for producing one plywood box of this type can be seen in the activity ''Production of plywood boxes'' in the SPINE@CPM database.
About Data	The used data refers to an EPD from Nefab Emballage AB for the product NEFAB Expak [Environmental Product Declaration from NEFAB Emballage AB; Doc.no.5-073-103.]. The environmental profile includes emissions from local energy use and internal transportation. The presumed product in the EPD contains plywood (87%) and steel strip (13%). The data is recalculated to be valid for the specific product Nefab ExPak type-S, 1160 x 1160 x H, which also includes steel nails and wooden splits.

SPINE LCI dataset: Manufacturing of polyurethane insulation

Administrative	
Finished	Y
Date Completed	1996-03-01

Copyright	
Availability	Public

Technical System

Name	Manufacturing of polyurethane insulation
Functional Unit	pcs
Functional Unit Explanation	1 pcs of insulation. In the production 47,8% of the insulation pieces are shaped as blocks and 52,2% as pipes. The annual production of 1995 was 132 pcs of insulation blocks and 144 pcs of culvert pipes.
Process Type	Gate to gate
Site	Puritanus Teknik AB Box 2070 433 02 Partille Sweden
Sector	Materials and components
Owner	Puritanus Teknik AB Box 2070 433 02 Partille Sweden
Technical system description	The company manufactures polyurethane insulation. The insulation is shaped as blocks or pipes. One dosage machine is used, PUR Hennecke HK 135. The casting is done in secluded units where the material is injected from the mixing head to the unit through a hole, which is sealed after the filling is done.

System Boundaries

Nature Boundary	The company is not obligated to state other emission- or waste substances than the Swedish Environmental Protection law requires.
Time Boundary	The company is obligated to write an Environmental report once every year. Though the legislated limits can be changed only if the activity is changed.
Geographical Boundary	Sweden
Other Boundaries	
Allocations	
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1995
Data Type	Unspecified
Represents	Ovako Steel AB in Hofors
Method	Studing the Environmental report from Puritanus Teknik AB for 1995 The data in the table has been converted into amounts per functional unit. The data from the environmental report has therefore been devided by the annual production for 1995, which was 132 pcs of insulation blocks and 144 pcs of culvert pipes, which totals to 276 insulation pieces.
Literature Reference	Environmental Product Declaration from NEFAB Emballage AB; Doc.no.5-073-103.
Notes	The data type unspecified implies that one does not know the origin of the data. The enterprise is new and the production is quite low, compared to their limit (400 ton insulation components of polyurethane), but they have plans to expand it further. Then it might be relevant to check up on the emission of MDA and hydrocarbons as well.

Flow Table and Specific Meta Data

QMetaData	***Direction***	***FlowType***	***Substance***	***Quantity***	***Min***	***Max***	***Unit***	***Environment***	***Geography***
	Input	Refined resource	Fuel oil	0.0543			m3	Technosphere	
	Input	Refined resource	Isocyanate	1.88			kg	Technosphere	
	Input	Refined resource	Polyol	1.45			kg	Technosphere	

Date concieved: 1995 Method: The mehtod is to measure the absorbtion of MD1 (isocyanate) in a absorption solvent, which is analysed at a laboratory (KM Miljöteknik AB, Box 331, 401 25 Göteborg, Sweden, Phone: +46 -31 7714900, Fax: +46 -31 802857). An air flow is led through the solvent where the contamination is absorbed. After analyse, the content is multiplied with the amount of air that has passed through the absorption solvent.	Output	Emission	Isocyanate	1.88			mg	Air	
Notes: Consists of polyurethane insulation, disposed by Ragnsell	Output	Residue	Industrial waste	0.109			kg	Technosphere	

About Inventory	
Publication	The Environmental report from Puritanus Teknik AB for 1995, The Board of County in Göteborg and Bohus -- Data documented by: Maria Erixson and Sara Ågren, project employed for the database projet at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	To show the environmental load
General Purpose	The purpose of the Environmental report is to be the base for permission trial of activities that is harmful to the environment and further to make shore that the company comply with the decision.
Detailed Purpose	To control that the legislated limits are not exceeded.
Commissioner	- The Environmental Administration in the municipality of Göteborg Box 360 401 25 Göteborg Sweden.
Practitioner	Söderberg, Ramon VD - Puritanus Teknik AB Box 2070 433 02 Partille Sweden.
Reviewer	- The Environmental Administration in the municipality of Göteborg Box 360 401 25 Göteborg Sweden
Applicability	The function of the technical system is not sufficently described. Contact the company to get the necessary details. The enterprise is new and the production is quite low, compared to their limit (400 ton insulation components of polyurethane), but they have plans to expand it further. Then it might be relevant to check up on the emission of MDA and hydrocarbons as well.

SPINE LCI dataset: Manufacturing of SKF’s Spherical Roller Bearing

Administrative	
Finished	Y
Date Completed	2000-01-18
Copyright	
Availability	Public

Technical System	
Name	Manufacturing of SKF’s Spherical Roller Bearing
Functional Unit	One spherical roller bearing 24024
Functional Unit Explanation	The SRB 24024 is manufactured in production line 4 at the D-factory. It weights 5,40 kg and consists of one outer ring, one inner ring, one guide ring, two cages and 52 rollers.

Process Type	Gate to gate
Site	D-Factory SKF Sverige AB 415 50 Göteborg Sweden
Sector	Consumer goods
Owner	D-Factory SKF Sverige AB 415 50 Göteborg Sweden
Technical system description	The following process steps are included in the data set: 1. Turning 2. Polishing 3. Assembly 4. Rust treatment 5. Packing Besides the above electrified trucks used for internal transports are included. At the SKF D-factory in Göteborg the inner and outer rings are turned, polished and put together with the guide ring, the two cages and the 52 rollers to produce a spherical roller bearing, 24024. The complete bearing is treated with rust preservatives and packed in flow film and a corrugated board box.

System Boundaries

Nature Boundary	Emissions to air and water are not included due to that the emissions that are regarded to be negligeble.
Time Boundary	Most of the data are taken from a waste inventory made in 1997 and based on data for 1996.
Geographical Boundary	The plant is located in Göteborg, Sweden.
Other Boundaries	Transport are not considered except for internal transports carried out by electrical industrial trucks. Subsystems concearning emplyees are not included.
Allocations	The data are allocated according to a distribution key wich is used at SKF to distribute the economic responsibility for waste treatment etc. According to the key SRB Medium stands for 70% of the wastes and the production line 4 stands for 11.62% of these 70 % at the SKF D-factory
Systems Expansions	not relevant

Flow Data

Owner	SKF Gleitlager GmbH Postfach 3020 663 40 Püttlingen GERMANY
Technical system description	The plain bearing GE30 is composed by one inner and one outer ring. The inner and outer rings are manufactured from Cold rolled round steel tubes with outer diameters of 41,55 and 47,75 mm and inner diameters of 37,2 and 41 mm respectively. The tubes are purchased from Ovako Steel AB in Hofors, Sweden and transported to Püttlingen by heavy truck and ferry. Neither the transports or the production of the tubes are included here. The production of the tubes is presented as a separate data set (see the activity about ''Manufacturing of Cold Rolled Steel Tubes''). These process steps are included in the data set: 1. Turning 2. Drilling 3. Washing 4. Heat treatment 5. Grinding 6. Manganese phosphating 7. Assembly 8. Preparation 9. Sealing 10. Inspection 11. Packaging 1. In the turning process a lot of neat cutting oil (ECOCUT 3032 LE) is applied on the tube surfaces continuously. Not all of the oil is collected properly, some of it ends up on the plant floor. The plant floor is therefor once a week filled with wood chips, which absorb the cutting oil The wood chips are collected and sent to a district heating plant for combustion. The collected cutting oil goes together with the turning chips to an oil separator. In the oil separator the turning chips are separated from the cutting oil in three different mechanical filters. The cutting oil is used again for turning and the turning chips are recycled by a steel scrap recycling company. Some of the oil also follows the exhaust gases into the fan system. In the fan system the off gases first are cleaned with condensing and then with an electrostatic filter.

	2. The next step in the production process is drilling and deepering. The reason for the drilling is that two lubrication holes are needed in the GE30 for bearing maintenance during the use. The bearings are lubricated during its use to reduce friction between the bearing surfaces and to extend the bearing lifetime. The deepening of the surface of the inner ring is for keeping the lubrication oil between the outer and inner ring. The drilling chips are collected and transported to the steel briquetting industry together with the turning chips and the grinding sludge. During the drilling a coolant (ECOCOOL SCIP) is added for the process. After separation from the drilling chips, the coolant is recycled and used again. This activity is not quantified for the study. 3. After drilling the rings pass on to the washing, water and chemicals are added into the washing tank. The outputs of this activity are mist extraction, water emissions and oil waste. The water goes to the distillation plant and after the plant the concentrate will be waste oil and the distillate will mostly be water, which is used in the surface treatment (phosphating). The oil waste goes to oil separation and is then used again. 4. In the first step of the heat treatment the rings are heated up to about 180ºC by combustion of natural gas. Then the rings are put in an oil bath for cooling; that is the hardening. The temperature of the quench oil (Isorapid 277 E) in the bath has to be held at about 70 ºC continuously. Therefor the oil bath is connected to an oil tank with thermostat and cooling system and the quench oil is then circulated between the bath and the tank. At the bottom of the oil tank sludge is formed, which is removed two times a year. The sludge is transported to a power plant for combustion. To remove the quench oil from the rings they are washed with water. But in order to prevent the rings from corrosion an anticorrit (P3-neutracare ®400) has to be added to the washing water. The used washing water goes to a vacuum vaporizator where the water is separated from the oil. For description of how the vacuum vaporizator works and where the wastewater and waste oil go see ''Cleaning systems and recycling''. After the washing the rings are dried with Nitrogen gas at a temperature of 140-150 ºC, before they are cooled down with air. At all process steps the exhaust gases are led out through the roof without any cleaning. 5. Grinding stones are used together with a coolant, consistent of 95% water and 5% of the mineral oil Ecocool 1700 S. The grinding waste is dewatered in a press and then the grinding sludge is transported to the metal briquetting industry together with the turning and drilling waste. The water is transported to the central water tank. 6. In order for the plain bearings to maintain the same properties until they are put in use their surfaces have to be protected. Therefor they are manganese phosphated in a multiple process, where a lot of chemicals are involved and therefor the environmental load is clearly significant. The process gives air and water emissions as well as waste sludge and wastewater. 7. The next step is the assembly, where the outer ring is split and the inner ring is pressed into the outer. 8. Preparation: Some of the bearings are Molycote plated at the outer rings inner surface and others are applied with rubbing in oil. This activity is not quantified for the study. 9 & 10. The bearings are sealed and inspected before sent to packaging. 8. The last step is the packaging and the packaging procedures for the GE30 are as follows: - 50% in single pack (54x24x54 mm). - 35% in cassettes with 60 bearings in each (269x182x84 mm). - 15% in bulks with 10 parts in each (115x115x52 mm). The single packaged bearings are first put in a plastic bag and then in a paper box. The bearing type and brand is printed on the box with thermotransfer printer foil. The cassettes are recycled and the bulks are plastics. This means that the packaging of each plain bearing in average requires half of a single pack box and 1,5% of a bulk. After packaging all plain bearings are sent to Schweinfurt and then straight to customers or to Brussels, where they keep stocks of bearings. This activity is not quantified for the study because it is considered to be of very little environmental significance to the result.

System Boundaries	
Nature Boundary	Emissions to air are considered. Emissions to soil are not included due to lack of data. Emissions to water are not included due to lack of data. The waste water is sent to the communal wastewater treatment plant.
Time Boundary	The data is based on the production in 1998.
Geographical Boundary	The production plant is located in Püttlingen, Germany.
Other Boundaries	Production of refined resources is not included. Refined resources not included not included: - Cold rolled steel tube - H_2SO_4 - HCl - Light fuel oil - N_2 - $NaHSO_3$

	- NaOH - Natural gas - Wood chips - Cutting oil - Quench oil Production of electricity is not included. Waste treatment is not included. Subsystems concearning employees are not included. Transports are not included.
Allocations	Energy and water consumption for the entire SKF Gleitlagerplant are representative for the production of plain bearings, rod ends and bushings. It has not been possible to separate the data for the three different products. For allocation of this data the turnover has been used as base. Production of all plain bearings stand for 75 % of the total turnover and it is assumed that they stand for 75 % of this energy and water consumption. The data that is specific for plain bearing production has been allocated by input weight of all the steel tubes used for plain bearing production. 1998 the total input weight of tubes for plain bearing production was 1 943 182 kg. The total weight of tubes for production of GE30:s was 65 802 kg which corresponds to 3,39 %.
Systems Expansions	Not relevant

Flow Data

General Activity QMetaData

Date Conceived	1998-01-01 - 2000-02-28
Data Type	Derived, mixed
Represents	SKF Gleitlager in Püttlingen, Germany
Method	The data is based on production data at the production plant at SKF Gleitlager in Püttlingen, Germany. Emission data is all monitored by authorised companies, except for CO2 emissions that are derived from the carbon content in the combusted fuel.
Literature Reference	SKF Gleitlager internal information as recived from Peter Spengler at SKF Gleitlager in Püttlingen, Germany.
Notes	The data are partly from 1996 and partly from 1998.

About Inventory	
Publication	The data will be published in the Master thesis: ''LCA for the Plain Bearing GE30, Manufactured from Steel Tubes'' by Jesper Nilsson, Göteborgs Universitet/Chalmers University of Technology in 2001. -- Data documented by Jesper Nilsson, MSc thesis worker at SKF. Documentation reviewed by Karolina Flemström, IMI, Chalmers University of Technology Data published in SPINE@CPM 2002-09-09
Intended User	Suppliers and buyers of the SK
General Purpose	The general purpose for this data inventory is to document data in a way suitable for LCA studies.
Detailed Purpose	The data will be used in the Master thesis: ''LCA for the Plain Bearing GE30, Manufactured from Steel Tubes'' by Jesper Nilsson, Göteborgs Universitet/Chalmers University of Technology in 2001. The plain bearing GE30 is manufactured from cold rolled steel tubes of quality SKF3, 100Cr6. The reason for carrying out this LCA was to describe the environmental performances of the SKF plain bearing GE30. The main purpose was to find out which activities during the life cycle of the GE30, that contribute to most negative environmental impacts. GE30 was chosen because there already was some life cycle inventory data available for this bearing type and because it is the most sold bearing at SKF Gleitlager.

Practitioner	Jesper Nilsson - Nybohovsbacken 31, 4 tr 121 63 Stockholm Sweden .
Reviewer	
Applicability	The data is applicable to the production of the plain bearing GE30 at SKF Gleitlager in Püttlingen, Germany. The bearings are manufactured from Cold rolled steel tubes. In 1999 SKF Gleitlager purchased the cold rolled steel tubes from Ovako Steel AB in Hofors, Sweden. The steel quality of the tubes were SKF3, 100Cr6. However, steel tubes from other manufacturers and different steel quality have been used before and might be used in the future. The production process of the plain bearing GE30 at SKF Gleitlager is about the same regardless of the steel tube manufacturer. Therefore the data is not only applicable to production of plain bearings from cold rolled steel tubes manufactured from Ovako Steel, but also to production of plain bearings from steel tubes from other manufacturers. The cold rolled steel tubes from Ovako Steel have gone through several manufacturing steps at the Ovako Steel factory in Hofors. These steps are all presented as separate data sets, see the activities about: 1. ''Production of bearing steel'' 2. ''Manufacturing of Hot Rolled Round Steel Billets'' 3. ''Manufacturing of Hot Rolled Steel Tubes'' 4. ''Manufacturing of Cold Rolled Steel Tubes''
About Data	The data is based on production data at the production plant at SKF Gleitlager in Püttlingen, Germany. Provider was Peter Spengler at SKF Gleitlager. For most of the data it is not specified if the data is derived, monitored, estimated, from economical information or calculated in some other way. When some of these methods have been used, there will be a note about that in specific QMetaData. The data was recieved as annual inputs and outputs. Three different types of the plain bearing GE30 is manufactured at SKF Gleitlager. The inner diameter of all types are 30 mm. However the width of the outer ring differs between 18-22 mm and the inner ring between 22-30 mm. The mass of all types of the plain bearing GE30 is 0,16 kg per piece, except for a small amount of bearings that are of mass 0,17 kg per piece. This small amount effects the total very little and all plain bearings are therefor assumed to be of mass 0,16 kg per piece.

Technical system description	Theoretical model for manufacturing of polyurethane. MDI and PTMG are forming a prepolymere and solving in a solvent dimethyleacetamide (DMAC) and cured with 4,4'-diphenylmethanediamine (DMDA). n(HO(R1)OH) + n(OCN(R2)NCO) = H(O(R1)OCONH(R2)NHCO)nOH R1=(CH2)4O R2=C6H4CH2C6H4 MDI can be substituted by TDI, but this substance is more toxic. Other chain extenders than DMDA could be used, but this one is assumed to be close enough for this model.

Method	A supplier recipe stated the amounts of MDI and PTMG. Out of this the amounts it is possible to calculate the amounts of MDI and PTMG parts in the PU-prepolymer. 250g/mole is assumed for MDI, which makes 0.79 moles of MDI used in the reaction. There are two NCO-groups per MDI that could react to this, which gives 1,58 moles of NCO-groups. At the same time the PTMG has two OH-groups that could react, and each of them could react with MDI, which means that four NCO-groups will be involved in the reaction to PTMG in the prepolymer synthesis which finally gives a need of 0,39 moles of PTMG. With the recipe in mind , it looks like good assumption that the PTMG is of the type 2 000g/mole. In the curing process we have to take into account the small portions of diamines mentioned in the recipe. The recipe shows that the prepolymer will have 0,74 moles NCO-groups free for reaction with the curing substance. If each curing substance could react with one NCO-end of two prepolymers we should get 0.37 moles curing substance, or compared to the recipe a moleweight approx. 162 g/mole.

Technical system description	This set of data concerns the production of the polyurethane precursors (TDI, MDI, Polyols) and not the production of the polyurethane foam. The principal raw materials for polyurethane precursors are crude oil and natural gas. The diisocyantes having the greatest commercial importance originate from the aromatic content (benzene and toluene), while the polyols come almost exclusively from the aliphatic content. Diisocyanates are obtained by phosphogenation of daimines which are produced, via a number of intermediates steps, from aromatic hydrocarbons. The diisocyanate with the greatest technical importance are tolyene diisocyanante (TDI) and diphenylmethane diisocyanate (MDI). The polyols used in polyurethane production are predominantly hydroxy-polyesters. They are produced by alkoxylation. Depending on the degree of cross-linking required, the starting alcohols used for hydroxy-polyethers may be divalent glycols (ethylene, propylene and other glycols) or multivalent alcohols. The epoxides used are generally propylene oxide and ethylene oxide.

About Inventory

Publication	Eco profiles ot the European plastics industry Report 9 : Polyurethane precursors (TDI, MDI, Polyols) APME technical report June 1996 --- Data documented by: Sophie Louis, Volvo Technical Development Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology ---
Intended User	APME's eco-profiles serve two
General Purpose	There is an increasing demand concerning LCA data. Following this trend, ISOPA [The European Isocyanate Producers Association] members in Western Europe wanted to provide public ''Cradle to the gate data'' concerning their product's life-cycle.
Detailed Purpose	The aim here is to provide ''cradle to gate'' data for the manufacturing of MIDI (one of the precursors of PUR)
Commissioner	- ISOPA, Avenue E. van Nieuwenhuyse 4 Box 2 B 1160 Brussels.
Practitioner	Boustead, Ian Dr - .
Reviewer	
Applicability	It is important to recognise that the data do not refer only to the final conversion stages leading to the MDI but to all operations starting with raw materials in the Earth.
About Data	The transport of the different precursors to the plant where is produced polyurethane foam is not included here in this set of data. Data have been obtained from plants producing a total of 366000 tonnes of MDI monomer and polymer in 1990. The difference in the results for the monomeric and polymeric forms are insignificant and so a single average data has been produced. Data on the production processes have been supplied by ARCO Chemical, BASF, BAYER, DOW, Enichem, ICI, Rhone Poulenc and Shell relating to plants operating in Belgium, France Germany, Italy, the Netherlands, Portugal, Spain and the United Kingdom.

General Purpose	
Detailed Purpose	The data was compiled to obtain a basis to calculate the energy use and emissions of average engines installed in Swedish vessels.
Commissioner	- Swedish Transport Research Board, Swedish Maritime Administration, Swedish Shipowner Association, Swedish Environmental Protection Agency, Swedish Port Association and Board for Technical Development.
Practitioner	Alexandersson, Anders - MariTerm Göteborg.
Reviewer	
Applicability	The data was compiled to represent the energy use and emissions of average engines installed in Swedish vessels. The energy use and emissions for different engines may however vary. The data should therefore not be used as a basis to calculate the energy use and emissions of engines installed in international vessels. The emissions of particles and NOx are influenced by the fuel quality, depending on the nitrogen and sulphur content in the fuel. The development of engines has aimed to increase the efficiency of the engine, i.e. decrease the bunker consumption preserving the power outtake. This has resulted in an increase of the specific emissions of NOx, while the emissions of other parameters has decreased. The specific fuel consumption for fuel optimised four-stroke engines at normal operation at sea is 160 g/kWh. Older engines has a higher fuel consumption. The fuel quality has a large influence on the emissions of particles and NOx, depending on the nitrogen and sulphur content in the fuel. The development of engines has aimed to increase the efficiency of the engine, i.e. decrease the bunker consumption preserving the power outtake. This has resulted in an increase of the specific emissions of NOx, while the other emissions has decreased. The specific fuel consumption for fuel optimised four-stroke engines at normal operation at sea is 170-180 g/kWh. Older engines has a higher fuel consumption.
About Data	The data is based on measurements onboard sailing vessels and data from engine manufacturers.
Notes	The data was used as a basis to calculate the energy use and emissions for different vessels in the work of NGM published in Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997, NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997

SPINE LCI dataset: Medium speed, four-stroke diesel vessel engine

Administrative	
Finished	Y
Date Completed	1991-01-01
Copyright	Swedish Transport Research Board
Availability	Public

Technical System	
Name	Medium speed, four-stroke diesel vessel engine
Functional Unit	1 kWh, 20 % engine load

Functional Unit Explanation	1 kWh mechanical work done by the engine at 20 % engine load
Process Type	Unit operation
Site	Sweden
Sector	Machinery and equipment
Owner	Sweden
Technical system description	Operation of a medium speed, four-stroke diesel engine used in vessels.

System Boundaries

Nature Boundary	Regulated emissions to air are considered.
Time Boundary	The aim was that the data should represent engines in use in 1987.
Geographical Boundary	Engines used in Swedish vessels
Other Boundaries	The engine load i.e the power outtake is 20 %.
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1989-01-01 - 1990-10-01
Data Type	Derived, unspecified
Represents	SKF Gleitlager in Püttlingen, Germany
Method	The emissions at 20 % engine load are based on measurement onboard three sailing vessels performed by IVL (Swedish Environmental Research Institute), material from engine manufacturers (Wärtsilää Diesel, MaK, MAN -B&W) and other projects that has conducted measurements onboard sailing vessels. The material from the engine manufacturers is based on tests performed on the engine installed in a test bench. The data can be found in Alexandersson. The oil consumption is based on assumptions (Alexandersson).
Literature Reference	Alexandersson, A., *Sjöfartens utsläpp av avgaser*, MariTerm, TFB-rapport 1991:18
Notes	The data are partly from 1996 and partly from 1998.

SPINE LCI dataset: Medium weight truck, regional, Euro 0

Administrative	
Finished	Y
Date Completed	1998 - 08
Copyright	NTM
Availability	Public

Technical System	
Name	Medium weight truck, regional, Euro 0
Functional Unit	1 tonkm, 50 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 50 %. An utilisation level of 50 % is considered to be representative for Swedish domestic distribution traffic if *empty trips are not included.*
Process Type	Gate to gate
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of medium weight truck for regional traffic, approximately 10 m long with a curb weight of 24 tons and a maximum load of 14 tons. Fuel: diesel, MK 1 (sulphurous content: 2 ppm). Fuel consumption: high 4 l/10 km, medium 3.5 l/10 km, low 3 l/10 km. Engine type: Euro 0 (1990-1992). Utilisation level: 50% by weight.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO_2 -tax regulated CO_2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	Data are valid for trucks produced 1987 - 1992
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic. Empty trips are not included. *Parameters not considered* -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1998 - 08
Data Type	Derived, unspecified
Represents	NTM
Method	Data have been put together for NTM by a group of manufacturers and hauliers, i.e. Volvo, Scania, BTL, ASG, Swedish Hauliers Assosiation. Data are presented in relation to the transport work, in g/tonkm. The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic and 70 % for long distance transport with heavy trucks. The utilisation level is based on the load carrying weight, i.e. the weight on which the customer price is based. This means that bulky cargo is multiplied with a factor in order to compensate for taking up volume. The average break-point density is 275 kg/m3. Energy use and emissions per tonkm with a truck should be based on the load carrying weight. The *quantity value for the energy use* refer to average fuel consumption, the *maximum and minimum value* refer to changes in the fuel consumption due to degeneration, driving behavour etc.. The emissions of CO_2 and SO_2 is based on the fuel consumption. For *emissions of NOx, HC, particles and CO, The emission data have been produced through simulations conducted by Volvo Trucks and Scania in 1997. The simulations were based on certification values for engines and fuel consumption under actual operation for Swedish conditions. For medium and light lorries, the emission values have been obtained from certification values for new engines that are operated in accordance with established operating cycles, e.g. ECR-49 (IVL and Mercedes). Emissions data related to fuel consumption Emission factors (g/liter) Euro 0 Euro 1 Euro 2 Law from: 1980 1990 1993 1996 NOx 52+/- 5 44 27 23 HC 6+/- 2 2.1 1.8 1.3 PM 3+/- 2 1 0.5 0.35 CO 8+/- 3 3.7 3.4 2.5 This shows emissions factors in g/l for heavy lorries. With fuel consumption as a basis, it is possible to calculate the emissions. The data on emissions are based on measurements in accordance with applicable standards for certification. liters/100 km Empty Full load Distribution lorry (Payload 8.5 ton) 20-25 25-30 Med.-size lorry (Payload 14 ton) 25-30 30-40 Heavy lorry w trailer (Payl. 26 ton) 22-27 32-38 Heavy lorry w 2 trail. (Payl. 40 ton) 28-33 43-55*
Literature Reference	Alexandersson, A., *Sjöfartens utsläpp av avgaser*, MariTerm, TFB-rapport 1991:18
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

About Inventory	
Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	- Swedish haulages and transport companies .
Reviewer	None, to be reviewed. -
Applicability	The data should not be used for any detailed study of transport systems. More detailed information is needed in order to carry out such studies, e.g. regarding the vehicle -type -age and performance, fuel type, the nature of the goods, the utilisation level etc. For a specific transport, the company carrying out the transport should be contacted in order to get information on how the goods are handled and how the transport is carried out. Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred. The standard values presented in this activity should not be used if specific information on the fuel consumption for the transport is availiable. In this case, the fuel consumption should instead be used as a basis to calculate the emissions from the transport. See General QMetaData for emission factors that can be used to calculate emissions per litre fuel used. The age categories of the vehicles compiled in the work are: Older than 1990, Euro 0: Introduced 1987, law from 1990 Euro 1: Introduced 1991, law from 1993 Euro 2: Introduced 1993, law from 1996 However, in order to improve the accuracy of the calculations, the user ought to know the

Euro-class (emission standards) of the vehicle, rather than to base the calculations on the age of the vehicle.

Handling of goods

The data presented by NTM is representative for a terminal based transport system. The vehicles can be used in different ways, primarily altering the degree of utilisation. Several other types of road based cargo transport systems is not well described by the data (e.g. oil and excavated materials)
Terminal based road transports generally consists of 1-3 parts:
1. Collection of the goods to terminal
2. Long-distance transport between terminals
3. Distribution of the goods from terminal
The collection and distribution routes are generally performed by smaller vehicles while the inter-terminal traffic is operated by larger units, typically with a higher degree of utilisation.

--*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport.
--*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited
--*Parcel goods (<100 kg)* are normally handled in small vehicles

The following vehicles and equipages are used in terminal based transport systems in Sweden:
--*Parcel truck/van, max 3,5 tonnes* is mainly used for transportation of parcels.
--*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic.
--*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic.
--*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods.
--*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland.
--*Truck with semi-trailer, max 42 tonnes* is used for international long-distance traffic.

Utilisation level

The data is only applicable for an utilisation level of 70 % for long distance transport and 50 % for local distribution and regional transport, which is considered representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip, due to specialised vehicles). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than smaller firms of haulage. The utilisation of company internal vehicles is generally low.

The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden):
-excavated materials and round timber - 50%
-manufactured products (wholesale goods) - slightly more than 20%
-provisions and animal forage - approx. 15%
-mixed cargo (general goods) approx - 10 %.

Bulky goods

The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.

Fuel

The fuel used is diesel environmental class 1, except for petrol driven delivery vans who are assumed to use standard unleaded petrol. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (> 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions.

Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the data. NGM propose that data from Blinge et. al (Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997) should be used. This study is based on best available technology and Swedish conditions which is likely to yield a low figure.

International road transports

The data may be used for international transport if the data is recalculated for diesel environmental class 3. This will alter both the SOx emission and the regulated engine emissions. Generally the fleets in western Europe is composed of newer vehicles than in Sweden. The utilisation of the vehicles may also vary in different countries.

About Data

The emission data of medium-sized and light trucks have been collected from certification values of new engines, driven according to fix driving cycles, e.g. ECR-49 (IVL and Mercedes).

Notes	The person stated as ''Practitioner'' is the contact person for the data for truck transportation in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

The vehicles can be used in different ways, primarily altering the degree of utilisation. Several other types of road based cargo transport systems is not well described by the data (e.g. oil and excavated materials) Terminal based road transports generally consists of 1-3 parts: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles while the inter-terminal traffic is operated by larger units, typically with a higher degree of utilisation. --*Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. --*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited --*Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used in terminal based transport systems in Sweden:*** --*Parcel truck/van, max 3,5 tonnes* is mainly used for transportation of parcels. --*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. --*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. --*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. --*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. --*Truck with semi-trailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for an utilisation level of 70 % for long distance transport and 50 % for local distribution and regional transport, which is considered representative for

	Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip, due to specialised vehicles). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than smaller firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1, except for petrol driven delivery vans who are assumed to use standard unleaded petrol. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (> 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the data. NGM propose that data from Blinge et. al (Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997) should be used. This study is based on best available technology and Swedish conditions which is likely to yield a low figure. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. This will alter both the SOx emission and the regulated engine emissions. Generally the fleets in western Europe is composed of newer vehicles than in Sweden. The utilisation of the vehicles may also vary in different countries.
About Data	The emission data of medium-sized and light trucks have been collected from certification values of new engines, driven according to fix driving cycles, e.g. ECR-49 (IVL and Mercedes).
Notes	The person stated as ''Practitioner'' is the contact person for the data for truck transportation in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: Medium weight truck, regional, Euro 2

Administrative	
Finished	Y
Date Completed	1998 - 08
Copyright	NTM
Availability	Public

Technical System	
Name	Medium weight truck, regional, Euro 2
Functional Unit	1 tonkm, 50 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 50 %. An utilisation level of 50 % is considered to be representative for Swedish domestic distribution traffic if *empty trips are not included.*
Process Type	Gate to gate
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of medium weight truck for regional traffic, approximately 10 m long with a curb weight of 24 tons and a maximum load of 14 tons. Fuel: diesel, MK 1 (sulphurous content: 2 ppm). Fuel consumption: high 4 l/10 km, medium 3.5 l/10 km, low 3 l/10 km. Engine type: Euro 2 (1996-). Utilisation level: 50% by weight.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	Data are valid for trucks produced 1993 - 1999
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic. Empty trips are not included. *Parameters not considered* -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data	
General Activity QMetaData	
Date Conceived	1998 - 08
Data Type	Derived, unspecified
Represents	NTM
Method	Data have been put together for NTM by a group of manufacturers and hauliers, i.e. Volvo, Scania, BTL, ASG, Swedish Hauliers Assosiation. Data are presented in relation to the transport work, in g/tonkm. The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic and 70 % for long distance transport with heavy trucks. The utilisation level is based on the load carrying weight, i.e. the weight on which the customer price is based. This means that bulky cargo is multiplied with a factor in order to compensate for taking up volume. The average break-point density is 275 kg/m3. Energy use and emissions per tonkm with a truck should be based on the load carrying weight. The *quantity value for the energy use* refer to average fuel consumption, the *maximum and minimum value* refer to changes in the fuel consumption due to degeneration, driving behavour etc.. The emissions of CO2 and SO2 is based on the fuel

	consumption. For *emissions of NOx, HC, particles and CO, The emission data have been produced through simulations conducted by Volvo Trucks and Scania in 1997. The simulations were based on certification values for engines and fuel consumption under actual operation for Swedish conditions. For medium and light lorries, the emission values have been obtained from certification values for new engines that are operated in accordance with established operating cycles, e.g. ECR-49 (IVL and Mercedes). Emissions data related to fuel consumption Emission factors (g/liter) Euro 0 Euro 1 Euro 2 Law from: 1980 1990 1993 1996 NOx 52+/- 5 44 27 23 HC 6+/- 2 2.1 1.8 1.3 PM 3+/- 2 1 0.5 0.35 CO 8+/- 3 3.7 3.4 2.5 This shows emissions factors in g/l for heavy lorries. With fuel consumption as a basis, it is possible to calculate the emissions. The data on emissions are based on measurements in accordance with applicable standards for certification. liters/100 km Empty Full load Distribution lorry (Payload 8.5 ton) 20-25 25-30 Med.-size lorry (Payload 14 ton) 25-30 30-40 Heavy lorry w trailer (Payl. 26 ton) 22-27 32-38 Heavy lorry w 2 trail. (Payl. 40 ton) 28-33 43-55*
Literature Reference	
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

About Inventory

Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.

Practitioner	- Swedish haulages and transport companies .
Reviewer	None, to be reviewed. -
Applicability	The data should not be used for any detailed study of transport systems. More detailed information is needed in order to carry out such studies, e.g. regarding the vehicle -type -age and performance, fuel type, the nature of the goods, the utilisation level etc. For a specific transport, the company carrying out the transport should be contacted in order to get information on how the goods are handled and how the transport is carried out. Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred. The standard values presented in this activity should not be used if specific information on the fuel consumption for the transport is availiable. In this case, the fuel consumption should instead be used as a basis to calculate the emissions from the transport. See General QMetaData for emission factors that can be used to calculate emissions per litre fuel used. The age categories of the vehicles compiled in the work are: Older than 1990, Euro 0: Introduced 1987, law from 1990 Euro 1: Introduced 1991, law from 1993 Euro 2: Introduced 1993, law from 1996 However, in order to improve the accuracy of the calculations, the user ought to know the Euro-class (emission standards) of the vehicle, rather than to base the calculations on the age of the vehicle. ***Handling of goods*** The data presented by NTM is representative for a terminal based transport system. The vehicles can be used in different ways, primarily altering the degree of utilisation. Several other types of road based cargo transport systems is not well described by the data (e.g. oil and excavated materials) Terminal based road transports generally consists of 1-3 parts: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles while the inter-terminal traffic is operated by larger units, typically with a higher degree of utilisation. *--Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. *--General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited *--Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used in terminal based transport systems in Sweden:*** *--Parcel truck/van, max 3,5 tonnes* is mainly used for transportation of parcels. *--Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. *--Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. *--Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. *--Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. *--Truck with semi-trailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for an utilisation level of 70 % for long distance transport and 50 % for local distribution and regional transport, which is considered representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip, due to specialised vehicles). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than smaller firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %.

	Bulky goods The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel*** The fuel used is diesel environmental class 1, except for petrol driven delivery vans who are assumed to use standard unleaded petrol. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (> 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the data. NGM propose that data from Blinge et. al (Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. Reviewer	None, to be reviewed. -
Applicability	The data should not be used for any detailed study of transport systems. More detailed information is needed in order to carry out such studies, e.g. regarding the vehicle -type -age and performance, fuel type, the nature of the goods, the utilisation level etc. For a specific transport, the company carrying out the transport should be contacted in order to get information on how the goods are handled and how the transport is carried out. Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred. The standard values presented in this activity should not be used if specific information on

the fuel consumption for the transport is availiable. In this case, the fuel consumption should instead be used as a basis to calculate the emissions from the transport. See General QMetaData for emission factors that can be used to calculate emissions per litre fuel used.

The age categories of the vehicles compiled in the work are:
Older than 1990,
Euro 0: Introduced 1987, law from 1990
Euro 1: Introduced 1991, law from 1993
Euro 2: Introduced 1993, law from 1996
However, in order to improve the accuracy of the calculations, the user ought to know the Euro-class (emission standards) of the vehicle, rather than to base the calculations on the age of the vehicle.

Handling of goods
The data presented by NTM is representative for a terminal based transport system. The vehicles can be used in different ways, primarily altering the degree of utilisation. Several other types of road based cargo transport systems is not well described by the data (e.g. oil and excavated materials)
Terminal based road transports generally consists of 1-3 parts:
1. Collection of the goods to terminal
2. Long-distance transport between terminals
3. Distribution of the goods from terminal
The collection and distribution routes are generally performed by smaller vehicles while the inter-terminal traffic is operated by larger units, typically with a higher degree of utilisation.

--Wholesale goods (>1000 kg) are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport.
--General goods (100-1000 kg) are generally handled via terminal. The goods may be both weight and volume limited
--Parcel goods (<100 kg) are normally handled in small vehicles

The following vehicles and equipages are used in terminal based transport systems in Sweden:
--Parcel truck/van, max 3,5 tonnes is mainly used for transportation of parcels.
--Light truck, max 8 tonnes is used for local distribution, mainly in city traffic.
--Truck, max 18 tonnes is used for district distribution and local distribution in city traffic.
--Truck, max 24 tonnes is mainly used for transportation of general (styckegods) and wholesale (partigods) goods.
--Heavy truck with trailer, max 60 tonnes is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland.
--Truck with semi-trailer, max 42 tonnes is used for international long-distance traffic.

Utilisation level
The data is only applicable for an utilisation level of 70 % for long distance transport and 50 % for local distribution and regional transport, which is considered representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip, due to specialised vehicles). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than smaller firms of haulage. The utilisation of company internal vehicles is generally low.

The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden):
-excavated materials and round timber - 50%
-manufactured products (wholesale goods) - slightly more than 20%
-provisions and animal forage - approx. 15%
-mixed cargo (general goods) approx - 10 %.

Bulky goods
The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.

Fuel
The fuel used is diesel environmental class 1, except for petrol driven delivery vans who are assumed to use standard unleaded petrol. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (> 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions.

Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the data. NGM propose that data from Blinge et. al (Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997) should be used. This study is based

	on best available technology and Swedish conditions which is likely to yield a low figure. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. This will alter both the SOx emission and the regulated engine emissions. Generally the fleets in western Europe is composed of newer vehicles than in Sweden. The utilisation of the vehicles may also vary in different countries.
About Data	The emission data of medium-sized and light trucks have been collected from certification values of new engines, driven according to fix driving cycles, e.g. ECR-49 (IVL and Mercedes).
Notes	The person stated as ''Practitioner'' is the contact person for the data for truck transportation in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: Metal coating of cold reduced steel sheets

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Metal coating of cold reduced steel sheets
Functional Unit	1 kg zinc coated steel sheet.
Functional Unit Explanation	
Process Type	Unit operation
Site	SSAB Tunnplåt
Sector	
Owner	SSAB Tunnplåt
Technical system description	This activity describes a process step included in the system ''Production of plywood boxes'', also available in the SPINE@CPM database. Plywood boxes are used to pack the coated and non-coated roller bearings from SKF, Göteborg, during the transportation to customers. The plywood boxes are manufactured by Nefab Emballage AB in Alfta, Sweden. The plywood box consist of plywood, steel strips, steel nails and wooden splits. The steel for the steel strips is hot rolled, pickled, cold reduced and finally coated at SSAB Tunnplåt`s line in Borlänge. This dataset describes the metal coating of 1 kg cold reduced steel sheet at SSAB Tunnplåt AB in Borlänge.  This environmental profile refers to the mean values of emissions caused by metal coating at SSAB Tunnplåt`s line in Borlänge during the years 1997-1998. All data for the process is obtained from an earlier LCA study at Nefab Emballage AB: Hillvall Maria; Transportförpackningars bidrag till reduktion av miljöbelastningen; Master Thesis at the Technical University of Luleå; 2000.

	The data refers to an existing EPD from SSAB Tunnplåt AB: Environmental Product Declaration from SSAB; SE 520; August 1998.

System Boundaries

Nature Boundary	Emissions to air and water are included. The steel scrap from the process is reused as raw material and is thus not considered as waste, but as a co-product ending in the technosphere. For more detailed information see the EPD SE 520 from SSAB Tunnplåt AB.
Time Boundary	This environmental profile refers to the mean values of emissions caused by metal coating at SSAB Tunnplåt`s line in Borlänge during the years 1997-1998.
Geographical Boundary	The process takes place at SSAB Tunnplåt`s line in Borlänge, Sweden.
Other Boundaries	The production of electricity is NOT included in the dataset, but must be followed from the cradle in order to obtain the total environmental impact. This must also be done with the production of LPG. For more detailed information see the EPD SE 520 from SSAB Tunnplåt AB.
Allocations	Allocations have been made according to weight.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	02-08-01 - 02-12-31
Data Type	Derived, mixed
Represents	NTM
Method	The data is taken from an earlier LCA study at Nefab Emballage AB: Hillvall Maria; Transportförpackningars bidrag till reduktion av miljöbelastningen; Master Thesis at the Technical University of Luleå; 2000.
Literature Reference	[1] Source: EPD (SE 520, 1998) from SSAB for the product Dogal.
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over the year is needed, e.g. in a transport deal, which often covers a year's time. In such a case, different types of vehicles and utilisation levels may have occurred.

About Inventory

Publication	Master thesis: LCA based solution selection; Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. ------------ Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics,

	Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. Both types of bearings are packed in a plywood box. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The data is valid for metalcoating of 1 kg cold-reduced steel sheet at SSAB Tunnplåt`s line in Borlänge, Sweden.
About Data	All data for the process is obtained from an earlier LCA study at Nefab Emballage AB: Hillvall Maria; Transportförpackningars bidrag till reduktion av miljöbelastningen; Master Thesis at the Technical University of Luleå; 2000. About Inventory

Publication	Environmental report concerning the activities 1995 at Pollux Ytbehandling AB, The Environmental Administration in the municipality of Göteborg, Sweden Personal communication: Christer Dryselius, Pollux Ytbehandling AB -- Data documented by: Maria Erixson and Sara Ågren, project employed for the database project at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	To show the environmental load
General Purpose	The purpose of the Environmental report is to be the base for permission trial of activities that is harmful to the environment and further to make shore that the company comply with the decision.
Detailed Purpose	To control that the legislated limits are not exceeded.
Commissioner	- Swedish government via The Board of County in Göteborg and Bohus or The Environmental Administration in the municipality of Göteborg. .
Practitioner	Dryselius, Christer - Pollux Ytbehandling AB.
Reviewer	- Swedish government via The Board of County in Göteborg and Bohus or The Environmental Administration in the municipality of Göteborg.

Applicability	The extent of the production is not mentioned in the Environmental report. Because of this we have no functional unit which makes it impossible to use the data direct for life cycle analysis. Though, it is possible to get in touch with the company and try to get some more information. The objects that undergoes the metal surface treatment is not mentioned nor calculated for as an input. The function of the technical system is not sufficently described. Contact the company to get the necessary details.
About Data	The torrent of waste water to the sewage treatment works is 4949 m3/år. The data is representing the emission etc during a year. Legislated limits for the plant: Torrent of water from the electropolishing 0,5 m3/h Maximum temperature (Celsius) 45 pH 6,5-10,0 Ni 1,0 mg/l Cr 1,0 mg/l

About Inventory

Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow.

	When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998

SPINE LCI dataset: Mining to sodium chloride APME

Administrative	
Finished	Y
Date Completed	1994
Copyright	APME
Availability	Public

Technical System	
Name	Mining to sodium chloride APME
Functional Unit	1 kg of sodium chloride, purified
Functional Unit Explanation	Sodium chloride (NaCl) purified to a quality that can be used in the electrolysis for chlorine.
Process Type	Cradle to gate

Site	European average values, Used for identification of owner and/or site in Object of study under Technical system for activity
Sector	Materials and components
Owner	European average values, Used for identification of owner and/or site in Object of study under Technical system for activity
Technical system description	Production of sodium chloride including all major operations from extraction of raw materials from the ground to purification. There are two different methods for extraction of sodium chloride from naturally occurring salt deposits: rock salt mining and brine pumping. Data have been collected for mining of 4,15E5 tonnes of rock salt and brine pumping of some 4,1E6 tonnes of sodium chloride (solid content). In brine pumping, water is pumped into a salt deposit to produce a saturated solution of sodium chloride, which can then be pumped to the surface. The main impurities present in the brine are magnesium, calcium and sulphate ions (total concentration is typically 0,6 wt%). Magnesium and calcium ions are removed by precipitation as insoluble magnesium hydroxide and calcium carbonate, respectively. Sulphate ions can be removed by precipitaion as barium sulphate or calcium sulphate. The impurities present in mined sodium chloride are similar to those in brine, but the concentrations are usually higher. The brine purification step adds significantly to the energy requirements for sodium chloride production. The extracted sodium chloride can be transported by pumping a saturated solution along a pipeline to a plant nearby. Alternatively, it can be purified and crystallized as a solid (containing approx. 3% moisture) for transport by road or rail. Rock salt is frequently transported ''as mined'', and purified at the destination. For the electricity taken in from the public supply, most likely, the calculations have taken account of the country specific electricity production efficiency. Some more information about the processes are found in the ''Eco-profiles...'' report 6, pp 9-12.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available.'' Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since parameters that are not monitored by the companies have been estimated.
Time Boundary	The year of data collection is not explicitly stated, but it is probably 1989 and/or 1990.
Geographical Boundary	Results are based on data obtained from raw material suppliers to PVC production plants in Europe. Possibly, most of the sodium chloride production sites are also in Europe. Data were averaged over all sodium chloride production sites examined and weighted by the total production (mass) from each site; i e not only the inputs to chlorine production were considered.
Other Boundaries	No excluded subsystems are mentioned. No cut-off criteria for exclusion of minor inputs and outputs are stated.
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1990
Data Type	Derived, mixed
Represents	NTM
Method	Results are based on data from raw material suppliers to PVC production plants in Europe. Data were averaged over all sodium chloride production sites and weighted by the total production (mass) from each site. For fuels and energy, the following gross calorific values (energy content) have been used in the calculations: 45,0 MJ/kg for oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal.
Literature Reference	''Eco-profiles of the European plastics industry'' Report 6: Polyvinyl chloride, I. Boustead, APME, 1994, data from Tables 10-11. (APME = Association of Plastics Manufacturers in Europe)
Notes	As the APME substance nomenclature and the ABB database nomenclature sometimes differ, the original APME substance name is given within '''' in the flow metadata Notes field, if the name has been changed significantly. 20000111 SECRC/GM

About Inventory

Publication	''Eco-profiles of the European plastics industry'' Report 6: Polyvinyl chloride, I. Boustead, APME, 1994, data from Tables 10-11. Report 2: Olefin feedstock sources, I. Boustead, APME, 1993. Updated reports are available at APME's web site http://lca.apme.org/reports (APME = Association of Plastics Manufacturers in Europe) The APME project co-ordinator: Vince Matthews. The members of the original independent expert panel: Ian Boustead, Paul Fink, Horst Langowski, Gustav Sundstrom. -- Editor: Data entered into the SPINE format by Gunnar Mattsson, ABB Corporate Research, 2000-01-11. Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Göteborg
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	1) Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2) Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i e LCAs) of individual products. Note that the role of sodium chloride in the study is only as a raw material for production of chlorine, which is used in the production of PVC.
Commissioner	- APME, Association of Plastics Manufacturers in Europe Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels .
Practitioner	Boustead, Ian - .
Reviewer	
Applicability	The data are calculated on a cradle to gate basis, therefore, no supplier activities should be connected to, e g, nuclear power, coal and limestone.
About Data	Data for sodium chloride production are included in the European average data for PVC production, which were issued by APME (Association of Plastics Manufacturers in Europe) and produced in association with the independent expert I. Boustead. The number of producers is not stated, only the volumes of produced sodium chloride (4,15E5 tonnes + 4,1E6 tonnes). Hence, whether the data are representative for production of sodium chloride in Europe is not known. However, the data quality is dependent on the quality of the records maintained by the individual companies. Site-specific data for raw materials and fuels have been used when available. Data from other manufacturers have been used in other cases. The quality of data for public electricity production is not described. For fuels and energy, the following gross calorific values (energy content) have been used in the calculations: 45,0 MJ/kg for oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal.

Technical System	
Name	Mining to sodium hydroxide APME
Functional Unit	1 kg of sodium hydroxide
Functional Unit Explanation	Sodium hydroxide (NaOH) produced by sodium chloride electrolysis and concentrated to about 50 wt%.
Process Type	Cradle to gate
Site	European average values, Used for identification of owner and/or site in Object of study under Technical system for activity
Sector	Materials and components
Owner	European average values, Used for identification of owner and/or site in Object of study under Technical system for activity
Technical system description	Production of sodium hydroxide including all major operations from extraction of raw materials (mainly sodium chloride) from the ground, to co-production of chlorine, sodium hydroxide and hydrogen by electrolysis, and concentration of the sodium hydroxide solution. There are two different methods for extraction of sodium chloride from naturally occurring salt deposits: rock salt mining and brine pumping. The data for mining/extraction and purification of sodium chloride are available in a separate data set. Sodium chloride electrolysis: 2 NaCl(aq) + H2O = 2 NaOH(aq) + Cl2(g) + H2(g) Three different electrolytic cells are used: the amalgam or mercury cell, the diaphragm cell and the membrane cell. In the mercury cell, the cathode consists of mercury flowing across the cell floor. Saturated sodium chloride solution flows above the cathode. At the anode, chloride ions are oxidised to chlorine gas, which is collected and taken from the cell. At the cathode, sodium ions are reduced to form sodium metal, which forms an amalgam with the mercury. The amalgam is removed from the cell and sent to a separate reactor where the sodium in the amalgam is reacted with water to form sodium hydroxide and hydrogen gas. In the diaphragm and membrane cells, the anode and cathode compartments are separated. The sodium chloride solution is contained within a diaphragm or a membrane. In this anode compartment, chlorine gas is evolved. At the cathode mesh outside the diaphragm/membrane, water is reduced to hydrogen gas, leaving a sodium hydroxide solution. Data have been obtained from 14 chlor-alkali plants producing some 2,4E6 tonnes of chlorine and 1,95E6 tonnes of sodium hydroxide. For the electricity taken in from the public supply, most likely, the calculations have taken account of the country specific electricity production efficiency. Some more information about the processes are found in the ''Eco-profiles...'' report 6, pp 9-15, and also in report 5.

System Boundaries	
Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available.'' Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since parameters that are not monitored by the companies have been estimated.
Time Boundary	The year of data collection is not explicitly stated, but it is probably 1989 and/or 1990.
Geographical Boundary	Results are based on data obtained from raw material suppliers to PVC production plants in Europe. Possibly, most of the chlor-alkali production sites are also in Europe. Data were averaged over all chlor-alkali production sites and weighted by the output from all of the producers.
Other Boundaries	No excluded subsystems are mentioned. No cut-off criteria for exclusion of minor inputs and outputs are stated.

Allocations	The inputs and outputs associated with the operation of the electrolysis plants have been partitioned between the different co-products chlorine, sodium hydroxide and hydrogen in the following way: 1) Sodium chloride raw material has been partitioned between chlorine and sodium hydroxide on the basis of the relative atomic masses of Na and Cl: 39,3% to sodium hydroxide, 60,7% to chlorine. 2) The thermal energy has been totally attributed to sodium hydroxide. 3) The electricity has been partitioned on a mass basis using the masses of the products sodium hydroxide, chlorine and hydrogen: 52,3% to sodium hydroxide, 46,4% to chlorine, 1,3% to hydrogen. 4) All emissions are treated as arising from all of the products of the plant and have, thus, been partitioned across all products on a mass basis: 52,3% to sodium hydroxide, 46,4% to chlorine, 1,3% to hydrogen. The allocation is discussed thoroughly in the ''Eco-profiles...'' report 5.

About Inventory

Publication	This process is included in the system described in: Kilgus D, 2005, Life cycle assessment of a demonstration project - vehicle use of hydrogen-blended natural gas. Environmental Systems Analysis report 2005:16, Chalmers University of Technology, Gothenburg, Sweden Link to pdf (in Swedish): http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2005--16.pdf
Intended User	LCA practitioners.
General Purpose	This data set is included in a master thesis. Excerpt from the master thesis abstract: ''Hydrogen is often considered as the way out of the environmental and economical problems associated with the use of fossil fuels. However, one of the main implementation barriers is the missing infrastructure. The introduction of hydrogen-blended compressed natural gas (HCNG) as a fuel for natural gas vehicles could serve as a bridging technology by using the existing natural gas infrastructure for the distribution of hydrogen.''
Detailed Purpose	Excerpt from the master thesis abstract: ''The purpose of this thesis is to assess and compare the environmental aspects of using natural gas, HCNG with 15% and 30% hydrogen by volume, and hydrogen as vehicle fuels within the scope of the proposed demonstration project.'' Excerpt from the report (see 'Publication'): ''Since 2001, the Arizona Public Service (APS), in cooperation with Electric Transportation Applications (ETA) and the U.S. Department of Energy's Advanced Vehicle Testing Activity (ATVA), has tested different vehicles operated on CNG, HCNG and hydrogen.''
Commissioner	Not applicable - .
Practitioner	Daniel Kilgus - .
Reviewer	Karl Jonasson -
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries'.
About Data	Excerpt from the report (see 'Publication'): ''Since 2001, the Arizona Public Service (APS), in cooperation with Electric Transportation Applications (ETA) and the U.S. Department of Energy's Advanced Vehicle Testing Activity (ATVA), has tested different vehicles operated on CNG, HCNG and hydrogen. Although the tested vehicles are not commonly found on Swedish roads, the test results were used since it is assumed that comparable results of other vehicle types would mainly differ by quantity.'' ____ ESA Database Project. Years: 2009-2011. Documentation completed for this data set: 2010-11-16 Administering organisation: Chalmers University of Technology, the division of Environmental Systems Analysis. Financier: The Swedish Research Council. Documentor of data: Filippa Fuhrman (ESA). Review committee for documented data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	Not applicable.

SPINE LCI dataset: Mounting of bearing

Technical System	
Name	Mounting of bearing
Functional Unit	1.2 ton of bearing
Functional Unit Explanation	One SKF spherical roller bearing size 232/530 weighs 1.2 ton.
Process Type	Unit operation
Site	Stora Enso Hylte ABHylte Mill S- 314 81 HYLTEBRUK Sweden
Sector	Construction
Owner	Stora Enso Hylte ABHylte Mill S- 314 81 HYLTEBRUK Sweden
Technical system description	This activity describes Mounting of bearing. The bearing is mounted on a soft calender roll at Stora Enso, using a manual hydraulic pump and a small amount of lubricant.

System Boundaries	
Nature Boundary	Neither the bearings or the lubricant enters from or leaves to the nature. Emissions are not included due to lack of data.
Time Boundary	Data is collected autumn 2002. Mounting of a bearing takes place every 4.5 year at Hyltebruk.
Geographical Boundary	This mounting procedure is performed at Storaenso at Hyltebruk, Sweden.
Other Boundaries	Manufacturing of lubricant is not included.
Allocations	See Notes in Flow Meta Data.
Systems Expansions	Not applicable

Sector	Materials and components
Owner	Plannja AB Svartön, Svartövägen 1 971 88 Luleå Sweden
Technical system description	Dipgalvanized steel coils and aluminum coils is painted and profiled. In the production process, sheet metal is processed into trapezium sheet metal (read mounting profile) for use as constructional members and as wall and roof covering in both domestic and industrial buildings. Train to the plant delivers hot dipgalvanized steel coils and aluminum coils, where it is painted and profiled (transports are not considered in this set of data). About 90% the total production (both steel and aluminum) is painted. Steel is the most important raw material in the process; aluminum stands for about 6% of the

	weight of total production.

System Boundaries

Nature Boundary	Emissions to air and water Emissions to air are omitted since they occur mainly from the painting process and the product of this study is assumed not to be painted. Flue gases are incinerated. Emissions to water are regarded as negligible.
Time Boundary	
Geographical Boundary	Sweden
Other Boundaries	The environmental load for chemicals and electricity is not traced back to the cradle.
Allocations	The environmental impact is equally distributed on produced weight of trapezium sheet metal (including both aluminum and steel sheets).
Systems Expansions

About Inventory

Publication	LCA of Building Frame Structures Environmental Impact over the Life Cycle of Concrete and Steel frames; Björklund T., Jönsson Å., Tillman A-M.; Report 1996:8; TEP; CTH; Göteborg; Sweden -- Data documented by: Maria Erixon, project employed for the database project at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Thomas Björklund, Technical Environmental Planning, Chalmers University of Technology --
Intended User	To make an LCA of building fra
General Purpose	Among others, to analyse and assess the environmental impact of structural concrete and steel frames in buildings during the whole life cycle by using the method of LCA as a tool.
Detailed Purpose	To calculate the environmental load of mounting profile
Commissioner	- Finncement and Trätek (The Swedish Institute for Wood Technology Research) Box 5609 S-114 86 Stockholm Sweden.
Practitioner	Björklund T., Jönsson Å., Tillman A-M - Technical Environmental Planning, CTH Sven Hultins Gata 8 412 96 Göteborg Sweden .
Reviewer	

Applicability	The environmental load for Z-profile can be approximated with the one for mounting profile. To calculate the total environmental load for mounting profile, including the sheet steel production, you can use the data in this Database at: Name: Swedish sheet steel mix Category: Other Publication: LCA of Building Frame Structures Environmental Impact over the Life Cycle of Concrete and Steel frames; Björklund T., Jönsson Å., Tillman A-M.; Report 1996:8; Technical Environmental Planning; Chalmers University of Technology, Göteborg, Sweden
About Data	Raw materials SSAB Tunnplåt delivers 95% of the hot dipgalvanized steel coils, and it is assumed in the calculations that all steel coils come from SSAB Tunnplåt. It is assumed that no paint is used for trapezium sheet steel in light decks, and paints used in the process are therefore omitted. The most important chemicals used in this process are bounders, flocculation chemicals, sulphuric acid and lubricants. Chemicals are regarded as non-elementary flows. All steel scrap (about 1% of incoming raw materials) goes back to SSAB Tunnplåt for recycling and is therefore not included. Energy use Steam and hot water is externally produced. For estimating the energy use of steam production an energy use of 2.26 MJ/kg is assumed, which is the entalphy for steam production from water. Transports The steel sheets are transported from SSAB Tunnplåt in Borlänge to Luleå by railway, and the distance is estimated to 865 km. It is not considered in this set of data.

SPINE LCI dataset: Natural gas fired combination plant for heat and power production

Administrative	
Finished	Y
Date Completed	1999-08-30
Copyright	
Availability	Public

Technical System	
Name	Natural gas fired combination plant for heat and power production
Functional Unit	1 kWh produced and delivered heat.
Functional Unit Explanation	The emissions and use of resources and raw materials are associated with the net production of 1 kWh heat.
Process Type	Gate to gate
Site	Sweden
Sector	Grid electricity and district heat
Owner	Sweden
Technical system description	BRIEF DESCRIPTION: This technical system describes the combustion process in a natural gas fired combination plant for heat and power production in Sweden. The plant consists of one gas turbine, one steam boiler and one back pressure steam turbine. The heat is delivered to a district heating net. Production of materials, chemicals, electricity and transport used in association with the fuel chain and the operation and maintenance of the plant are not included. TECHNICAL DATA FOR THE STUDIED PLANT: Average annual time of use (hour): 8 285 Total electric power output (MW): 8,2 Total thermal output (MW): 51 Annual total use of fuel (MWh): 247 190 Normal annual production of heat (MWh): 212 000

	Normal annual production of electricity (MWh): 24 000 Degree ofthermal effieciency (%): 95 PROCESS DESCRIPTION: The unit consists of one gas tubine, one steam boiler and one back pressure steam turbine. The gas turbine is equiped with water injection and the burner of the boiler has a shape that keep the emission of NOx low. The maximum thermal output is 51 MW. The heat is delivered to a district heating net. INCLUDED OPERATIONS: The process study consists of the following operations: - The feeding of the natural gas into the combustion process. - The combustion process. - The production of heat (and electricity). - The internal consumption of electricity. - The NOx control system. NOx CONTROL SYSTEM: The burner of the boiler is of low-NOx type, which yields a low NOx-value (in this case 65 mg/MJ). OTHER FLUE GAS CLEANING SYSTEMS: Combustion of natural gas will not give rise to any sulphur or dust emissions. The plant is therefor not equipped with any further gas cleaning system.

System Boundaries

Nature Boundary	CRITERIAS USED FOR SELECTING FLOWS: Most data for reported in- and outflows are normally measured and reported once yearly in a public environmental report. According to experience the emission of HC are close to zero (not measurable) when natural gas is fired.
Time Boundary	APPLICABLE TIME OF SYSTEM: This inventory was conducted using data from 1996. The data consist of average data on a year basis. This data is assumed to be valid until new national or local regulations are enforced in Sweden.
Geographical Boundary	GEOGRAPHICAL EXTENSION: This inventory has been conducted on a natural gas fired plant for heat and power production in Sweden, with swedish regulaitons, applicable during 1996. The collected data should only be used for swedish conditions.
Other Boundaries	NOTES OF EXCLUDED TECHNICAL SYSTEMS: The following operations have been excluded from the system: - The distribution of district heat and electricity from the plant to the consumers. - Building of the plant, the district heating net or the electricity supply system. - The cradle to gate of the internal electricity consumption. - The production of natural gas. - The transportation of natural gas to the plant. EXCLUDED FLOWS - The chemicals used for feed water treatment. - The water consumption in the process.
Allocations	PRINCIPLE APPLIED: In a combined heating and power plant two products of economic value are produced, heat and electrical power. For operation and maintenance of the plant the use of resources and the emissions are associated in relation to the net production of heat and power respectively. For the use of resources and emissions that are specific for the electrical power production are allocated to that production. Equivalent to this the use of resources and emissions specific for the heat production are allocated to that product. Note: When both heat and power are produced the allocation between the products are the same. That is the environmental load for 1 kWh produced heat are the same as for 1 kWh produced electrical power. DESCRIPTION:
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1996
Data Type	
Represents	The data for mounting profile has been approximated with the production of trapezium sheet steel.

Method	All data reported are related to the functional unit 1 kWh heat produced and delivered. The data is originally given as total yearly amount of an input (fuel, electricity etc.) to or an output (emission, product) from the energy plant. The inputs and outputs are the related to the functional unit by dividing the total yearly amount with the yearly amount of produced heat and multiplying with the fraction of the total production that are associated with the heat production. For some flows specific information is given, see each flow.
Literature Reference	Data is in general recieved from ''Miljörapport 1996, Vattenfall AB värme västsverige''.
Notes	The parameters presented are chosen because they are available in the annual environmental report of the plant. Data can be missing if it is not reported in the report. The type of data reported is governed by the inspection authority. All values are reported with 3 figures. The data are however seldom that accurate.

About Inventory

Publication	LCA värme, Vattenfalls Livscykelanalyser, Produktion av värme; Maria Münter, Emanuel Nandorf, Pernilla Strömberg, Andrea Wallenius; SwedPower AB, Miljö & Kvalitet; 1999-07-01. -- Data documented by: Maria Münter, Emanuel Nandorf, Pernilla Strömberg, Andrea Wallenius, Birgitta Olanders at SwedPower AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	Intended users of the data are
General Purpose	The general purpose of the inventory was to obtain a lifecycle inventory of heat producing plants using different types of fuels. A further purpose was to obtain data from heat producing plants with different capacities.
Detailed Purpose	The specific purpose was to compare data from plants producing heat with various fuels, combustion technologies and flue gas systems.
Commissioner	Bodlund, Birgit - Vattenfall AB.
Practitioner	- SwedPower AB, Maria Münter, Emanuel Nandorf, Pernilla Strömberg, Andrea Wallenius, Birgitta Olanders .
Reviewer	Pålsson, Ann-Christin - CPM Technical Environmental Planning Chalmers University of Technology 412 96 Göteborg
Applicability	CERTAIN CAUTIONS: This inventory was conduced using data mainly from 1996. The data consists of average data on a year basis. This data is assumed to be valid until new national or local regulations are enforced in Sweden. The data for this system should only be used on plants in Sweden and for swedish conditions and regulations. When both heat and power are produced the allocation between the products are the same.

	That is the environmental load for 1 kWh produced heat are the same as for 1 kWh produced electrical power.
About Data	GENERAL DATA SOURCE DESCRIPTION: Data quality in the meaning good precision for the operation of the plant concerning for example the precision of emission measurements, calibration of instruments are good for plants larger than 10 MW and/or plants with a production larger than 25 GWh/year. These plants are included in the NOx control system . At these plants the instruments for NOx-control and calculations are controlled every year at the periodical inspection. Most larger plants are also calibrating other instruments in there own interest or as a consequence of an internal control program.

Technical System	
Name	Natural gas fired combination power plant with support systems
Functional Unit	Net production of 1 kWh electricity
Functional Unit Explanation	The emissions and use of resources and raw materials are associated with the production of 1 kWh electricity.
Process Type	Cradle to gate
Site	
Sector	Grid electricity and district heat
Owner	
Technical system description	The studied system include *extraction and transport of natural gas and operation and maintenance of a modern natural gas fired combination power plant.* The plant uses a combination of gas turbine and steam turbine. A combination plant has a significantly higher degree of efficiency than both a conventional gas turbine and a power plant with a conventional steam turbine. The fuel is extracted in the North sea. Production of materials, chemicals and electricity and transports, used in association with the fuel chain and the operation and maintenance of the plant are included. The *fuel production* include extraction of natural gas from the Norwegian Ekofisk-field, maintenance and reinvestments of the oil platform and compression and transport of the natural gas in pipe line to the power plant. The share of construction and maintenance of the Danish pipe-line Nybro-Dragör (20 %) and the Swedish pipe line Dragör-Varberg (40%) that can be assigned to the gas combination power plant have also been included. Light weight oil are assumed as *reserve fuel and emergency fuel*. Oil are only used in exceptional cases, at disturbances in the supply of natural gas or inspection of the natural gas system; on average 100 hours per year. The power plant will not operate on oil and natural gas simultaneously. *Technical data* for the studied plant: Time of use, recalculated to full effect (hours): 7000 Supplied fuel effect (MW): 877 Annual total fuel use (TWh): 6,14 Normal annual production of electricity (GWh): 3255 Assumed life-time (years): 40

	Electricity production, net during 40 years (TWh): 130,2 Degree of efficiency (%): 53

System Boundaries	
Nature Boundary	The analysis starts at the *extraction of natural gas*. The gas is then followed through pipe-lines to the plant. All emissions are considered equivalent, independent of where they take place (locally, regionally, globally; in densely populated areas or rural areas).
Time Boundary	The power plant is assumed to operate during 40 years.
Geographical Boundary	The power plant are located in the south-west of Sweden. The fuel used in the plant are extracted from the Norwegian continental-shelf and transported to the and pipe-line to the power plant.
Other Boundaries	The studied system include *extraction and transport of natural gas and operation and maintenance of a natural gas fired combination plant.* Calculations of building and demolition of the plant has been performed but are not included in this system. ***Sub-systems included in the studied system:*** • Use of resources and emissions associated with reinvestments and reconstruction. Concrete constructions and buildings are however not considered to need renewal during the lifetime of the power station. • Emissions to air and water and use of energy and materials, and rest products in association with drilling and extraction of gas and maintenance and reinvestments of the oil platform. • Energy use and emissions in association with compression and transport of the natural gas in pipe line. • The share of construction and maintenance of the Danish pipe-line Nybro-Dragör (20 %) and the Swedish pipe line Dragör-Varberg (40%) that can be assigned to the gas combination power plant. • Known use of chemicals are accounted for. In the cases where it was possible to obtain data, resource use and emissions for the production are included. • Use of resources and emissions to air from production of the electricity that is used in the life cycles. • Energy use and emissions for the production of oil for the studied manufacturing processes and transports. ***Sub-systems excluded from the system:*** • Construction and demolition of plants and production platforms and pipe-lines from Norway to Denmark. • Prospecting of gas and construction of platforms and existing gas pipe-lines in the North sea. • Equipment after the power station transformer are not included. • Waste and rest products are transported to final waste. Operation and chemical and biological decomposing processes (nedbrytningsprocesser) in the final waste have not been considered. • The risk of major accidents and rare breakdowns and environmental consequences from these. • Work environment. • Environmental loads caused by the operation personnel.

Allocations	The *50/50 method* has been applied throughout the calculations. The method is described in ''Nordic Guidelines on Life-Cycle Assessment'', Nord 1995:20, The Nordic Council, Stockholm.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	
Data Type	Derived, unspecified
Represents	The data for mounting profile has been approximated with the production of trapezium sheet steel.
Method	An analysis of the fuel production, operation and maintenance of a gas-fired combination plant
Literature Reference	Brännström-Norberg B-M., Dethlefsen U., Johansson R., Setterwall C., Tunbrant S.,''Livscykelanalys för Vattenfalls elproduktion - Sammanfattande rapport'', in Swedish, Vattenfall AB
Notes	The parameters that are presented are chosen because they have a general interest and because the basis for these parameters are relatively good. All values are reported with 3 figures. The data are however seldom that accurate. Combustion of gas are responsible for the largest share of emissions of CO2 and NOx during operation of the plant. Steel and copper are replaced, and the manufacture of these materials and ammonia are responsible for a large share of NOx, SO2 and CO2 emissions. Production of ammonia is very energy demanding. The production of natural gas causes relatively large emissions. The emissions of NOx from fuel production are actually larger than from the operation of the plant.

About Inventory

Publication	Brännström-Norberg B-M., Dethlefsen U., Johansson R., Setterwall C., Tunbrant S.,''Livscykelanalys för Vattenfalls elproduktion - Sammanfattande rapport'', Vattenfall AB -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	The data can be used as a basi
General Purpose	• The work with life-cycle analysis are expected to *contribute to a reinforcement and structuring* of the environmental work within Vattenfall, and a deeper knowledge on the use of resources and emissions to the environment. • An LCA can *facilitate a need for reliable data for electricity production.* Electricity is used in the manufacture of almost every product, and data from an LCA can be used when conducting an LCA on products. • An LCA can *facilitate a choice between different techniques* for future electricity production. • An LCA can also help to *choose the most effective alternatives* to reduce the consumption of resources and environmental influence of the current electricity production system. • It is also possible to *compare* the environmental load for different alternatives of electricity production.
Detailed Purpose	To obtain a *reliable basis* to be able to perform life-cycle analyses of different types of electricity use, and to identify opportunities for improvements in the existing system. To identify data gaps and areas where the knowledge are poor.
Commissioner	- Vattenfall Elproduktion .
Practitioner	- Vattenfall Energisystem AB: Britt-Marie Brännström-Norberg Ulrika Dethlefsen Roland Johansson Caroline Setterwall Sofie Tunbrant .
Reviewer	- Thomas Ekvall, Chalmers Industriteknik (CIT) Gunnar Lindfors, Institutet för Vatten- och Luftvårdsforskning (IVL) Göran Finnveden, Institutet för Vatten- och Luftvårdsforskning (IVL)
Applicability	The studied system include extraction and transport of natural gas and operation and maintenance of a natural gas fired combination plant. The choice of the plant and technique studied make the analysis *representative for the operation and maintenance of a modern natural gas fired combination power plant.* The plant uses a combination of gas turbine and steam turbine. A combination plant has a significantly higher degree of efficiency than both a conventional gas turbine and a power plant with a conventional steam turbine. The choice of emission data has a major influence on the result. This is determined at the permit consideration for a plant and varies between both plants and countries. Relatively strict regulations have been chosen and a high but realistic degree of efficiency. Transmission and distribution losses are not included. When the result is used to study different types of electricity use, these losses should be included. A rough estimate are that the distribution losses for a large industry customer are approximately 5% of the bought electricity, i.e. to obtain data for the use of electricity the data should be multiplied with 1,05. For an average household customer the

	transmission losses are approximately 10% of the bought electricity, i.e. the data should be multiplied with 1,10. The fuel is *extracted in the North sea.* The data used for the extraction of gas are representative of the Norwegian gas fields in use today. The data for Norwegian gas extraction will however not be representative for the power plants in use in 2000. The gas field opened in 1995 will account for the larger share of future Norwegian gas deliveries. Emissions of CO2 and NOx per produced energy gas from Norwegian gas fields in 2000 are assumed to be reduced with 35% and 25% respectively, in relation to the data from 1991. The complete study include building, operation and maintenance, and demolition of the power plant and fuel production. When the data is used for energy production in a life cycle analysis of a product or a system, that do not require expansion of the electricity production system, it however reasonable only to include fuel production and operation and maintenance. The other phases of the life cycle are the same independent on the electricity production.
About Data	Errata: According to Vattefall, the fuel chain has been miscalculated. Transports have been accounted for twice. No corrections have yet been made to the database, but will be inserted as soon as the correct calculation have been obtained from Vattenfall. Data for the use of resources and energy for operation of the power stations are specific for one of Vattenfall¦s prospected gas combination power plants. The fuel are assumed to consist of a quality equivalent to the quality of the natural gas extracted from the Norwegian Ekofisk-field. Light weight oil have been assumed as reserve fuel and emergency fuel. Relevant data for transports, extraction and production of metals and chemicals, and manufacture and work on important components were hard to obtain. Data from manufacturers and other reports and studies, primarily life cycle analyses have been used. Production of material and transports are considered with current technology. Swedish standard values have been used to calculate fuel use and emissions from transports. Transport distances are specific for the operation of the plant. *The parameters that are presented* are chosen because they have a general interest and because the basis for these parameters are relatively good. All values are reported with 3 figures. The data are however seldom that accurate. Use of resources and emissions associated with *reinvestments and reconstruction* are generally assumed to give an addition of 1 % per year of the use of resources and emissions at the building phase. Concrete constructions and buildings are however not considered to need renewal during the lifetime of the power station. The following data has been used in the analysis (tonnes per year during 40 years): Steel. 48,80 Copper: 4,0 Stone wool: 2,1 Titanium: 4,4 Aluminium: 0,25 PVC: 0,29 Ammonia: 2000 The value have been corrected from the report. Hydrazine: 8,0 Hydrochloric acid (30%): 0,025 Sodium hydroxide (45%): 1,0 Iron chloride (12%): 20,0 Polymers: 30,0 The following *emission factors* have been assumed to calculate the emissions to air from operation of the power plant: NOx: 10,00 mg/MJ; 6,80e-2 g/kWh produced electricity SO2: 0,40 mg/MJ; 2,72e-3 g/kWh produced electricity CO: 10,00 mg/MJ; 6,80e-2 g/kWh produced electricity Particles (reserve fuel): 3,00 mg/MJ; 2,98e-4 g/kWh produced electricity CO2: 57000 mg/MJ; 3,87e2 g/kWh produced electricity NH3: 2,20 mg/MJ; 1,50e-2 g/kWh produced electricity CH4: 2,00 mg/MJ; 1,36e-2 g/kWh produced electricity For electricity used in the manufacture of materials and fuels, *average electricity* for the respective countries distributed on the different electricity production alternatives have been used. The following degrees of efficiencies have been used to calculate the fuel used in the electricity production. The values are standard values for existing power plants. New modern plants have often higher degrees of efficiencies. The values are calculated from the effective heat value in the used

	fuels and the energy content in the steam produced in a nuclear power plant. • Coal condensing: 40% • Oil condensing: 40% • Natural gas condensing/combination: 40% • Gas turbine: 25% • Combined heat and power plant(irrespective of fuel) 30% (for electricity production) 85% (total, for electricity and heat production) • Water power: are not recalculated, are accounted for as kWh electricity • Nuclear power: 33%, are however not recalculated, but accounted for as kWh electricity or gram natural uranium.

SPINE LCI dataset: Natural gas fired plant for heat production - Small plant

Administrative	
Finished	Y
Date Completed	1999-08-30
Copyright	
Availability	Public

Technical System	
Name	Natural gas fired plant for heat production - Small plant
Functional Unit	1 kWh produced and delivered heat.
Functional Unit Explanation	The emissions and use of raw materials are associated with the net production of 1 kWh heat.
Process Type	Gate to gate
Site	Sweden
Sector	Grid electricity and district heat
Owner	Sweden
Technical system description	BRIEF DESCRIPTION: This technical system describes the incineration process in a natural gas fired plant for heat production. Heat is produced and delivered to a district heating net. Production of materials, chemicals, electricity and transport, used in association with the fuel chain and the operation and maintenance of the plant are not included. TECHNICAL DATA FOR THE STUDIED PLANT: Average annual time of use (hours): 8460 Total thermal output (MW): 3,5 Annual total fuel use (MWh): 8 350 Normal annual production of heat (MWh): 7 920 Degree of thermal efficiency (%): 95 PROCESS DESCRIPTION: The unit consists of a steam boiler for heat production. The maximum thermal output is 3,5 MW. No activities has been made for reducing the NOx emission. INCLUDED OPERATIONS:

	The process studied consists of the following operations: - The feeding of the natural gas into the combustion process. - The combustion process. - The production of heat. - The internal consumption of electricity. NOx CONTROL: The boiler is not equiped with any NOx control system. OTHER FLUE GAS CLEANING SYSTEMS: Natural gas leaves no sulphur oxides or dust as emissions and therfore no cleaning of the flue gas is done.

System Boundaries

Nature Boundary	CRITERIAS USED FOR SELECTING FLOWS: Most data for reported in- and outflows are normally measured and reported once yearly in a public environmental report. According to experience the emission of HC are close to zero (not measurable) when natural gas is fired.
Time Boundary	APPLICABLE TIME OF SYSTEM: This inventory was conducted using data from 1996. The data consists of average data on a year basis. This data is assumed to be valid until new national or local regulations are enforced in Sweden.
Geographical Boundary	GEOGRAPHICAL EXTENSION: This inventory has been conducted on a natural gas fired plant for heat production in Sweden, with swedish regulations, applicable during 1996. The collected data should only be used for swedish conditions.
Other Boundaries	NOTES OF EXCLUDED TECHNICAL SYSTEMS: The following operations have been excluded from the system: - The distribution of district heat from the plant to the consumers. - Building of the plant, the district heating net and the electricity supply system. - The cradle to gate of the internal electricity consumption. - The production of natural gas. - The transportation of natural gas to the plant. EXCLUDED FLOWS - The chemicals for feed water treatment. - The water consumption in the process.
Allocations	PRINCIPLE APPLIED: In a heating plant one product of economic value is produced. For operation and maintenance of the plant the use of resources and the emissions are associated with the net production of heat. DESCRIPTION:
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1996
Data Type	
Represents	The data for mounting profile has been approximated with the production of trapezium sheet steel.
Method	All data reported are related to the functional unit 1 kWh heat produced and delivered. The data is originally given as the total yearly amount of an input (fuel, chemical, electricity etc.) to or an output (emission, product) from the energy plant. The inputs and outputs are then related to the functional unit by dividing the total yearly amount with the yearly amount of produced heat. For some flows specific information is given, see each flow.
Literature Reference	Data are in general recieved from ''Miljörapport 1996, Göteborg Energi AB''.
Notes	The parameters presented are chosen because they are available in the annual environmental report of the plant. Data can be missing if it is not reported in the report. The type of data reported governed by the inspection authority. All values are reported with 3 figures. The data are however seldom that accurate.

Technical System

Name	Natural gas fired plant with flue gas condensation for heat and power production
Functional Unit	1 kWh produced and delivered heat.
Functional Unit Explanation	The emissions and use of raw materials are associated with the net production of 1 kWh heat.
Process Type	Gate to gate
Site	Sweden
Sector	Grid electricity and district heat
Owner	Sweden
Technical system description	BRIEF DESCRIPTION: This technical system describes the incineration process in a modern natural gas fired plant for heat and power production in Sweden. The plant consists of two steam boiler units and is also equipped with a flue gas condensation system, to recieve more heat from the fuel. The heat is delivered to a district heating net. The plant also produces some electricity. TECHNICAL DATA FOR THE STUDIED PLANT: Average annual time of use (hours): 4141 Total electric power output (MW): 21+14 Total thermal output (MW): 43+42 Flue gas condensation capacity (MW): 15 Annual total fuel use (MWh): 517 469 Normal annual production of electricity (GWh): 110 919 Normal annual production of heat (GWh): 386 658 Degree of thermal efficiency (%): 96 PROCESS DESCRIPTION: The natural gas is incinerated in two steam boiler units. Steam is produced and transformed into electricity in a steam turbine/generator and into heat in a condensor and in some other steps. Some heat is also generated in the flue gas condensation system, when the moisture in the fuel condensates. Oil is used as reserve fuel, but is not included in this system. INCLUDED OPERATIONS: The process study consists of the following operations: - The feeding of the natural gas into the combustion process. - The combustion process. - The production of heat and (electricity). - The internal consumption of electricity. - The NOx contorl system. NOx CONTROL: The burners of the boilers are of low-NOx type, which yields a low NOx-value. OTHER FLUE GAS CLEANING SYSTEMS: Natural gas leaves no sulphur oxides or dust as emissions and therefore no cleaning of the flue gas is done.

System Boundaries

Nature Boundary	CRITERIAS USED FOR SELECTING FLOWS: Most data for reported in- and outflows are normally measured and reported once yearly in a public environmental report. According to experience the emission of HC are close to zero (not measurable) when natural gas is fired.
Time Boundary	APPLICABLE TIME OF SYSTEM: This inventory was conducted using data from 1996. The data consist of average data on a year basis. This data is assumed to be valid until new national or local regulations are enforced in Sweden.
Geographical Boundary	GEOGRAPHICAL EXTENSION: This inventory has been conducted on a natural gas fired plant for heat production in Sweden, with swedish regulations, applicable during 1996. The collected data should only be used for swedish conditions.

Other Boundaries	NOTES OF EXCLUDED TECHNICAL SYSTEMS: The following operations have been excluded from the system: -The use of reserve fuel (oil). -The distribution of district heat and electricity from the plant to the consumers. -Building of the plant, the district heating net or the electricity supply system. -The cradle to gate of the internal electricity consumption. -The production of natural gas. -The transportation of natural gas to the plant. EXCLUDED FLOWS -The water consumption in the processes.
Allocations	PRINCIPLE APPLIED: In a combined power and heating plant two products of economic value are produced. For operation and maintenance of the plant the use of resources and the emissions are associated in relation to the net production of heat and power respectively. For the use of resources and emission that are specific for the electric power production are allocated to that production. Equivalent to this the use of resources and emissions specific for heat production are allocated to that production. Note: When both heat and power are produced the allocation between the products are the same. That is the environmental load for 1 kWh produced heat are the same as for 1 kWh produced electrical power. DESCRIPTION:
Systems Expansions	N/A

That is the environmental load for 1 kWh produced heat are the same as for 1 kWh produced electrical power.
About Data	GENERAL DATA SOURCE DESCRIPTION: Data quality in the meaning good precision for the operation of the plant concerning for example the precision of emission measurements, calibration of instruments are good for plants larger than 10 MW and/or plants with a production larger than 25 GWh/year. These plants are included in the NOx control system . At these plants the instruments for NOx-control and calculations are controlled every year at the periodical inspection. Most larger plants are also calibrating other instruments in there own interest or as a consequence of an internal control program.
Notes	Combined heat and power are used as base primarly during the winter half, when the need for heat and power are the largest.
