Technical system description	This dataset represents a model of the cradle to gate production of natural gas. The following process are covered: - Production - Distribution The natural gas is assumed to come from 5 different sources. 52 % from Western Europe, 48 % import - mainly from Russia and Algeria. Medium transport length in Western Europe is 400 km. The transport from Russia and Algeria is a medium value of 690 km in tanks and 1000 km in pipeline. Distribution loss is 0,9 %, and about 0,15 % is flared off under production. 10 % of what is flared stays unburned. Total losses of natural gas about 11 g per kg delivered natural gas. According to the method document in the study, the averages are based on the weight if natural gas from different countries and sources. The study is conducted according to ISO 14040-44, international standards for life cycle assessment. The study agrees well with other studies and databases, but the emissions of nitrous oxide is lower in this study than in others (this does not however affect the results significantly). In general, there is a higher leakage from production and distribution of Russian natural gas, which impacts the total environmental impact if the natural gas mix strongly.

System Boundaries

Nature Boundary	
Time Boundary	2010 - 2013
Geographical Boundary	Western Europe
Other Boundaries	
Allocations	Unknown allocation when natural gas and oil are co-produced.
Systems Expansions	No.

Flow Data

General Activity QMetaData

Date Conceived	
Data Type	
Represents	The data for mounting profile has been approximated with the production of trapezium sheet steel.
Method	Literature studies
Literature Reference	(1) Bousted, Ian (2005). Eco-profiles of the European Plastics Industry – Natural gas, http://lca.plasticseurope.org/ngas3.htm. Production data are from IEA 2001 (2) Swedegas, http://www.swedegas.se/gasnatet/gaskvalitet/gaskvalitet_i_sverige. Here an Exce
Notes	The parameters presented are chosen because they are available in the annual environmental report of the plant. Data can be missing if it is not reported in the report. The type of data reported is governed by the inspection authority. All values are reported with 3 figures. The data are however seldom that accurate.

About Inventory

Publication	Hallberg et al, (2013) "Setup of f3 data network for Well-to-wheel (method and) LCI data for fossil and renewable fuels in the Swedish market", f3 - Swedish Knowledge Centre for Renewable Transportation Fuels, f3 project report, Available at www.f3centre.se
Intended User	LCA practitioner
General Purpose	To provide and publish best available LCI data on vehicle biofuels and fossil fuels well to tank and tank to wheel relevant for the Swedish market.
Detailed Purpose	
Commissioner	- f3 - The Swedish Knowledge Centre for Renewable Transportation Fuels.
Practitioner	- Lisa Bolin (SP), Frida Røyn (SP).
Reviewer	- Lisa Hallberg, IVL

Applicability	
About Data	This dataset is the part of the results from the f3 project "Setup of f3 data network for Well-to-wheel (Method and) LCI data for fossil and renewable fuels in the Swedish market". Further details about this project can be found in the project report.
Notes	

SPINE LCI dataset: Netherlands, electricity generation mix 1998

Administrative	
Finished	Y
Date Completed	2001-01-31
Copyright	IEA
Availability	Public

Technical System	
Name	Netherlands, electricity generation mix 1998
Functional Unit	Total electricity produced during 1998
Functional Unit Explanation	The electricity mix refer to the total amount of electricity generated by different power sources expressed in GWh during the year 1998.
Process Type	Unit operation
Site	Netherlands
Sector	Energyware
Owner	Netherlands
Technical system description	The generation of electricity with different power generating systems in the Netherlands during the year 1998.

System Boundaries	
Nature Boundary	Not applicable, since the data only refer to the electricity generation mix. The environmental load for generation of electricity is not included.
Time Boundary	The data refer to 1998.
Geographical Boundary	Only electricity produced in Australia is considered. Import or export of electricity is not included.
Other Boundaries	-
Allocations	Not applicable
Systems Expansions	Not applicable

Flow Data	
General Activity QMetaData	
Date Conceived	1998
Data Type	Derived, statistics
Represents	The data for mounting profile has been approximated with the production of trapezium sheet steel.
Method	The data are collected from IEA Statistics.
Literature Reference	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8, page II.300.

Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

About Inventory

Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998

	Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998

Technical System	
Name	N-fertilizer production
Functional Unit	kg N
Functional Unit Explanation	Per kg N-fertilizer
Process Type	Gate to gate
Site	Sweden
Sector	Materials and components
Owner	Sweden
Technical system description	Industrial production of N-fertilizer via steam reforming/partial oxidation of fossil fuels and ammonia synthesis through the Haber-Bosch process.

System Boundaries	
Nature Boundary	Emissions to air and water
Time Boundary	Data from 1987-1995
Geographical Boundary	Production site in Germany
Other Boundaries	N/A
Allocations	N/A
Systems Expansions	N/A

Flow Data	
General Activity QMetaData	
Date Conceived	1996-11-14
Data Type	Unspecified
Represents	The data for mounting profile has been approximated with the production of trapezium sheet steel.
Method	These data are weighted averages for different N-fertilizers and are accumulated including ammonia synthesis from fossil fuels, salpete acid production and urea production. Rawmaterials (fuel oil, natural gas, coal and electricity) are registred as energy demands in MJ, and must be connected with the proper energy carrier production activity. Energy for transports is not included.

SPINE LCI dataset: Night vision camera assembly. Autoliv ESA-DBP

Administrative	
Finished	Y
Date Completed	2010-07-15
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Night vision camera assembly. Autoliv ESA-DBP
Functional Unit	1 unit of night vision camera
Functional Unit Explanation	The night vision camera weighs 375 grams
Process Type	Unit operation
Site	Autoliv Goleta. California, United States.
Sector	Manufacturing
Owner	Autoliv Goleta. California, United States.
Technical system description	The studied night vision camera is produced by Autoliv and mounted in BMW and Audi. It is based on far-infrared technology. The device is sensitive to the infrated energy from the warm objects and living beings, which can be seen on the screen by the driver allowing him/her to see in total darkness. The driver can see even 3 times further than the ordinary headlight range. The night vision camera is assembled in Autoliv in Goleta, US. The assembly is done partially manually and with the usage of the special equipment. It weighs 375 grams and consists of few main parts: window retainer, window, lens heater, rubber seal, screws, front enclosure, gasket, lens assembly, shutter, sensor retainer, sensor, heat sink, EMI gasket, video printed circuit board, power printed circuit board, rear enclosure, label and rear

	flange. This process is included in the system described in: Kuvalekar S., Hussain M. (2010). Life cycle assessment of Autoliv's night vision camera. Master thesis report. ESA report 2010:7, ISSN: 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2010--7.pdf Other processes in the CPM Database also included in the above publication: - Night vision camera's rear enclosure manufacturing. Autoliv ESA-DBP - Night vision camera's label manufacturing. Autoliv ESA-DBP - Night vision camera's lens assembly. Autoliv ESA-DBP - Night vision camera's shutter manufacturing. Autoliv ESA-DBP - Night vision camera's spring extension. Autoliv ESA-DBP - Night vision camera's motor manufacturing. Autoliv ESA-DBP - Night vision camera's lens heater manufacturing. Autoliv ESA-DBP - Night vision camera's thermistor manufacturing. Autoliv ESA-DBP - Night vision camera's gasket manufacturing. Autoliv ESA-DBP - Night vision camera's screw manufacturing. Autoliv ESA-DBP - Night vision camera's sensor retainer manufacturing. Autoliv ESA-DBP

System Boundaries

Nature Boundary	The performed study is a unit operation. It relates only to the assembly process of 21 subcomponents. Data given by Autoliv in Goleta, US show the emissions to air and also the waste are produced.
Time Boundary	The data were acquired in 2010 and they come from 2008 and 2009.
Geographical Boundary	The manufacturing plant is located in Goleta, US.
Other Boundaries	Excerpt from the report, see 'Literature reference': ''From feasibility point of view capital goods production and transport, other aspects of environmental related to personnel will not be included in the study. Study does not handle issues related to working environment.''
Allocations	The allocation procedure was applicable in case of electricity, He and CO2. Those values were given for the annual production. Allocation was based on the number of products that were produced.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	2009
Data Type	Derived, unspecified
Represents	See 'Function'
Method	Data gathered from manufacturer using data collection sheet.
Literature Reference	Kuvalekar S., Hussain M. (2010). Life cycle assessment of Autoliv's night vision camera. Master thesis report. ESA report 2010:7, ISSN: 1404-8167. Publication	Kuvalekar S., Hussain M. (2010). Life cycle assessment of Autoliv's night vision camera. Master thesis report. ESA report 2010:7, ISSN: 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2010--7.pdf
Intended User	LCA practitioner
General Purpose	Autoliv has decided to perform 4 LCA projects for the following products: airbag, seatbelt, night vision camera (NVC) and electronic control unit (ECU). The main purpose was to learn more about the products and their environmental performances and eventually decrease their impact on the environment.
Detailed Purpose	The discussed night vision camera was the object of the study. The main goals of the study are: (excerpt from the report, see 'Literature reference') ''1. What are the environmental impacts associated with a night vision camera? 2. What is the amount of waste, energy, water and emissions involved in the whole life cycle of the night vision camera? 3. Are there any materials that need to be replaced in the camera for environmental reasons? 4. To investigate for environmental reasons what would happen in the future if the electronic material is increased in the car?''

Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above

About Data	ESA database project. Year 2010. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: the Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	The product is quite new on the market. The first version appeared in 2005 and from 2008 2nd model of night vision camera is available. At the end of its life, night vision camera as a part of the car is shredded together with it. According to Stena Metal AB 99% of metal parts is recycled. Plastic parts are recovered as an energy. Not all the parts can be recovered. The window for example, which consists of germanium, is landfilled. The studied product is a part of the night vision camera which was the object of the LCA study for Autoliv. More processes from the same study were also documented in this database. In parallel to the night vision camera, 3 other LCA studies for Autoliv were carried out (for airbag, seatbelt and electronic control unit). Some of the processes can be found also in the CPM database.

SPINE LCI dataset: Night vision camera's gasket manufacturing. Autoliv ESA-DBP

Technical System	
Name	Night vision camera's gasket manufacturing. Autoliv ESA-DBP
Functional Unit	1 gasket
Functional Unit Explanation	1 gasket weighs 1 gram. There are three different parts in a night vision camera. The night vision camera weighs 375 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	A gasket is used ussually to fill the space between two or more objects in order to for example keep the gas or liquid pressure or insulating the object from the air, moisture or other liquids. There are few gaskets in the night vision camera: by front enclosure, rear enclosure and window. The content, weight, production processes and manufacturer are the same for all of them. They are made of rubber EPDM (ethylene propylene diene monomer) and carbon black. The weight is 1 gram. They are manufactured in Chicago, US. The production process consists of the following steps: 1. Heating and moulding the rubber 2. Adding the silicon as a inner core material 3. Adding carbon black This process is included in the system described in: Kuvalekar S., Hussain M. (2010). Life cycle assessment of Autoliv's night vision camera. Master thesis report. ESA report 2010:7, ISSN: 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2010--7.pdf Other processes in the CPM Database also included in the above publication:

	- Night vision camera assembly. Autoliv ESA-DBP - Night vision camera's rear enclosure manufacturing. Autoliv ESA-DBP - Night vision camera's label manufacturing. Autoliv ESA-DBP - Night vision camera's lens assembly. Autoliv ESA-DBP - Night vision camera's shutter assembly. Autoliv ESA-DBP - Night vision camera's spring extension. Autoliv ESA-DBP - Night vision camera's motor manufacturing. Autoliv ESA-DBP - Night vision camera's lens heater manufacturing. Autoliv ESA-DBP - Night vision camera's thermistor manufacturing. Autoliv ESA-DBP - Night vision camera's screw manufacturing. Autoliv ESA-DBP - Night vision camera's sensor retainer manufacturing. Autoliv ESA-DBP

System Boundaries

Nature Boundary	The performed study is gate-to-gate. It starts with processing the materials from the suppliers and ends with adding carbon black. Data given by gasket manufacturer do not show any emissions.
Time Boundary	The data were acquired in 2009.
Geographical Boundary	The manufacturer is placed in Chicago in Illinois, US.
Other Boundaries	Excerpt from the report, see 'Literature reference': ''Maintenance of production capital as well as personnel related environmental impacts were excluded from the study. Transportation within the production plant was not included.''
Allocations	The data were given per month. The allocation was done based on the number of produced products.
Systems Expansions	Not applicable

Technical System	
Name	Night vision camera's label manufacturing. Autoliv ESA-DBP
Functional Unit	1 label
Functional Unit Explanation	1 label weighs 0.5 gram and it is a part of night vision camera which weighs 375 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	The label has an informing function. The studied one is manufactured in Strongsville in Ohio, US. The label is blank and it is processed later in Autoliv. The label consists of silicon coated paper, adhesive and a film which is made from PET (Polyethylene terephthalate) and it weighs 0.5 gram. The materials are produced 100 miles from the plant in Strongsville.

	Manufacturing process of label consists of the following steps: 1. Applying adhesive into 1 side of PET film. 2. Laying the liner on the other side This process is included in the system described in: Kuvalekar S., Hussain M. (2010). Life cycle assessment of Autoliv's night vision camera. Master thesis report. ESA report 2010:7, ISSN: 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Technical System	
Name	Night vision camera's lens assembly. Autoliv ESA-DBP
Functional Unit	1 lens assembly
Functional Unit Explanation	1 lens assembly weighs 4.6 grams and it is a part of the night vision camera which weighs 375 grams.

Process Type	Unit operation
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	Lenses in the cameras are ussualy made of one or few layers of transparent material (can be glass, plastics, gel etc.). The basic function of them is focusing or diffusing the light in order to achieve a better picture. (Wikipedia, 2010). In case of night vision camera there are two different layers: germanium and zinc-selenium. Except those in the lens assembly there are many other parts like: housing, spacer, lens cell, flange, retaining ring, sleeve cast, retaining nut, bushing, wave spring, wave spring washer, self lock, bushing 7.8 mm and bushing 8.9 mm. In total it weighs 4.6 grams. This process is included in the system described in: Kuvalekar S., Hussain M. (2010). Life cycle assessment of Autoliv's night vision camera. Master thesis report. ESA report 2010:7, ISSN: 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. System Boundaries

Nature Boundary	The performed study is a unit operation. It relates to the assembly process of the lens. Data given by lens manufacturer show air emissions. Liquid and solid waste is produced.
Time Boundary	The data were acquired in 2009 and 2010.
Geographical Boundary	The lens manufacturer is located in North Andover in Massachusetts, US.
Other Boundaries	Excerpt from the report, see 'Literature reference': ''Maintenance of production capital as well as personnel related environmental impacts were excluded from the study. Transportation within the production plant was not included.''
Allocations	Allocation for electricity, waste and emissions was done based on monthly values of these items and annual production. The values were calculated for 1 year and divided in a number of produced lenses.
Systems Expansions	Not applicable

Technical System	
Name	Night vision camera's lens heater manufacturing. Autoliv ESA-DBP
Functional Unit	1 lens heater
Functional Unit Explanation	1 lens heater weighs 0.2 gram while the whole night vision camera weighs 375 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	The lens heater is a part which has a function of eliminating the moisture from inner part of the camera especially on the surface of the lens. The heater is manufactured in Kolbäck, Sweden. It consists of copper nickel foil, polyamide 66, adhesive, poron and thermistor and weighs 0.2 gram. The production process consists of the following steps: 1. Creating a metal circuit using CuNi foil 2. Laminating with thick polyamide film 3. Printing the pattern circuit on metal side with UV cured paint 4. Etching with iron chloride the non covered areas 5. Putting the top lamination 5. Soldering the thermistor 6. Adding the poron layer 7. Shaping 8. Control This process is included in the system described in: Kuvalekar S., Hussain M. (2010). Life cycle assessment of Autoliv's night vision camera. Master thesis report. ESA report 2010:7, ISSN: 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. About Inventory

Publication	Kuvalekar S., Hussain M. (2010). Life cycle assessment of Autoliv's night vision camera. Master thesis report. ESA report 2010:7, ISSN: 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2010--7.pdf
Intended User	LCA practitioner

General Purpose	Autoliv has decided to perform 4 LCA projects for the following products: airbag, seatbelt, night vision camera (NVC) and electronic control unit (ECU). The main purpose was to learn more about the products and their environmental performances and eventually decrease their impact on the environment.
Detailed Purpose	The discussed lens heater is a part of the night vision camera which was the object of the study. The main goals of the study are (excerpt from the report, see 'Literature reference'): ''1. What are the environmental impacts associated with a night vision camera? 2. What is the amount of waste, energy, water and emissions involved in the whole life cycle of the night vision camera? 3. Are there any materials that need to be replaced in the camera for environmental reasons? 4. To investigate for environmental reasons what would happen in the future if the electronic material is increased in the car?''
Commissioner	Autoliv Development AB - .
Practitioner	Shweta Kuvalekar & Munnwer Hussain - .
Reviewer	Birgit Brunklaus & Henrikke Baumann -
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Year 2010. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: the Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	In the study it was assumed that the camera is dismantled by the personnel in recycling company and 95% of metal parts are recycled. The rest is landfilled. In case of plastics 5% is incinerated, 10% goes to the landfill and the rest is recycled (apart from germanium which is landfilled). The studied product is a part of the night vision camera which was the object of the LCA study for Autoliv. More processes from the same study were also documented in this database. In parallel to the night vision camera, 3 other LCA studies for Autoliv were carried out (for airbag, seatbelt and electronic control unit). Some of the processes can be found also in the CPM database.

SPINE LCI dataset: Night vision camera's motor manufacturing. Autoliv ESA-DBP

Technical System	
Name	Night vision camera's motor manufacturing. Autoliv ESA-DBP
Functional Unit	1 motor
Functional Unit Explanation	1 motor weighs 2.8 grams while the whole night vision camera weighs 375 grams.
Process Type	Unit operation
Site	Unknown
Sector	Manufacturing
Owner	Unknown

Technical system description	Motor is a part of a shutter in the night vision camera. It is produced in Hongkong. It consists of the folloing parts: washer, shaft, core, insulating material, commutator core, commutator, commutator washer, rotor bush, varistor, solder, magnet wire, plastic magnet, housing, bearing, terminal, brush, bearing, endbell, adhesive and grease. In general the studied motor consists of 50 % of steel, 25% of copper and 25% of polymer. The total weight of motor is 2.8 grams. This process is included in the system described in: Kuvalekar S., Hussain M. (2010). Life cycle assessment of Autoliv's night vision camera. Master thesis report. ESA report 2010:7, ISSN: 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2010--7.pdf Other processes in the CPM Database also included in the above publication: - Night vision camera assembly. Autoliv ESA-DBP - Night vision camera's rear enclosure manufacturing. Autoliv ESA-DBP - Night vision camera's label manufacturing. Autoliv ESA-DBP - Night vision camera's lens assembly. Autoliv ESA-DBP - Night vision camera's shutter assembly. Autoliv ESA-DBP - Night vision camera's spring extension. Autoliv ESA-DBP - Night vision camera's lens heater manufacturing. System Boundaries

Nature Boundary	The performed study is a unit operation. It relates to the assembly process of the components. Data given by motor manufacturer show waste and air emissions.
Time Boundary	The data were acquired in 2009.
Geographical Boundary	The manufacturing plant is located in Hong Kong.
Other Boundaries	Excerpt from the report, see 'Literature reference': ''Maintenance of production capital as well as personnel related environmental impacts were excluded from the study. Transportation within the production plant was not included.''
Allocations	The data were given per 1 motor by the manufacturer.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	2009
Data Type	Derived, unspecified
Represents	See 'Function'
Method	Data gathered from manufacturer using data collection sheet.
Literature Reference	Kuvalekar S., Hussain M. (2010). Life cycle assessment of Autoliv's night vision camera. Master thesis report. ESA report 2010:7, ISSN: 1404-8167. Technical System	
Name	Night vision camera’s rear enclosure manufacturing. Autoliv ESA-DBP
Functional Unit	1 unit of rear enclosure
Functional Unit Explanation	1 rear enclosure weighs 107 grams and it is a part of night vision camera which weighs 375 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	A rear enclosure part has a housing function for the camera. It is located on the back side of the it and is responsible for keeping the rear parts together. It is made of alluminium alloy and weighs 107 grams. The rear enclosure is produced in the plant in Lake Forest City in California. The manufacturing process consists of the following steps: 1. Dye casting 2. Removing the debris 3. Finishing on CNC machine This process is included in the system described in: Kuvalekar S., Hussain M. (2010). Life cycle assessment of Autoliv’s night vision camera. Master thesis report. ESA report 2010:7, ISSN: 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Intended User	LCA practitioner
General Purpose	Autoliv has decided to perform 4 LCA projects for the following products: airbag, seatbelt, night vision camera (NVC) and electronic control unit (ECU). The main purpose was to learn more about the products and their environmental performances and eventually decrease their impact on the environment.
Detailed Purpose	The discussed sensor retainer is a part of the night vision camera which was the object of the study. The main goals of the study are (excerpt from the report, see 'Literature reference'): ''1. What are the environmental impacts associated with a night vision camera? 2. What is the amount of waste, energy, water and emissions involved in the whole life cycle of the night vision camera? 3. Are there any materials that need to be replaced in the camera for environmental reasons? 4. To investigate for environmental reasons what would happen in the future if the electronic material is increased in the car?''

Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Year 2010. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: the Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	In the study it was assumed that the camera is dismantled by the personnel in recycling company and 95% of metal parts are recycled. The rest is landfilled. In case of plastics 5% is incinerated, 10% goes to the landfill and the rest is recycled (apart from germanium which is landfilled). The studied product is a part of the night vision camera which was the object of the LCA study for Autoliv. More processes from the same study were also documented in this database. In parallel to the night vision camera, 3 other LCA studies for Autoliv were carried out (for airbag, seatbelt and electronic control unit). Some of the processes can be found also in the CPM database.

SPINE LCI dataset: Night vision camera's shutter assembly. Autoliv ESA-DBP

Administrative	
Finished	Y
Date Completed	2010-07-15
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology

Technical System	
Name	Night vision camera's shutter assembly. Autoliv ESA-DBP
Functional Unit	1 shutter
Functional Unit Explanation	1 shutter weighs 5.15 grams and it is a part of the night vision camera which weighs 375 grams.

Process Type	Unit operation
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	In general a shutter is a component of a camera which is opened and closed in order to allow the light to pass through the lens to the light sensitive electronic sensor. (Wikipedia, 2010). In the night vision camera it allows to register and view clear image even of the fast moving objects. (Media College, 2010) The studied shutter is produced in a plant in Mexico and then transported to Autoliv Goleta in US. It consists of few components: paddle, spring, spring clip, pinion gear, face gear, gearbox cover, harness, and motor. Most of the components is assembled using the adhesive. The weight of the shutter is 5.15 grams. This process is included in the system described in: Kuvalekar S., Hussain M. (2010). Life cycle assessment of Autoliv's night vision camera. Master thesis report. ESA report 2010:7. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2010--7.pdf Other processes in the CPM Database also included in the above publication: - Night vision camera assembly. Autoliv ESA-DBP - Night vision camera's rear enclosure manufacturing. Autoliv ESA-DBP - Night vision camera's label manufacturing. Autoliv ESA-DBP - Night vision camera's lens assembly. Autoliv ESA-DBP - Night vision camera's spring extension. Autoliv ESA-DBP - Night vision camera's motor manufacturing. Autoliv ESA-DBP - Night vision camera's lens heater manufacturing. Autoliv ESA-DBP - Night vision camera's thermistor manufacturing. Autoliv ESA-DBP - Night vision camera's gasket manufacturing. Autoliv ESA-DBP - Night vision camera's screw manufacturing. Autoliv ESA-DBP - Night vision camera's sensor retainer manufacturing. Autoliv ESA-DBP NB: Reference: Media College, 2010 (online) Available at: http://www.mediacollege.com/video/camera/shutter/ [accessed 30.06.2010] Wikipedia.2010 (online) Available at: http://en.wikipedia.org/wiki/Shutter_(photography) [accessed 30.06.2010]

System Boundaries

Nature Boundary	The performed study is a unit operation. It relates to the assembly process of shutter. Data given by the shutter manufacturer show only air emissions and waste production.
Time Boundary	Data were acquired in 2009.
Geographical Boundary	The shutter manufacturer is located in Mexico.
Other Boundaries	Excerpt from the report, see 'Literature reference': ''Maintenance of production capital as well as personnel related environmental impacts were excluded from the study. Transportation within the production plant was not included.''
Allocations	Most of the data was given per month except suspended solids and VOC which were given my year. The allocation was based on the annual and monthly number of produced items.
Systems Expansions	Not applicable

SPINE LCI dataset: Night vision camera's thermistor manufacturing. Autoliv ESA-DBP

Administrative	
Finished	Y
Date Completed	2010-07-15
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Night vision camera's thermistor manufacturing. Autoliv ESA-DBP
Functional Unit	1 thermistor
Functional Unit Explanation	1 thermistor weighs 0.0047 gram.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	Thermistor is a type of resistor whose resistance depends on the temperature. It is widely used in the electronic devices. (Thermometrics, 2010) The studied thermistor is placed in a lens heater. It is made of metal and ceramic and it weighs 0.0047 gram. The manufacturer of it is located in Nagaokaky, Japan. The manufacturing process consists of the following steps: 1. Sheet making 2. Inner electrode printing 3. Sheet stacking 4. Stacked block cutting to make a green thermistor chip 5. Termination 6. Plating 7. Inspection This process is included in the system described in: Kuvalekar S., Hussain M. (2010). Life cycle assessment of Autoliv's night vision camera. Master thesis report. ESA report 2010:7, ISSN: 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. About Inventory

Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.

Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998

Technical System	
Name	Nuclear electricity energy system, EPD-version
Functional Unit	1 TJ net electricity from power plant
Functional Unit Explanation	The generation of 1 TJ (1 000 000 000 000 J) net electricity (i.e. electricity need in the power plant has been supplied for by the plant itself). Electricity distribution and distribution losses are not accounted for, i.e. not for this particular unit process. Data about distribution and its losses may however be found in the original study.
Process Type	Cradle to grave
Site	UCTPE countries Europe
Sector	Grid electricity and district heat
Owner	UCTPE countries Europe
Technical system description	Reported figures are based on data from a LCI-study performed at ETH, Zürich and Paul Scherrer Institut, Villigen, ''Ökoinventare von Energiesystemen'', 3rd edition 1996 and adapted to the demands of the EPD-guidelines (Environmental Product Declaration guidelines in Sweden). -- Brief description -- The phases inventoried in ETH's life cycle study of nuclear power are: uranium mine, uranium ore processing, conversion, enrichment, fuel fabrication, nuclear power plant, reprocessing of spent fuel, interim and final storages for conditioned low, medium and high level radioactive waste. Data has been aquired from literature and figures concerning consumption of energyware and materials, use of land and water, emissions (radioactive and non-radioactive to air and water) and wastes have been picked out from or calculated based on literature and official reports from authorities where available for all phases of the life cycle. All subsystems are described on a ''cradle-to-grave'' basis, including the main stages, i.e. data concerning consumption of resources, waste handling and emissions is included for the manufacturing of main materials and energyware used in the lifecycle. -- Detailed description -- Uranium mine Underground and open pit mining has been studied including extraction work, transports, water pumping, ventilation (underground mining) and restoration of mines (only land use). Uranium concentration in studied mines varies between 0.1-15% U3O8 in open pit mines, average 1,3%. The average U3O8 concentration in underground mines is 1,7%. 1 kg uranium in ore in this study is assumed to contain 0,6 kg from open pit mines and 0,4 kg from underground mines. Uranium ore processing Uranium ore processing implying crushing, grinding, chemical processing (oxidation, leaching), metal extraction (ion-exchange), waste treatment and final treatment to receive the product - yellow cake - has been included, also with respect to longliving radioactive emissions of tailings. Construction phase of plant is included. Conversion Conversion (wet concept, UNH) of virgin U3O8 to UF6 is included, implying dissolvation of ''yellow cake'' (U3O8) in nitric acid, purification through solvent extraction, conversion to uranylnitrathexahydrate (UNH), denitrification to UO3, reduction to UO2, conversion to UF4 with hydrofluoric acid and reaction with fluor gas to UF6. Process efficiency is high (>99.8%). Construction phase and solid wastes in connection with demolition of plant is included. Enrichment Enrichment of virgin UF6 from a U235 content of about 0.7% to a content of 3-4% is included. Two methods have been inventoried: - gaseous diffusion UF6 is passed through a fine porous filter and U235 being slightly lighter than U238 moves faster which lead to a slightly higher concentration of U235 on the other side of the filter. The process must be repeated 1,200 times to yield the a concentration of 3% U235 and is very energyware intensive. - gas centrifugation The isotope U238 is heavier than U235 and the centrifugal forces will tend to separate the two by pressing U238 to the outer wall of the centrifuge while U235 stays closer to the axis. The process must be repeated many times, but the energyware consumption is still about ten times lower than for the diffusion process.

	Electricity consumed during enrichment using gaseous diffusion is generated with a nuclear power plant and a hard coal power plant for the French and the US-American enrichment plant, respectively. Consumption of chemicals and materials, other energyware and water as well as radionuclide emissions are other factors considered in the operation phase of the enrichment plants. The different nuclear power nations purchase of nuclear fuel enriched with either method has been taken into account. 77% of nuclear fuel used in the UCPTE* countries is assumed to have been enriched with the diffusion process (83% in France and 17% in USA) and 23% with the centrifugal process (74% in UK and 6% in Russia). Data concerning this distribution has been calculated based on figures from literature and on the main suppliers' market share. Construction phase of enrichment plants is included as well as energyware consumption and solid wastes during the demolition phase. Fuel fabrication Fuel fabrication of virgin uranium is included: solid UF6 is heated into gaseous state, conversion into uranium dioxide powder, compression into cylindrical pellets, sintering and grinding, pellets are placed in zircaloy (zirconium alloy) tubes, tubes are pressurized with helium and sealed to form fuel rods, rods are bundled into fuel assemblies. Literature data mainly from two plants - one in Germany and one in USA - have been used. Construction of plant is included as well as demolition. Nuclear power plant Two Swiss light water nuclear power plants have been inventoried with respect to construction, operation and demolition - one BWR (Boiling Water Reactor) and one PWR (Pressurized Water Reactor), both about 1000 MW e and 25500 TJ net electricity production per year. Data about construction and demolition has been adapted to UCPTE conditions (90% PWR and 10 % BWR). Country specific radionuclide emissions are applied for French, German and Swiss nuclear power plants. Test operation of diesel-fuelled reserve power is included. Reprocessing Though severel of the UCPTE* nuclear power nations do not use reprocessed fuel, all spent fuel is supposed to be reprocessed in ETH's study. UO2 pellets are dissolved in nitric acid and uranium and plutonium is regained. Construction, operation and demolition has been included. Interim storage Before and after reprocessing interim storages are needed for spent uranium fuel and radioactive wastes from the reprocessing plant respectively. The studied interim storage will store high, medium and low level radioactive products. The plant also includes a treatment plant for low level radioactive wastes (incineration and conditioning). Construction, operation and demolition of the plant are included. Final storage Two types of final storages have been included in the study, one for low and medium level radioactive wastes in horizontal caverns and one storage for high radioactive waste in vertical shafts deep in the mountain. Studied concepts are not built yet. Encapsulation is included. Construction, operation and sealing of the storages are included. Radionuclide emissions to groundwater are not included. Transports Transports of the interim products in the nuclear fuel chain between all plants have been included as well as transports of materials, chemicals and wastes. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.

System Boundaries	
Nature Boundary	Used materials and energyware have been followed from extraction and processing of natural resources. Maufacturing processes for the use of recycled material are accounted for. Emissions from energyware use in manufacturing processes and transports (infrastructure and vehicle construction included) are considered as well as emissions from landfills (infrastructure included) where waste material is disposed of. Waste material supposed to be recycled are outputs of the system (i.e. those recycling processes are not included). ETH's LCI-results comprise all parameters received during inventory and calculation, i.e. no selection has been made by ETH. Vattenfall's criterion in selecting and aggregating ETH's LCI-results for electricity generation in the UCPTE region has been to make the figures usable as general electricity LCI data in EPDs according to Miljöstyrningsrådets guidelines. Especially parameters (emissions) which have established impact indices - accepted by the EPD system - for one or several environmental impact categories, have been picked out and aggregated as far possible. But also metal and energyware resources have been included, as well as waste, in spite of all waste handling processes related to this dataset being

	included with respect to use of resources and emissions. The latter is an adaption to other LCI data for electricity generation where waste amounts are reported (since those flows have not been followed to the grave). Since ETH claimes that most of the figures regarding metal emissions have an undefined amount of datagaps all metal emissions are aggregated except for a few which are specified separatly since they are reported for most processes in the lifecycle. Metals are reported as elements although they often are part of compounds. Measuring methods often just give the amounts of the different elements found. All hydrocarbons to water are aggregated to one parameter as well as halogenated organics, since no indices exist (that are accepted by the EPD system so far) for characterisation of the individual substances.
Time Boundary	The figures describe the average operation of studied plants in 1994. But for radioactive emissions figures mirrors the period from 1992-1994. Different technical lifetimes/reference times for different parts and materials of the studied systems have been used as follows: Conversion plant 40 years Enrichment plants 30 years Fuel fabriction 30 years Nuclear power plants 40 years Reprocessing plant 30-40 years * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Geographical Boundary	Only the following countries in the UCPTE* do have nuclear power: Germany, Belgium, France, The Netherlands, Switzerland, Slowenia and Spain. Data from one open-pit mine in Canada and two underground mines in the USA have been used as well as general literature data. Data for the uranium ore processing phase come from literature, one plant in Canada and two plants in the USA. Literature data describing American conversion plants have been used. Examined enrichment plants (literature data) are: EURODIF in France and USEC in the USA (gaseous diffusion); URENCO in Germany, UK and the Netherlands, and TENEX in Russia (gas centrifugation). Two Swiss nuclear power plants have been studied in detail concerning their actual fuel chain and their operation. Data received from the Swiss plants has been adapted to the average situation in the UCPTE* region in 1994 with the help of certain specific data from France and Germany. Data about radioactive emissions of nuclear power plants have been received from statistics in Switzerland, France and Germany. Figures from the most modern reprocessing plant in Sellafield, UK (THORP) and a prospected plant in Germany for spent uranium fuel have been used in the study together with other literature data. Studied storage concepts (interim and final) are Swiss. Data concerning the use of resources, emissions and waste in connection with manufacturing processes mainly originate from sources in Switzerland, Germany and other western European countries. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Other Boundaries	The restoration of uranium mines is not included in ETH's study except for land use. Demolition phase of uranium ore processing plant is excluded as well as environmental load on ground and ground water. Material need and energyware consumption in the demolition phase of conversion plant is not included, nor is treatment of operational solid waste. Regaining of hydrofluoric acid in the enrichment phase and the use of depleted UF_6 for further extraction of UO_2 has not been considered. Depleted UF_6 is neither considered as waste. Material need in the operation phase of diffusion plants and in the demolition phase of both kind of enrichment plants has been excluded. Diffusion process in France is supplied by nuclear power, and in USA by coal power. British and Russian centrifugal plants are supplied with UCPTE* electricity (mix of several power systems representativ for the actual situation in the UCPTE region).

	For the fuel fabrication plants data about some chemical use is missing and emissions during the demolition phase are not complete. Emissions to air and water in the demolition phase of nuclear power plant is not included. The reuse of extracted uranium and plutonium from spent fuel in nuclear power plant operation has not been taken into account. Manufacturing processes of components and machines have been approximated with 50% of the energyware used to produce contained materials. Energyware figures concerning material production come from literature and have assumed to be a mix of 10% UCPTE electricity, 45% oil and 45% natural gas. This approximation has been confirmed in more thorough calculations in ETH:s LCA for coal power. The ETH study comprises figures concerning use of land, usable content in water storages and amount of turbine water which have not been reported here. The two latter have been excluded due to lack of corresponding data in comparable studies. Use of land has been excluded here because of ETH's advanced approach. Land is divided into two main groups - land and sea - which are subdivided into 4 categories each. Land Criterion Category Natural human impact not larger than other species' since the indutrial revolution I Modified human impact larger than other species', low degree of culivation II Cultivated human impact larger than other species', large degree of cultivation III Built upon dominated by buildings, roads, dams, mines etc. IV Category I is not used in the study. State of land before, during and after exploitation is of intererst. If a piece of land is used again after some kind of exploitation it will either end up in the same category or in a higher one. ETH takes into account not only the land used during the technical lifetime of the studied system but also during the construction phase and during the time it takes to restore the land. They express use of land in the unit m2year which is diffrent from comparable Swedish studies (m2). See times for restoration of land below: From category IV to category III 5 years From category III to category II 50 years From category II to category I 100 000 years For uranium mines the restoration time to category II is 80'000 years due to elevated radiation caused by long-living radioactive compounds. ETH specifies about 160 radioactive isotopes emitted to air and water. Radioactive emissions reported here are picked out in accordance with SETAC working group report on data quality and data availability (to be published in 2001). Big accidents occuring seldomly are not included.The threshold is fixed at 10 accidents per year if one energy carrier/system (e.g. oil) would cover the entire primary energy demand of the world.
Allocations	Inventoried data from different literature references has been put together to form indata to the calculated modules within the nuclear fuel cycle: uranium mine, uranium ore processing, conversion, enrichment, fuel fabrication, nuclear power plant, reprocessing, interim storage and final storages for conditioned low, medium and high level radioactive waste. Criterias for chosing certain data is described in the original report from ETH. Criterias are different for different parameters. Allocation in the enrichment phase between different suppliers (diffusion and cetrifugation plants) has been done according to the assumed UCPTE purchase in 1994, i.e. 77% diffusion plants and 23% centrifugal plants. Generally the allocation between different ''stakeholders'' in all steps has been conducted according to the need of uranium and according to the need of uranium disposal. The cutoff-method has been used for material use, i.e. 100% of the environmental load for virgin and recycled material used in the lifecycle is included whereas no environmental load has been considered for materials leaving the system to be recycled. Landfill processes and waste incineration, however, are included for waste arising during the lifecycle.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1985 to 1995
Data Type	Derived, unspecified
Represents	Average nuclear power in the UCPTE countries.
Method	The data has been adapted from the Ökoinventare von Energiesystemen, ETH Zürich 1996 and is an aggregation of the LCI results for the module ''Electricity from nuclear power, UCPTE'' (Strom ab KKW, UCPTE). (KKW=Kernkraftwerk)

Literature Reference	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz, Environmental Life-Cycle Inventories of Energy Systems An Environmental Database for the Accounting of Energy Consumption in Product Life-Cycle Assessment and the Comparative Assessment of Energy systems Prof. Dr. P. Suter, R. Frischknecht, et al Swiss Federal Institute of Technology, Zürich R. Dones, U. Gantner Paul Scherrer Institute, Villigen/Würenlingen
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

About Inventory

Publication	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz. ETH, Eidgenössische Technische Hochschule, Zürich, Gruppe Energie - Stoffe - Umwelt (ESU), Paul Scherrer Institut, Villigen/Würenlingen, Sektion Ganzheitliche Systemanalysen Available on CD-ROM with full documentation (in German) at http://www.energieforschung.ch. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by (see also Notes): Rolf Frishknecht, ESU-services, Switzerland Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	Original study of ETH: LCA pra
General Purpose	The purpose of the ETH study was to examine a number of energy systems quantitatively and to the same extent with respect to environmental issues during their lifecycles. The results can be used in lifecycle assessments, as basis information in decisionmaking regarding environmental optimisation or in working with municipal energy plans. Vattenfalls purpose - as a commissioner of putting ETH:s data into Spine format with metadata - is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines. Data is supposed to be used together with IEA statistics about electricity generation mixes in the OECD countries/regions.
Detailed Purpose	ETH:s aim of this LCI was to describe the averag situation in UCPTE concerning electricity generation with nuclear power. Material and energyware needs, emissions and solid waste have been inventoried in all steps of the nuclear fuel cycle regarding construction, operation and demolition phases all through the lifecycle.
Commissioner	BEW, PSEL - Bundesamt für Energiewirtschaft, Projekt- und Studienfonds der Elektrizitätswirtschaft .
Practitioner	Rolf Frischknecht et al - ETH, Eidgenössische Technische Hochschule, Institut für Energietechnik, Zürich and Paul Scherrer Institut, Sektion Ganzheitliche Systemanalyse, Villingen/Würenlingen .
Reviewer	None, see further under notes -
Applicability	Data reported here is supposed to be representative for nuclear power in the UCPTE countries in 1994. This set of data is aggregated and documented in accordance with the Swedish EPD-guidelines to be used in combination with IEA statistics concerning electricity generation mixes in OECD countries and regions together with other datasets - based on the ETH study - describing other power generation systems. The EPD-adapted power generation systems in Spine format are named as follows: Fuel gas electricity energy system, EPD-version Biofuel electricity energy system, EPD-version Hydro electricity energy system, EPD-version Lignite electricity energy system, EPD-version Nuclear electricity energy system, EPD-version Stone coal electricity energy system, EPD-version Wind electricity energy system, EPD-version IEA statistics for generation mixes 1998 exist in Spine format for the following 30 countries/regions: OECD total OECD North America OECD Pacific OECD Europe European Union Australia Austria Belgium Canada Czech Rpublic Denmark Finland France Germany Greece Hungary Iceland

	Ireland Italy Japan Korea Luxembourg Mexico Netherlands New Zealand Norway Poland Portugal Spain Sweden Switzerland Turkey United Kingdom United States
About Data	The exactitude concerning radioactive emissions to air and water is ±50%. Data concerning construction of UCPTE nuclear power is probably slightly overestimated since a major part of French and German nuclear power plants have a capacity of about 1300 MWe. Material manufacturing processes have been inventoried with a low degree of exactitude (except for steel, cement, aluminium, copper, bitumen, and platinum group metals for which rather detailed LCI data are provided). Results are reported with three figures, but it is stated in the original source that this does not mean that accuracy is that high (Part III, p.16). For references and sources of reported figures see further under Function, Nature boundary, Geographical boundaries, Publication, Notes and General metadata.
Notes	Reviewer of this specification of ETH:s data and metadata has been: Dr. Rolf Frischknecht, ESU-services (earlier at ETH) - approval of aggregation of figures and of Vattenfall's interpretation ot the documentation Ann-Christin Pålsson, CPM - review of documentation quality according to the CPM data documentation requirements. The technical committee of the Swedish Environmental Management Council - approval of method and aggregation of parameters Project Management of the ETH study, 3rd edition: Professor, Dr. P. Suter and R. Frischknecht, ETH Editorial staff of the 1st edition: R. Frischknecht, P. Hofstetter, I. Knoepfel, M. Ménard, ETH R. Dones, E. Zollinger, Paul Scherrer Institut Authors of the 1st edition: N. Attinger, T. Baumann, G. Doka, R. Dones, R. Frischknecht, H.-P. Gränicher, C. Grasser, P. Hofstetter, I. Knoepfel, M. Ménard, H. Müller, M. Vollmer, E. Walder, E. Zollinger Authors of the revision, 3rd edition: U. Bollens, S, Bosshart, M. Ciot, L. Ciseri, G. Doka, R. Frischknecht, R Hischier, A. Martin, ETH R. Dones, U. Gantner, Paul Scherrer Institut --- --- Changes made to the data set after publishing in SPINE@CPM--- >>> 6 June 2001: <<< Changes made by Ann-Christin Pålsson, CPM based on discussions with Caroline Setterwall, Vattenfall AB. Comments: The following changes has been made in the nomenclature for in- and outflows: Mangane in ore -> changed to: Manganese in ore CH4 -> changed to: Methane (to be in accordance with the nomenclature specified in CPM report 2000:2) CN -> changed to: CN- Stone coal -> changed to: Hard coal (to be in accordance with the nomenclature specified in CPM report 2000:2) Other metals -> changed to: Metals Explanations of nomenclature (inserted in Notes for the specific flows): - CN- is Cyanide ion - Reactive waste deposit is waste at landfill that is still reactive. - Inert waste deposit is waste at landfill that are inert. Additional clarifications: - Note that the flows of waste in the table of in- and outflows are internal flows, i.e. they do NOT cross the system boundaries. All waste handling processes is included in the study with respect to use of resources and emissions. - Radioactive waste is accounted for in cubic metres. The product specific requirements for electricity and district heating generation (PSR 1998:1) in the Swedish EPD system states that waste shall be accounted for in gram. However, no conversion factors were given in the study. There are also no general conversion factors that are commonly used.

SPINE LCI dataset: Nuclear electricity energy system, ETH - full version

Technical System	
Name	Nuclear electricity energy system, ETH - full version
Functional Unit	1 TJ net electricity from power plant
Functional Unit Explanation	The generation of 1 TJ (1 000 000 000 000 J) net electricity (i.e. electricity need in the power plant has been supplied for by the plant itself). Electricity distribution and distribution losses are not accounted for, i.e. not for this particular unit process. Data about distribution and its losses may however be found in the original study.
Process Type	Cradle to grave
Site	UCTPE countries Europe
Sector	Grid electricity and district heat
Owner	UCTPE countries Europe
Technical system description	Reported figures come from a LCI-study performed at ETH, Zürich and Paul Scherrer Institut, Villigen, ''Ökoinventare von Energiesystemen'', 3rd edition 1996. Brief description The phases inventoried in ETH's life cycle study of nuclear power are: uranium mine, uranium ore processing, conversion, enrichment, fuel fabrication, nuclear power plant, reprocessing of spent fuel, interim and final storages for conditioned low, medium and high level radioactive waste. Data has been aquired from literature and figures concerning consumption of energyware and materials, use of land and water, emissions (radioactive and non-radioactive to air and water) and wastes have been picked out from or calculated based on literature and official reports from authorities where available for all phases of the life cycle. All subsystems are described on a ''cradle-to-grave'' basis, including the main stages, i.e. data concerning consumption of resources, waste handling and emissions is included for the manufacturing of main materials and energyware used in the lifecycle. Detailed description Uranium mine Underground and open pit mining has been studied including extraction work, transports, water pumping, ventilation (underground mining) and restoration of mines (only land use). Uranium concentration in studied mines varies between 0.1-15% U3O8 in open pit mines, average 1,3%. The average U3O8 concentration in underground mines is 1,7%. 1 kg uranium in ore in this study is assumed to contain 0,6 kg from open pit mines and 0,4 kg from underground mines. Uranium ore processing Uranium ore processing implying crushing, grinding, chemical processing (oxidation, leaching), metal extraction (ion-exchange), waste treatment and final treatment to receive the product - yellow cake - has been included, also with respect to longliving radioactive emissions of tailings. Construction phase of plant is included. Conversion Conversion (wet concept, UNH) of virgin U3O8 to UF6 is included, implying dissolvation of ''yellow cake'' (U3O8) in nitric acid, purification through solvent extraction, conversion to uranylnitrathexahydrate (UNH), denitrification to UO3, reduction to UO2, conversion to UF4 with hydrofluoric acid and reaction with fluor gas to UF6. Process efficiency is high (>99.8%). Construction phase and solid wastes in connection with demolition of plant is included.

Enrichment
Enrichment of virgin UF6 from a U235 content of about 0.7% to a content of 3-4% is included. Two methods have been inventoried:
- gaseous diffusion
UF6 is passed through a fine porous filter and U235 being slightly lighter than U238 moves faster which lead to a slightly higher concentration of U235 on the other side of the filter. The process must be repeated 1,200 times to yield the a concentration of 3% U235 and is very energyware intensive.
- gas centrifugation
The isotope U238 is heavier than U235 and the centrifugal forces will tend to separate the two by pressing U238 to the outer wall of the centrifuge while U235 stays closer to the axis. The process must be repeated many times, but the energyware consumption is still about ten times lower than for the diffusion process.

Electricity consumed during enrichment using gaseous diffusion is generated with a nuclear power plant and a hard coal power plant for the French and the US-American enrichment plant, respectively. Consumption of chemicals and materials, other energyware and water as well as radionuclide emissions are other factors considered in the operation phase of the enrichment plants.

The different nuclear power nations purchase of nuclear fuel enriched with either method has been taken into account. 77% of nuclear fuel used in the UCPTE* countries is assumed to have been enriched with the diffusion process (83% in France and 17% in USA) and 23% with the centrifugal process (74% in UK and 6% in Russia). Data concerning this distribution has been calculated based on figures from literature and on the main suppliers' market share.

Construction phase of enrichment plants is included as well as energyware consumption and solid wastes during the demolition phase.

Fuel fabrication
Fuel fabrication of virgin uranium is included: solid UF6 is heated into gaseous state, conversion into uranium dioxide powder, compression into cylindrical pellets, sintering and grinding, pellets are placed in zircaloy (zirconium alloy) tubes, tubes are pressurized with helium and sealed to form fuel rods, rods are bundled into fuel assemblies. Literature data mainly from two plants - one in Germany and one in USA - have been used. Construction of plant is included as well as demolition.

Nuclear power plant
Two Swiss light water nuclear power plants have been inventoried with respect to construction, operation and demolition - one BWR (Boiling Water Reactor) and one PWR (Pressurized Water Reactor), both about 1000 MW e and 25500 TJ net electricity production per year. Data about construction and demolition has been adapted to UCPTE conditions (90% PWR and 10 % BWR). Country specific radionuclide emissions are applied for French, German and Swiss nuclear power plants. Test operation of diesel-fuelled reserve power is included.

Reprocessing
Though severel of the UCPTE* nuclear power nations do not use reprocessed fuel, all spent fuel is supposed to be reprocessed in ETH's study. UO2 pellets are dissolved in nitric acid and uranium and plutonium is regained. Construction, operation and demolition has been included.

Interim storage
Before and after reprocessing interim storages are needed for spent uranium fuel and radioactive wastes from the reprocessing plant respectively. The studied interim storage will store high, medium and low level radioactive products. The plant also includes a treatment plant for low level radioactive wastes (incineration and conditioning). Construction, operation and demolition of the plant are included.

Final storage
Two types of final storages have been included in the study, one for low and medium level radioactive wastes in horizontal caverns and one storage for high radioactive waste in vertical shafts deep in the mountain. Studied concepts are not built yet. Encapsulation is included. Construction, operation and sealing of the storages are included. Radionuclide emissions to groundwater are not included.

Transports
Transports of the interim products in the nuclear fuel chain between all plants have been included as well as transports of materials, chemicals and wastes.

* Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.

System Boundaries

Nature Boundary	Used materials and energyware have been followed from extraction and processing of natural resources. Maufacturing processes for the use of recycled material are accounted for. Emissions from energyware use in manufacturing processes and transports (infrastructure and vehicle construction included) are considered as well as emissions from

	landfills (infrastructure included) where waste material is disposed of. Waste material supposed to be recycled are outputs of the system (i.e. those recycling processes are not included). Land is divided into two main groups - land and sea - which are subdivided into 4 categories each. Land Criterion Category Natural human impact not larger than other species' since the industrial revolution I Modified human impact larger than other species', low degree of cultivation II Cultivated human impact larger than other species', large degree of cultivation III Built upon dominated by buildings, roads, dams, mines etc. IV Category I is not used in the study. State of land before, during and after exploitation is of interest. If a piece of land is used again after some kind of exploitation it will either end up in the same category or in a higher one. ETH takes into account not only the land used during the technical lifetime of the studied system but also during the construction phase and during the time it takes to restore the land. They express use of land in the unit m2year which is different from comparable Swedish studies (m2). See times for restoration of land below: From category IV to category III 5 years From category III to category II 50 years From category II to category I 100 000 years (For uranium mines the restoration time to category II is 80'000 years due to elevated radiation caused by long-living radioactive compounds.) ETH's LCI-results comprise all parameters received during inventory and calculation, i.e. no selection has been made by ETH.
Time Boundary	The figures describe the average operation of studied plants in 1994. But for radioactive emissions figures mirrors the period from 1992-1994. Different technical lifetimes/reference times for different parts and materials of the studied systems have been used as follows: Conversion plant 40 years Enrichment plants 30 years Fuel fabriction 30 years Nuclear power plants 40 years Reprocessing plant 30-40 years * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Geographical Boundary	Only the following countries in the UCPTE* do have nuclear power: Germany, Belgium, France, The Netherlands, Switzerland, Slowenia and Spain. Data from one open-pit mine in Canada and two underground mines in the USA have been used as well as general literature data. Data for the uranium ore processing phase come from literature, one plant in Canada and two plants in the USA. Literature data describing American conversion plants have been used. Examined enrichment plants (literature data) are: EURODIF in France and USEC in the USA (gaseous diffusion); URENCO in Germany, UK and the Netherlands, and TENEX in Russia (gas centrifugation). Two Swiss nuclear power plants have been studied in detail concerning their actual fuel chain and their operation. Data received from the Swiss plants has been adapted to the average situation in the UCPTE* region in 1994 with the help of certain specific data from France and Germany. Data about radioactive emissions of nuclear power plants have been received from statistics in Switzerland, France and Germany. Figures from the most modern reprocessing plant in Sellafield, UK (THORP) and a prospected plant in Germany for spent uranium fuel have been used in the study together with other literature data. Studied storage concepts (interim and final) are Swiss. Data concerning the use of resources, emissions and waste in connection with manufacturing processes mainly originate from sources in Switzerland, Germany and other western European countries. * Union pour la coordination de la production et du transport de l'életricité, following

	countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Other Boundaries	The restoration of uranium mines is not included in ETH's study except for land use. Demolition phase of uranium ore processing plant is excluded as well as environmental load on ground and ground water. Material need and energyware consumption in the demolition phase of conversion plant is not included, nor is treatment of operational solid waste. Regaining of hydrofluoric acid in the enrichment phase and the use of depleted UF6 for further extraction of UO2 has not been considered. Depleted UF6 is neither considered as waste. Material need in the operation phase of diffusion plants and in the demolition phase of both kind of enrichment plants has been excluded. Diffusion process in France is supplied by nuclear power, and in USA by coal power. British and Russian centrifugal plants are supplied with UCPTE* electricity (mix of several power systems representativ for the actual situation in the UCPTE region). For the fuel fabrication plants data about some chemical use is missing and emissions during the demolition phase are not complete. Emissions to air and water in the demolition phase of nuclear power plant is not included. The reuse of extracted uranium and plutonium from spent fuel in nuclear power plant operation has not been taken into account. Manufacturing processes of components and machines have been approximated with 50% of the energyware used to produce contained materials. Energyware figures concerning material production come from literature and have assumed to be a mix of 10% UCPTE electricity, 45% oil and 45% natural gas. This approximation has been confirmed in more thorough calculations in ETH:s LCA for coal power. Big accidents occuring seldomly are not included.The threshold is fixed at 10 accidents per year if one energy carrier/system (e.g. oil) would cover the entire primary energy demand of the world.
Allocations	Inventoried data from different literature references has been put together to form indata to the calculated modules within the nuclear fuel cycle: uranium mine, uranium ore processing, conversion, enrichment, fuel fabrication, nuclear power plant, reprocessing, interim storage and final storages for conditioned low, medium and high level radioactive waste. Criterias for chosing certain data is described in the original report from ETH. Criterias are different for different parameters. Allocation in the enrichment phase between different suppliers (diffusion and cetrifugation plants) has been done according to the assumed UCPTE purchase in 1994, i.e. 77% diffusion plants and 23% centrifugal plants. Generally the allocation between different ''stakeholders'' in all steps has been conducted according to the need of uranium and according to the need of uranium disposal. The cutoff-method has been used for material use, i.e. 100% of the environmental load for virgin and recycled material used in the lifecycle is included whereas no environmental load has been considered for materials leaving the system to be recycled. Landfill processes and waste incineration, however, are included for waste arising during the lifecycle.
Systems Expansions	

Flow Data	
General Activity QMetaData	
Date Conceived	1985 to 1995
Data Type	Derived, unspecified
Represents	Average nuclear power in the UCPTE countries.
Method	The figures have been copied from the module '''Electricity from nuclear power, UCPTE'' (Strom ab KKW, UCPTE) (KKW=Kernkraftwerk) in the Ökoinventare von Energiesystemen, ETH Zürich 1996.
Literature Reference	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz, Environmental Life-Cycle Inventories of Energy Systems An Environmental Database for the Accounting of Energy Consumption in Product Life-Cycle Assessment and the Comparative Assessment of Energy systems Prof. Dr. P. Suter, R. Frischknecht, et al Swiss Federal Institute of Technology, Zürich R. Dones, U. Gantner Paul Scherrer Institute, Villigen/Würenlingen
Notes	Multiple flows are reported for several emissions to air. This is because that in the original study emissions to air have been reported in three categories, indicated by one of the letters below following the substance name. - m = mobile (emissions from vehicles) - p = process (process specific emissions as for instance methane emissions during coal mining) - s = stationary (emissions from stationary combustion plants) This categorisation has however not been documented in this specification in the SPINE format.

About Inventory

Publication	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz. ETH, Eidgenössische Technische Hochschule, Zürich, Gruppe Energie - Stoffe - Umwelt (ESU), Paul Scherrer Institut, Villigen/Würenlingen, Sektion Ganzheitliche Systemanalysen Available on CD-ROM with full documentation (in German) at http://www.energieforschung.ch. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by (see also Notes): Rolf Frischknecht, ESU-services, Switzerland Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	Original study of ETH: LCA pra
General Purpose	The purpose of the ETH study was to examine a number of energy systems quantitatively and to the same extent with respect to environmental issues during their lifecycles. The results can be used in lifecycle assessments, as basis information in decisionmaking regarding environmental optimisation or in working with municipal energy plans.
Detailed Purpose	ETH:s aim of this LCI was to describe the averag situation in UCPTE concerning electricity generation with nuclear power. Material and energyware needs, emissions and solid waste have been inventoried in all steps of the nuclear fuel cycle regarding construction, operation and demolition phases all through the lifecycle.
Commissioner	BEW, PSEL - Bundesamt für Energiewirtschaft, Projekt- und Studienfonds der Elektrizitätswirtschaft .
Practitioner	Rolf Frischknecht et al - ETH, Eidgenössische Technische Hochschule, Institut für Energietechnik, Zürich and Paul Scherrer Institut, Sektion Ganzheitliche Systemanalyse, Villingen/Würenlingen .
Reviewer	None, see further under notes -
Applicability	Data reported here is supposed to be representative for nuclear power in the UCPTE countries in 1994.

About Data	The exactitude concerning radioactive emissions to air and water is ±50%. Data concerning construction of UCPTE nuclear power is probably slightly overestimated since a major part of French and German nuclear power plants have a capacity of about 1300 MWe. Material manufacturing processes have been inventoried with a low degree of exactitude (except for steel, cement, aluminium, copper, bitumen, and platinum group metals for which rather detailed LCI data are provided). Results are reported with three figures, but it is stated in the original source that this does not mean that accuracy is that high (Part III, p.16). For references and sources of reported figures see further under Function, Nature boundary, Geographical boundaries, Publication, Notes and General metadata.
Notes	Reviewer of this specification of metadata describing the ETH study has been: Dr. Rolf Frischknecht, ESU-services (earlier at ETH) - approval of Vattenfall's interpretation ot the documentation Ann-Christin Pålsson, CPM - review of documentation quality according to the CPM data documentation requirements. Project Management of the ETH study, 3rd edition: Professor, Dr. P. Suter and R. Frischknecht, ETH Editorial staff of the 1st edition: R. Frischknecht, P. Hofstetter, I. Knoepfel, M. Ménard, ETH R. Dones, E. Zollinger, Paul Scherrer Institut Authors of the 1st edition: N. Attinger, T. Baumann, G. Doka, R. Dones, R. Frischknecht, H.-P. Gränicher, C. Grasser, P. Hofstetter, I. Knoepfel, M. Technical System	
Name	Nuclear power plant with support systems
Functional Unit	Net production of 1 kWh electricity
Functional Unit Explanation	The emissions and use of resources and raw materials are associated with the production of 1 kWh electricity.
Process Type	Cradle to gate
Site	Forsmark nuclear power plant
Sector	Grid electricity and district heat
Owner	Forsmark nuclear power plant
Technical system description	The studied system include the *nuclear fuel chain and the operation and maintenance of the nuclear power plant*. The fuel chain include: extraction in mine, conversion, enrichment, fuel production, handling of used nuclear fuel and waste and final storage. Production of materials, chemicals and electricity and transports, used in association with the fuel chain and the operation and maintenance of the plant are included.

	To represent the nuclear power plants of Vattenfall, Forsmark has been studied. Forsmark has 3 boiling-water reactors (BWR). Forsmark 3 has been chosen for detailed study. *Technical data* for the reactors at Forsmark: Forsmark 1: Effect, net: 970 MW; Average annual production: 6600 GWh; operation time: 6800 hours/year. Forsmark 2: Effect, net: 970 MW; Average annual production: 6600 GWh; operation time: 6800 hours/year. Forsmark 3: Effect, net: 1158 MW; Average annual production: 7600 GWh; operation time: 6565 hours/year. ***Uranium extraction and uranium plant*** The uranium ore is extracted in an open cast mine in Key Lake, Canada, with a content of U3O8 of 2,22%. After the mining, the ore is transported to a uranium plant where uranium concentrate is produced from the uranium ore. The plant is located 1,5 km from the mine. Large amounts of chemicals e.g. sulphuric acid and ammonia are used in the process. The sulphuric acid is produced in connection with the plant. The uranium concentrate is transported in barrels on trucks to the conversion plant, located 4000 km away. ***Conversion*** At conversion the uranium concentrate is converted to uraniumhexaflouride (HF6) through a reaction with flouride hydrogen and flouride. The conversion takes place in two steps and the uranium is transported 600 km by truck between the two steps. After the conversion, the uraniumhexaflouride is transported to France and Holland via truck and boat and railway for enrichment. ***Enrichment*** At enrichment, the share of the fissionable isotope uranium-235 are increased from 0,7% to 3% (the rest of the uranium is uranium-238). Two different processes can be used; the centrifugal method and the gaseous diffusion method. The studied system concern uranium where 60 % is assumed to be produced with the centrifugal method and 40 % with the gaseous diffusion method. Enrichment according to the gaseous diffusion process takes place in France. The process is very energy demanding; 3-4% of the energy produced, are used in the process. French average electricity mix have been used in the calculations. 100% nuclear power could be used in the calculations, since four 900 MW nuclear power reactors have been built in connection with the enrichment plant. Enrichment according to the centrifugal method are assumed to take place in Holland. The process is not as energy demanding as the gaseous diffusion process; 0,1 % of the energy produced, is used in the process. Vattenfall also buys enrichment services according to this process from England, Germany and Russia. ***Fuel production*** In the fuel plant uraniumhexaflouride is converted to uranium dioxide in powder form. The powder is pressed to 1 cm long pellets, that are inserted into rods manufactured of zirconium alloy. The rods are mounted together in a sheet-metal box. Control rods are also manufactured in the fuel plant. These mainly consist of stainless steel. The fuel is transported to the nuclear power plant. ***Operation and maintenance*** Medium active waste and some low active waste from the operation and maintenance of the plant are transported to SFR (Final storage for low and medium active radioactive waste), situated in a mountain room below sea level at Forsmark. The transport to SFR takes place with special vehicles from Forsmark. ***Handling of used nuclear fuel and waste and final storage*** Every year, 20 % of the fuel is replaced. The used nuclear fuel are taken to CLAB (Central storage for used fuel) where it is stored (mellanlagras). The used fuel is handled in special transport containers. The weight of these have been accounted for as a standard addition of 10% to the transport. After 40 years of storage, the used fuel are encapsulated in CLAB2 and final stored. The encapsulation are planned to take place in connection to CLAB. The capsules are assumed to have double walls of steel and copper. The inner part has a 5 cm thick wall of steel with a 5 cm thick copper coating. The capsule will possibly also contain some sort of filling material. Crushed glass are assumed. The final storage will be closed about 40 years after the last nuclear reactor have been taken out of use.

System Boundaries

Nature Boundary	All emissions are considered equivalent, independent of where they take place (locally, regionally, globally; in densely populated areas or rural areas).

Time Boundary	The nuclear power plant are assumed to have an operation time of 40 years. Sensitivity analysis is performed after 25 years, since this life-time often are mentioned in the political debate. The final storage for used nuclear fuel is in this study considered to be closed after 40 years after the nuclear power plant have been taken out of use. Any emissions from the closed final storage are not included.
Geographical Boundary	The nuclear power plant is located in Forsmark. The mining of uranium ore takes place in Key Lake, Canada. The enrichment is located in Holland and France and the fuel production in Sweden.

Other Boundaries	The studied system include the *nuclear fuel chain and the operation and maintenance of the nuclear power plant*. Calculations of building and demolition of the plant has been performed but are not included in this system. ***Sub-systems included in the system:*** • Use of resources and emissions associated with reinvestments and reconstruction. Concrete constructions and buildings are however not considered to need renewal during the lifetime of the power station. • The entire fuel chain have been studied, from fuel production to waste handling. • The building and demolition of the Swedish plants for storage of operation waste, and used fuel are included e.g. SFR(Final storage for low and medium active radioactive waste), CLAB(Central storage for used fuel), encapsulation station and deep storage. • Energy and raw material use for the production of the materials in the capsules are included. • Electricity used in the nuclear power plant, to run supply water and cooling water pumps is included. Diesel oil used as reserve- and backup power for the plant are included. • Known use of chemicals are accounted for. In the cases where it was possible to obtain data, resource use and emissions for the production are included. • Use of resources and emissions to air, from production of the electricity that is used in the life cycles. • Energy use and emissions for the production of oil for the studied manufacturing processes and transports. ***Sub-systems excluded from the system:*** • The building of plants for extraction, conversion and enrichment of uranium and manufacture of fuel are not included since the serve several users. • Emissions and energy use in the encapsulation plant. • Environmental influence from major accidents is not included, a number of risk studies have already been performed. • Equipment after the power station transformer. • Waste and rest products are transported to final waste. Operation and chemical and biological decomposing processes (nedbrytningsprocesser) in the final waste have not been considered. • The risk of major accidents and rare breakdowns and environmental consequences from these. • Work environment. • Environmental loads caused by the operation personnel.
Allocations	The *50/50 method* has been applied throughout the calculations. The method is described in ´Nordic Guidelines on Life-Cycle Assessment´, Nord 1995:20, The Nordic Council, Stockholm. Copper used for encapsulation of used nuclear fuel are assumed to be 100% virgin source.
Systems Expansions	

Flow Data

General Activity QMetaData	
Date Conceived	
Data Type	Derived, unspecified
Represents	Average nuclear power in the UCPTE countries.
Method	An LCA calculation of fuel production, operation and maintenance and handling of rest products for a nuclear power plant.
Literature Reference	Brännström-Norberg B-M., Dethlefsen U., Johansson R., Setterwall C., Tunbrant S.,''Livscykelanalys för Vattenfalls elproduktion - Sammanfattande rapport'', Vattenfall AB
Notes	The parameters that are presented are chosen because they have a general interest and because the basis for these parameters are relatively good. All values are reported with 3 figures. The data are however seldom that accurate.

About Inventory

Publication	Brännström-Norberg B-M., Dethlefsen U., Johansson R., Setterwall C., Tunbrant S.,''Livscykelanalys för Vattenfalls elproduktion - Sammanfattande rapport'', Vattenfall AB Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology
Intended User	The data can be used as a basi
General Purpose	• The work with life-cycle analysis are expected to *contribute to a reinforcement and structuring* of the environmental work within Vattenfall, and a deeper knowledge on the use of resources and emissions to the environment. • An LCA can *facilitate a need for reliable data for electricity production.* Electricity is used in the manufacture of almost every product, and data from an LCA can be used when conducting an LCA on products. • An LCA can *facilitate a choice between different techniques* for future electricity production. • An LCA can also help to *choose the most effective alternatives* to reduce the consumption of resources and environmental influence of the current electricity production system. • It is also possible to *compare* the environmental load for different alternatives of electricity production.
Detailed Purpose	To obtain a *reliable basis* to be able to perform life-cycle analyses of different types of electricity use, and to identify opportunities for improvements in the existing system. To identify data gaps and areas where the knowledge are poor.
Commissioner	- Vattenfall Elproduktion .
Practitioner	- Vattenfall Energisystem AB: Britt-Marie Brännström-Norberg Ulrika Dethlefsen Roland Johansson Caroline Setterwall Sofie Tunbrant .
Reviewer	- Thomas Ekvall, Chalmers Industriteknik (CIT) Gunnar Lindfors, Institutet för Vatten- och Luftvårdsforskning (IVL) Göran Finnveden, Institutet för Vatten- och Luftvårdsforskning (IVL)
Applicability	The analysis are based on data from plants that are chosen to make the analysis representative for the fuel production, operation and maintenance and handling of rest products of Vattenfall:s nuclear power plants. The data are reliable since specific plants have been studied. The consequence is however that the result is primarily valid for the studied plant. Thoroughly reliable data for every power source, requires life cycle analyses for a large number of power plants for every power source. Nuclear and water power are the base for Vattenfall:s electricity production system. The studied nuclear power plant, Forsmark, has 3 *boiling-water reactors (BWR).* Other reactors in Sweden are mainly of BWR-type, while most light-water reactors in the rest of the world are pressurised-water reactors (PWR). Transmission and distribution losses are not included. When the result is used to study different types of electricity use, these losses should be included. A rough estimate are that the distribution losses for a large industry customer are approximately 5% of the bought electricity, i.e. to obtain data for the use of electricity the data should be multiplied with 1,05. For an average household customer the transmission losses are approximately 10% of the bought electricity, i.e. the data should be multiplied with 1,10. The study concern *uranium extracted* from an open-cast mine in Canada. The influence of choosing another mine is not clear. A rough estimate are that the chosen mine represents a middle alternative - there are both better and worse mines.

	The study concerns uranium that is to *60 % enriched with the centrifugal method and to 40 % with the gaseous diffusion method*, which was representative for the acquisitions of uranium by Vattenfall in 1993. The choice of distribution between the two methods has a great influence on the energy use and therefore on the results. The study concerns *radioactive waste* that are stored and encapsulated at CLAB, which is characteristic for Vattenfall:s nuclear power and Swedish nuclear power, but not for nuclear power in other countries. The result would be significantly affected if the waste were handled in a different way. The complete study include building, operation and maintenance, and demolition of the power plant and fuel production and handling of rest products from the fuel. When the data is used for energy production in a life cycle analysis of a product or a system, that do not require expansion of the electricity production system, it however reasonable only to include fuel production, operation and maintenance and handling of rest products from the fuel. The other phases of the life cycle are the same independent on the electricity production.
About Data	The data that has been used are primarily from *Forsmark nuclear power plan*t. Forsmark has 3 boiling-water reactors (BWR). Forsmark 3 has been chosen for detailed study, because it is most recent built and it is also built with the strictest requirements. The *fuel production chain include uranium extraction from mine, uranium plant, conversion, enrichment and fuel production.* In the calculations actual values from 1993 have been used, to account for the use of resources and emissions. The choice of plants have been made from the plants type-value ("an average plant") and the possibility to obtain data. The mine, uranium plant and conversion plant are located in Canada. Enrichment takes place in France and Holland and fuel production in Sweden. Relevant data for transports, extraction and production of metals and chemicals, and manufacture and work on important components were hard to obtain. Data from manufacturers and other reports and studies, primarily life cycle analyses have been used. Production of material and transports are considered with current technology. Swedish standard values have been used to calculate fuel use and emissions from transports. Transport distances are specific for the operation of the plant. *The parameters that are presented* are chosen because they have a general interest and because the basis for these parameters are relatively good. All values are reported with 3 figures. The data are however seldom that accurate. The mine chosen as example in the analysis is Key Lake in Canada. The motive is that the deliveries in 1993 were biggest from this mine. In 1993 40 % of the uranium used in VattenfallÆs nuclear power plants came from Key Lake mine in Canada, 24 % from Olympic Dam mine in Australia, and 36 % from Novouralsk in Russia. Key Lake is also probably in a middle position concerning environmental influence of the three suppliers. The uranium from Novoralsk are considered to give the lowest environmental effects. It is not clear, through allocation reasons how Key Lake compares to Olympic Dam. At enrichment, 60 % of the uranium is assumed to be produced with the centrifugal method and 40 % with the gaseous diffusion method. Enrichment according to the *gaseous diffusion process* takes place in France. The process is very energy demanding; 3-4% of the energy produced, are used in the process. French average electricity mix have been used in the calculations. 100% nuclear power could be used in the calculations, since four 900 MW nuclear power reactors have been built in connection with the enrichment plant. The calculations of emissions for electricity production for enrichment in France are therefore very conservative. Enrichment according to the *centrifugal method* are assumed to take place in Holland. The process is not as energy demanding as the gaseous diffusion process; 0,1 % of the energy produced, is used in the process. Vattenfall also buys enrichment services according to this process from England, Germany and Russia. The total volume of *low and medium active radioactive operation waste* from a nuclear power that has operated for 40 years is calculated to be 70000m3. It consists e.g. of

	protective clothing, tools and replaced parts used in the active area of the plant, and equipment to purify the process water. *Medium active waste and some low active waste* are transported to SFR (Final storage for low and medium active radioactive waste), situated in a mountain room below sea level at Forsmark. Actual average values from SFR have been used in the analysis. The transport to SFR takes place with special vehicles from Forsmark. The transports demands energy and causes some emissions from combustion of oil products. Every year, *20 % of the fuel is replaced*. The used nuclear fuel are taken to CLAB (Central storage for used fuel) where it is stored (mellanlagras). Actual average values from CLAB have been used in the analysis. After 40 years of storage, the used fuel are encapsulated in CLAB2 and final stored. The encapsulation are planned to take place in connection to CLAB. The used fuel is handled in special transport containers. The weight of these have been accounted for as a standard addition of 10% to the transport. Data for material and transport needs for *plants for the handling of nuclear waste* are derived from SKB concept for deep storage. These are based on the fact that the Swedish nuclear power program will be ended in 2010, equivalent to 30 years operation with current operation. In this analysis, SKB:s calculations for 25 years operation have been used. The environmental influence of these plants for used nuclear fuel will then be overestimated. Use of resources and emissions associated with *reinvestments and reconstruction* are included. They are generally assumed to give an addition of 1 % per year of the use of resources and emissions at the building phase. Concrete constructions and buildings are however not considered to need renewal during the lifetime of the power station. The following data for Forsmark 3 has been used in the calculations (tonnes per year under 40 years) Steel: 22,80 Copper: 0,75 Lead: 6,23 Aluminium: 1,70 Titanium: 0,05 PVC: 5,82 For electricity used in the manufacture of materials and fuels, *average electricity* for the respective countries, distributed on the different electricity production alternatives have been used. The following *degrees of efficiencies* have been used to calculate the fuel used in the electricity production. The values are standard values for existing power plants. New modern plants often have higher degrees of efficiencies. The values are calculated from the effective heat value in the used fuels and the energy content in the steam produced in a nuclear power plant. • Coal condensing: 40% • Oil condensing: 40% • Natural gas condensing/combination: 40% • Gas turbine: 25% • Combined heat and power plant(irrespective of fuel) 30% (for electricity production) 85% (total for electricity and heat production) • Water power: are not recalculated, are accounted for as kWh electricity • Nuclear power: 33%, are however not recalculated, but accounted for as kWh electricity or gram natural uranium.
Notes	Mining of uranium ore gives a local environmental effect during extraction. The water recipient are influenced through emission of heated cooling water from the power plant.

SPINE LCI dataset: OECD Europe, electricity generation mix 1998

Administrative	
Finished	Y
Date Completed	2001-01-31
Copyright	IEA
Availability	Public

Technical System	
Name	OECD Europe, electricity generation mix 1998
Functional Unit	Total electricity produced during 1998
Functional Unit Explanation	The electricity mix refer to the total amount of electricity generated by different power sources expressed in GWh during the year 1998.
Process Type	Unit operation
Site	OECD Europe
Sector	Energyware
Owner	OECD Europe
Technical system description	The generation of electricity with different power generating systems in the OECD Europe during the year 1998. OECD (Organisation for Economic Co-Operation and Development) Europe includes Austria, Belgium, Czech Republic, Denmark, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Luxembourg, Netherlands, Norway, Poland, Portugal, Spain, Sweden, Switzerland and United Kingdom.

System Boundaries	
Nature Boundary	Not applicable, since the data only refer to the electricity generation mix. The environmental load for generation of electricity is not included.
Time Boundary	The data refer to 1998.
Geographical Boundary	Only electricity produced in Australia is considered. Import or export of electricity is not included.
Other Boundaries	-
Allocations	Not applicable
Systems Expansions	Not applicable

Flow Data	
General Activity QMetaData	
Date Conceived	1998
Data Type	Derived, statistics
Represents	Average nuclear power in the UCPTE countries.
Method	The data are collected from IEA Statistics.
Literature Reference	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8, page II.300.
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

About Inventory

Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998

Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998

	European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998

Technical System	
Name	Oil condensing power plant with support systems
Functional Unit	Net production of 1 kWh electricity
Functional Unit Explanation	The emissions and use of resources and raw materials are associated with the production of 1 kWh electricity.
Process Type	Cradle to gate
Site	Stenungsund oil condensing power plant
Sector	Grid electricity and district heat
Owner	Stenungsund oil condensing power plant
Technical system description	The studied system include *fuel production and operation and maintenance of a oil condensing power plant.* To represent the electricity production of Vattenfall in oil condensing power plants, Stenungsund, is studied. The plant is used for reserve power. The power plant is assumed to operate on fuel oil 1 (Eo1) produced from crude oil from the Norwegian continental-shelf. The fuel has a sulphur content of 0,1 %. The

	plant has a harbour, where oil is landed via pipe-line to an oil storage. Production of materials, chemicals and electricty and transports, used in association with the fuel chain and the operation and maintenance of the plant are included. *The fuel production* include drilling and extraction of crude oil, maintenance and reinvestments of the oil platforms, transport to the refinery in Mongstad, Norway, where the oil is refined to fuel oil 1 and transport from the refinery to the power plant. Coal condensing power plants are generally fired with fuel oil, Eo5, Eo1 or WRD oil (wide range distillate). The sulphur content of the oil is below 0,2% and 0,1% respectively, equivalent to 50 and 25 mg S/MJ. The Eo1 oil is refined from crude oil extracted in the North sea, while the origin of the heavy fuel oil (Eo2 and Eo5) varies. *Technical data* for the studied power plant: Annual time of use (recalculated as operation time at full effect) (hours): 1000 Supplied fuel effect (MW): 2100 Electricity effect, net (MW): 820 Assumed life-time (years): 60 Electricity production (net) during 60 years (TWh): 49,2

System Boundaries

Nature Boundary	The analysis starts with *extraction of crude oil.* All emissions are considered equivalent, independent of where they take place (locally, regionally, globally; in densely populated areas or rural areas).
Time Boundary	The plant is assumed to have an operation time of 60 years.
Geographical Boundary	The plant is located i Stenungsund. The fuel used in the plant, are refined from crude oil from the Norwegian continental-shelf. The oil is transported by tanker to the refinery in Mongstad (Norway), and then as fuel oil 1 with tanker to the power plant.
Other Boundaries	The studied system included *fuel production and operation and maintenance of a oil condensing power plant.* Calculations of building and demolition have been performed but are not included in this system. ***Sub-systems included in the system:*** • The fuel chain include extraction of crude oil in the North sea, transport of crude oil, refining, oil transport to the power plant and combustion. • Transports in association with operation and maintenance of the power plant. • Reinvestments for the plant except buildings, transformers and cables • Known use of chemicals are accounted for. In the cases where it was possible to obtain data, resource use and emissions for the production are included. • Use of resources and emissions to air, from production of the electricity that is used in the life cycles. • Energy use and emissions for the production of oil for the studied manufacturing processes and transports. ***Sub-systems excluded from the system:*** • Reinvestments of buildings, transformers and cables, since the plant is only used for reserve power. • The prospecting for oil, building and demolition of factories, oil platforms, oil tankers and oil refineries. • Equipment after the power station transformer are not included.

	• Waste and rest products are transported to final waste. Operation and chemical and biological decomposing processes (nedbrytningsprocesser) in the final waste have not been considered. • The risk of major accidents and rare breakdowns and environmental consequences from these. • Work environment. • Environmental loads caused by the operation personnel.
Allocations	The *50/50 method* has been applied throughout the calculations. The method is described in ''Nordic Guidelines on Life-Cycle Assessment'', Nord 1995:20, The Nordic Council, Stockholm. Crude oil for production of fuel to the plant are assumed to be extracted together with natural gas. Data were obtained from Kristin Keiserås Bakkane, Novatech a.s. ''Life Cycle Data for Norwegian Oil and Gas'', that were based on the production at Norwegian oil fields in 1991. An average value for the extracted energy oil (78,6%) and gas (21,3%) for the year in question were used. In reality the distribution between extracted energy for oil and gas respectively, varies. Data has been allocated according to the average value, *i.e. 78,6% of emissions and use of resources are allocated to the crude oil production.* Equipment, use of resources and emissions used only in association with the extraction of one energyware are allocated 100% to that. The oil is assumed to be refined in Mongstad, Norway. Data for production of fuel oil 1 have been obtained from Statoil. The allocation between the different products in the refinery are not known.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	
Data Type	Unspecified, expert outspoke
Represents	OECD electricity generation mix
Method	An LCA calculation of fuel production, operation and maintenance of an oil condensing power plant.
Literature Reference	Brännström-Norberg B-M., Dethlefsen U., Johansson R., Setterwall C., Tunbrant S.,''Livscykelanalys för Vattenfalls elproduktion - Sammanfattande rapport'', in Swedish, Vattenfall AB
Notes	The parameters that are presented are chosen because they have a general interest and because the basis for these parameters are relatively good. All values are reported with 3 figures. The data are however seldom that accurate. The extraction of oil, including transport are responsible for a large share of the NOx-emissions. The combustion (after flue gas cleaning) contributes to the largest emissions of SO2 and CO2. The combustion also gives the largest NOx-emissions.

About Inventory

Publication	Brännström-Norberg B-M., Dethlefsen U., Johansson R., Setterwall C., Tunbrant S.,''Livscykelanalys för Vattenfalls elproduktion - Sammanfattande rapport'', Vattenfall AB Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology
Intended User	The data can be used as a basi
General Purpose	• The work with life-cycle analysis are expected to *contribute to a reinforcement and structuring* of the environmental work within Vattenfall, and a deeper knowledge on the use of resources and emissions to the environment. • An LCA can *facilitate a need for reliable data for electricity production.* Electricity is used in the manufacture of almost every product, and data from an LCA can be used when conducting an LCA on products. • An LCA can *facilitate a choice between different techniques* for future electricity production. • An LCA can also help to *choose the most effective alternatives* to reduce the consumption of resources and environmental influence of the current electricity production system. • It is also possible to *compare* the environmental load for different alternatives of electricity production.
Detailed Purpose	To obtain a *reliable basis* to be able to perform life-cycle analyses of different types of electricity use, and to identify opportunities for improvements in the existing system. To identify data gaps and areas where the knowledge are poor.
Commissioner	- Vattenfall Elproduktion .
Practitioner	- Vattenfall Energisystem AB: Britt-Marie Brännström-Norberg Ulrika Dethlefsen Roland Johansson Caroline Setterwall Sofie Tunbrant .
Reviewer	- Thomas Ekvall, Chalmers Industriteknik (CIT) Gunnar Lindfors, Institutet för Vatten- och Luftvårdsforskning (IVL) Göran Finnveden, Institutet för Vatten- och Luftvårdsforskning (IVL)
Applicability	The studied system included fuel production and operation and maintenance of a oil condensing power plant. The analysis are based on data from a plant that are chosen to make the analysis *representative for operation and maintenance of Vattenfall:s oil condensing plants.* The oil condensing plants are used as *reserve power* and

	primarily at transient needs. The data are reliable since a specific plant have been studied. The consequence is however that the result is primarily valid for the studied plant. Thoroughly reliable data for every power source, requires life cycle analyses for a large number of power plants for every power source. The chosen plant, Stenungsund power plant is responsible for the larger share of Vattenfall:s electricity production in oil condensing power plants. The principle for how a condensing power plant works is not different today, compared to when the plant in Stenungsund was built in the late 1950s. The current boilers have however low-NOx combustion, that together with NOx-cleaning brings about lower emissions of NOx than calculated in this study. Transmission and distribution losses are not included. When the result is used to study different types of electricity use, these losses should be included. A rough estimate are that the distribution losses for a large industry customer are approximately 5% of the bought electricity, i.e. to obtain data for the use of electricity the data should be multiplied with 1,05. For an average household customer the transmission losses are approximately 10% of the bought electricity, i.e. the data should be multiplied with 1,10. Coal condensing power plants are *generally fired with fuel oil*, Eo5, Eo1 or WRD oil (wide range distillate). The sulphur content of the oil is below 0,2% and 0,1% respectively, equivalent to 50 and 25 mg S/MJ. The Eo1 oil is refined from crude oil extracted in the North sea, while the origin of the heavy fuel oil (Eo2 and Eo5) varies. The data used for *oil extraction* are representative for the Norwegian oil fields in use at present, but not for the extraction that will take place after the year 2000, when new modern fields are taken in operation. The complete study include building, operation and maintenance, and demolition of the power plant and fuel production. When the data is used for energy production in a life cycle analysis of a product or a system, that do not require expansion of the electricity production system, it however reasonable only to include fuel production and operation and maintenance. The other phases of the life cycle are the same independent on the electricity production.
About Data	The studied plant is an *existing power plant in Stenungsund*, that is used for reserve power. The power plant is assumed to operate on fuel oil 1 (Eo1) produced from crude oil from the Norwegian continental-shelf. The fuel has a sulphur content of 0,1 %. Data for the use of resources and energy for operation of the power stations are specific for the studied plant. Relevant data for transports, extraction and production of metals and chemicals, and manufacture and work on important components were hard to obtain. Data from manufacturers and other reports and studies, primarily life cycle analyses have been used. Production of material and transports are considered with current technology. Swedish standard values have been used to calculate fuel use and emissions from transports. Transport distances are specific for the operation of the plant. *The parameters that are presented* are chosen because they have a general interest and because the basis for these parameters are relatively good. All values are reported with 3 figures. The data are however seldom that accurate. Data for *extraction of crude oil* were obtained from Kristin KeiserÕs Bakkane, Novatech a.s. "Life Cycle Data for Norwegian Oil and Gas", that were based on the production at Norwegian oil fields in 1991. Use of resources and emissions associated with *reinvestments and reconstruction* are generally assumed to give an addition of 0,5% per year of the use of resources and emissions at the building phase. Buildings, transformers and cables are however not considered to need renewal during the lifetime of the power station. The low level on reinvestments is explained by the fact that the plant is only used for reserve power and therefore proportionately little. The following data has been used (tonnes per year during 60 years): Steel: 3,0 Copper: 0,01

	Aluminium phosphate: 65,1 (of which aluminium: 5,95) Ammonia: 0,50 Sodium hydroxide: 27,4 Hydrochloric acid: 2,60 Slaked lime: 57,5 Transformer oil: 4,05 The emissions from operation of the power plant have been calculated with the following *emission factors*: NOx 50mg/MJ fuel, 6,61e-1 g/kWh electricity SO2 50mg/MJ fuel, 6,61e-1 g/kWh electricity CO 15 mg/MJ fuel, 1,38e-1 g/kWh electricity Particles 10 mg/MJ fuel, 9,20e-2 g/kWh electricity HC (from the power plant) 4 mg/MJ fuel, 3,71e-2 g/kWh electricity HC (from the oil storage) --mg/MJ fuel, 3,70e-3 g/kWh electricity CO2 74000 mg/MJ fuel, 682 g/kWh electricity For electricity used in the manufacture of materials and fuels, *average electricity* for the respective countries distributed on the different electricity production alternatives have been used. The following degrees of efficiencies have been used to calculate the fuel used in the electricity production. The values are standard values for existing power plants. New modern plants have often higher degrees of efficiencies. The values are calculated from the effective heat value in the used fuels and the energy content in the steam produced in a nuclear power plant. • Coal condensing: 40% • Oil condensing: 40% • Natural gas condensing/combination: 40% • Gas turbine: 25% • Combined heat and power plant(irrespective of fuel) 30% (for electricity production) 85% (total for electricity and heat production) • Water power: are not recalculated, are accounted for as kWh electricity • Nuclear power: 33%, are however not recalculated, but accounted for as kWh electricity or gram natural uranium.

Availability	Public

Technical System	
Name	Oil electricity energy system, EPD-version
Functional Unit	1 TJ net electricity from power plant
Functional Unit Explanation	The generation of 1 TJ (1 000 000 000 000 J) net electricity (i.e. electricity need in the power plant has been supplied for by the plant itself). Electricity distribution and distribution losses are not accounted for, i.e. not for this particular unit process. Data about distribution and its losses may however be found in the original study.

Process Type	Cradle to grave
Site	UCTPE countries Europe
Sector	Grid electricity and district heat
Owner	UCTPE countries Europe
Technical system description	Reported figures are based on data from a LCI-study performed at ETH, Zürich and Paul Scherrer Institut, Villigen, ''Ökoinventare von Energiesystemen'', 3rd edition 1996 and adapted to the demands of the EPD-guidelines (Environmental Product Declaration guidelines in Sweden). -- Brief description -- The phases inventoried in ETH's life cycle stydy of electricity generation with oil are: exploration, extraction (onshore and offshore), transports, refinery, regional distribution and power plant operation. The average situation in the UCPTE* region in 1994 concerning the origin of the oil, transports of different kinds (Swiss conditions), refinery processes, distribution, power plant operation etc. is described. All subsystems are described on a ''cradle-to-grave'' basis, including the main stages, i.e. data concerning consumption of resources, waste handling and emissions is included for the manufacturing of main materials and energyware used in the lifecycle. -- Detailed description -- Exploration Drilling activities during exploration of crude oil (onshore and offshore) have been inventoried regarding use of energyware, drilling chemicals, water, steel and concrete (coating of drilling holes) and use of land/sea bed (not included in the figures, see other boundaries). Besides emissions arising due to use of energyware also emissions of methane and other volatile organic compounds from the drilling holes are included. Crude oil emanating in drilling test is burnt, emissions are included. Offshore exploration leads to emissions of drilling chemicals and drilling sludge to the sea, though a lot of it is cleaned on the platform before it is emitted. Other emissions to the sea are heavy metals from the drilled sea bed, oil and intraformation water. Some of the drilling chemicals and sludge is brought to the shore as waste. Waste of onshore activities are of the same kind. It is put in landfills, land-farming or casted (emissions from these processes are included). Extraction Average on- and offshore extraction has been inventoried regarding construction and demolition of platforms, towers, pipelines etc., use of energyware, materials (steel and concrete) and land/sea bed. Cleaning of crude oil from water and gas is included as well as flaring of gas, leaks, blow-outs and low pressure venting (emissions of mercury and radioactive radon are accounted for since these elements are found in the gas). Different methods of energyware demanding pumping processes are needed when the pressure in the oil source is too low to allow oil from emanating by itself. Water can be pumped into the oil source or gas recovered from the oil source can be compressed and led back into the oil source, there are also several other methods to enhance the oil gain in the extraction process (all these processes are included). Production chemicals, for ex. anticorrosives, and drilling chemicals as well as emissions of those chemicals are included. Onshore, 90% of the intraformation water is assumed to be pumped into hollows deep in the ground the rest is led into a fresh water recipient. Offshore 100% of the intraformation water is emitted to the sea. Shipping of supplies is included. Production waste consist of scale i.e. mineral deposits in equipment and pipelines. Scale is low level radioactive. Dismantling process of oil platforms is not included and the whole platform including drillhole mantelings and pipelines is assumed to be deposited, i.e. no recycling. Long-distance transports The average transport situation has been scanned. Transports with pipeline (on- and offshore), tanker, train, barge and lorry have been taken into account. Construction, demolition and maintenance of infrastructure (vehicles, pipelines, ships) has been included as well as energyware consumption (extraction included), emissions and waste. Electricity consumption and land use of harbours is included. Losses due to vapourization of oil have been taken into account. Oil emissions due to regularly occurring leaks in pipelines and smaller accidents etc. are included. Refineries The major part of oil products consumed in Europe are refined in Europe. Following processes in refineries have been studied: 1. desalination, 2. distillation, 3. coking (cracking process), 4. visbreaking (lowering of viscosity), 5. hydrotreating (cleaning from e.g. sulphur), 6. catalytic cracking, 7. hydrocracking, 8. catalytic reforming, 9. isomerization, 10. alkylation, 11. steamreforming and 12. steamcracking. Losses due to flaring of refinery gas is included. Following are the products of the studied refineries: refinery gas, propane and butane, petrol (leaded and unleaded) and naphtha, kerosene and diesel, light oil, heavy oil and bitumen. The products interesting for power plants are light and heavy oil, emanating from successive processes 1,2,4,5,6.

	The use of additives in certain oil products have been scanned and included as organic chemicals. Resource consumption, emissions and waste in connection with construction, demolition and use of operation chemicals and catalysts of refineries have mostly been gathered from literature. Operation parameters regularly meassured - water and energyware consumption, emissions of SO2, NOx, HC and oil to water, waste etc. - have been received from European refineries. For other parameters only a few occasional values were available. For refineries in the former Soviet Union only specific data concerning VOC-emissions and use of energyware were available, for the rest European figures have been used. Regional distribution Transport of fuel from refinery to power plant is assumed to be a 100 km train transport. Power plant Only base load plants, > 100 MWe, fired with heavy fuel oil (average lower heating value 40 MJ/kg, density 1 kg/l, sulphur concentration 2,4 % by weight) are inventoried. Only common flue gas cleaning equipment have been regarded, de-NOx equipment (SCR and primary measures), sulphur cleaning equipment (REA) and particle filters (textile). Data concerning operation emissions of SO2, NOx and particles have been received from statistics of the different UCPTE* countries but for other parameters mostly default values from literature have been used. Chemical use for cooling water treatment and emissions to water are included (general data for all kinds of thermal power plants). Operation data from German power plants has been used regarding wastes. Net efficiency of power plants has been calculated on basis of country specific information and the UCPTE* average came to be 38%. Construction and demolition data has been determined based on data for a stone coal power plant and specific data for oil-fuelled power plants. Following assumptions have been made for the construction phase: base load plant, net efficiency 38%, lifetime 30 years, operation time 5700 h/year. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.

System Boundaries

Nature Boundary	Used materials and energyware have been followed from extraction and processing of natural resources. Maufacturing processes for the use of recycled material are accounted for. Emissions from energyware use in manufacturing processes and transports (infrastructure and vehicle construction included) are considered as well as emissions from landfills (infrastructure included) where waste material is disposed of. Waste material supposed to be recycled are outputs of the system (i.e. those recycling processes are not included). ETH's LCI-results comprise all parameters received during inventory and calculation, i.e. no selection has been made by ETH. Vattenfall's criterion in selecting and aggregating ETH's LCI-results for electricity generation in the UCPTE region has been to make the figures usable as general electricity LCI data in EPDs according to Miljöstyrningsrådets guidelines. Especially parameters (emissions) which have established impact indices - accepted by the EPD system - for one or several environmental impact categories, have been picked out and aggregated as far possible. But also metal and energyware resources have been included, as well as waste, in spite of all waste handling processes related to this dataset being included with respect to use of resources and emissions. The latter is an adaption to other LCI data for electricity generation where waste amounts are reported (since those flows have not been followed to the grave). Since ETH claimes that most of the figures regarding metal emissions have an undefined amount of datagaps all metal emissions are aggregated except for a few which are specified separatly since they are reported for most processes in the lifecycle. Metals are reported as elements although they often are part of compounds. Measuring methods often just give the amounts of the different elements found. All hydrocarbons to water are aggregated to one parameter as well as halogenated organics, since no indices exist (that are accepted by the EPD system so far) for characterisation of the individual substances.
Time Boundary	The figures describe the average operation of studied plants in 1994. But for the flue gas cleaning plant data from 1994/95 have been used. Most of the data used to describe exploration and extraction of oil is younger than 1985. Figures concerning other fuel extraction and processing represent an average of the early nineties. Descriptions and figures of different technical processes come from literature, contractors, public and private institutions and describe the situation of the late eighties. Electricity used during the lifecycle has been assumed to be a mix based on the average generation in the UCPTE* countries between 1990-94 (to level off the large variations in hydro power production over the years).

	All processes, also those conducted in the past, have been assumed to use average technology of the early nineties. Different technical lifetimes/reference times for different parts and materials of the studied systems have been used as follows: Pipelines 30 years Tanker 24 years Barge 30 years Power plant 30 years * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Geographical Boundary	The world has been devided into 7 supply regions for oil: The Middle East, Latin America (including Mexico), North and Central Africa, Europe, former Soviet Union and North America. The European harbours have been grouped into two regions: North Sea Region and the Mediterranean Region. Crude oil from the Middle East, discharged in the Mediterranean harbours, is assumed to pass through the Suez Channel while Middle East oil, discharged in the North Sea Region is supposed to pass Cape Hope. Refinery locations have been devided into three categories: Switzerland, Western Europe and former Soviet Union. Refineries in North America and Africa are assumed to keep the same standard as refineries in Europe. Two refineries in western Europe have been inventoried and one refinery on the border between Poland and German has been studied, the latter based on literature information. Processes conducted outside the UCPTE* region are supposed to be supplied with UCPTE* electricity. Data concerning the use of resources, emissions and waste in connection with manufacturing processes mainly originate from sources in Switzerland, Germany and other western European countries. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Other Boundaries	Manufacturing processes of components and machines have been approximated with 50% of the energyware used to produce contained materials. Energyware figures concerning material production come from literature and have assumed to be a mix of 10% UCPTE electricity, 45% oil and 45% natural gas. This approximation has been confirmed in more thorough calculations in ETH's LCA for coal power. The ETH study comprises figures concerning use of land, usable content in water storages and amount of turbine water which have not been reported here. The two latter have been excluded due to lack of corresponding data in comparable studies. Use of land has been excluded here because of ETH's advanced approach. Land is divided into two main groups - land and sea - which are subdivided into 4 categories each. Land Criterion Category Natural human impact not larger than other species' since the indutrial revolution I Modified human impact larger than other species', low degree of culivation II Cultivated human impact larger than other species', large degree of cultivation III Built upon dominated by buildings, roads, dams, mines etc. IV Category I is not used in the study. State of land before, during and after exploitation is of intererst. If a piece of land is used again after some kind of exploitation it will either end up in the same category or in a higher one. ETH takes into account not only the land used during the technical lifetime of the studied system but also during the construction phase and during the time it takes to restore the land. They express use of land in the unit m2year which is diffrent from comparable Swedish studies (m2). See times for restoration of land below: From category IV to category III 5 years From category III to category II 50 years From category II to category I 100 000 years (For uranium mines the restoration time to category II is 80'000 years due to elevated radiation caused by long-living radioactive compounds.) ETH specifies about 160 radioactive isotopes emitted to air and water. Radioactive emissions reported here are picked out in accordance with SETAC working group report on data

	quality and data availability (to be published in 2001). Big accidents occuring seldomly are not included.The threshold is fixed at 10 accidents per year if one energy carrier/system (e.g. oil) would cover the entire primary energy demand of the world.
Allocations	Allocations have been made with respect to lower heating value or weight. Allocation of flaring and blow-out losses as well as other losses was done with respect to the lower heating value of the two commercialized products: crude oil and natural gas. Other environmental impact in the exploration and extraction phase were allocated to crude oil since only a small part of the natural gas extracted together with crude oil is commercialized. In the refinery, allocation was done in accordance with weight of the oil products in the different subprocesses. The cutoff-method has been used for material use, i.e. 100% of the environmental load for virgin and recycled material used in the lifecycle is included whereas no environmental load has been considered for materials leaving the system to be recycled. Landfill processes and waste incineration, however, are included for waste arising during the lifecycle.

Date Conceived	1985 to 1995
Data Type	Derived, unspecified
Represents	Average electricity generation with oil (larger plants) in the UCTPE countries.
Method	The data has been adapted from the Ökoinventare von Energiesystemen, ETH Zürich 1996 and is an aggregation of the LCI results for the module ''Electricity oil thermal UCPTE'' (Strom oelthermisch, UCPTE).
Literature Reference	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz, Environmental Life-Cycle Inventories of Energy Systems An Environmental Database for the Accounting of Energy Consumption in Product Life-Cycle Assessment and the Comparative Assessment of Energy systems Prof. Dr. P. Suter, R. Frischknecht, et al Swiss Federal Institute of Technology, Zürich R. Dones, U. Gantner Paul Scherrer Institute, Villigen/Würenlingen
Notes	The parameters that are presented are chosen because they have a general interest and because the basis for these parameters are relatively good. All values are reported with 3 figures. The data are however seldom that accurate. The extraction of oil, including transport are responsible for a large share of the NOx-emissions. The combustion (after flue gas cleaning) contributes to the largest emissions of SO2 and CO2. The combustion also gives the largest NOx-emissions.

Flow Table and Specific Meta Data

QMetaData	*Direction*	*FlowType*	*Substance*	*Quantity*	*Min*	*Max*	*Unit*	*Environment*	*Geography*
	Input	Natural resource	Bauxite	10.7			kg	Ground

	Output	Product	Electricity	1			TJ	Technosphere	
Notes: Internal flow! Infrastructure (resources and emissions) and processing of hazardous waste is included.	Output	Residue	Hazardous waste	6.62E+01			kg	Technosphere	
Notes: Internal flow! Infrastructure (resources and emissions) included.	Output	Residue	Highly radioactive waste	1.44E-05			m3	Technosphere	
Notes: Internal flow! Infrastructure (resources and emissions) included, no emissions from landfill assumed. Inert waste deposit is waste at landfill that are inert.	Output	Residue	Inert waste deposit	1.00E+03			kg	Technosphere	
Notes: Internal flow! Infrastructure (resources and emissions) included.	Output	Residue	Low radioactive waste	1.47E-02			m3	Technosphere	
Notes: Internal flow! Infrastructure (resources and emissions) included.	Output	Residue	Medium and low radioactive waste	1.76E-04			m3	Technosphere	
Notes: Internal flow! Infrastructure (resources and emissions) included, as well as emissions from landfill. Reactive waste deposit is waste at landfill that is still reactive.	Output	Residue	Reactive waste deposit	1.00E+03			kg	Technosphere	
Notes: Internal flow! Infrastructure of spreading vehicles and emissions are included. Land farming is a treatment of organic sludge, the sludge is spread on a piece of land and left to degrade. Sometimes plants are grown on the land, but those plants are destroyed.	Output	Residue	Waste in land farming	4.43E+02			kg	Technosphere	
Notes: Internal flow! Infrastructure (resources and emissions) included, as well as emissions from incineration plant.	Output	Residue	Waste to incineration	4.64E+00			kg	Technosphere	

About Inventory

Publication	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz. ETH, Eidgenössische Technische Hochschule, Zürich, Gruppe Energie - Stoffe - Umwelt (ESU), Paul Scherrer Institut, Villigen/Würenlingen, Sektion Ganzheitliche Systemanalysen Available on CD-ROM with full documentation (in German) at http://www.energieforschung.ch. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by (see also Notes): Rolf Frischknecht, ESU-services, Switzerland Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	Original study of ETH: LCA pra
General Purpose	The purpose of the ETH study was to examine a number of energy systems quantitatively and to the same extent with respect to environmental issues during their lifecycles. The results can be used in lifecycle assessments, as basis information in decisionmaking regarding environmental optimisation or in working with municipal energy plans. Vattenfalls purpose - as a commissioner of putting ETH:s data into Spine format with metadata - is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines. Data is supposed to be used together with IEA statistics about electricity generation mixes in the OECD countries/regions.
Detailed Purpose	ETH:s aim was to describe the average situation in UCPTE concerning electricity generation with oil. With the help of assumptions and simplifications following phases of the life cycle are described: exploration (on- and offshore) extraction (on- and offshore), long-distance transports, refinery, distribution and power plant.
Commissioner	BEW, PSEL - Bundesamt für Energiewirtschaft, Projekt- und Studienfonds der Elektrizitätswirtschaft .

Practitioner	Rolf Frischknecht et al - ETH, Eidgenössische Technische Hochschule, Institut für Energietechnik, Zürich and Paul Scherrer Institut, Sektion Ganzheitliche Systemanalyse, Villingen/Würenlingen .
Reviewer	None, see further under notes -
Applicability	Data reported here is supposed to be representative for oil electricity generation in the UCPTE countries in 1994. This set of data is aggregated and documented in accordance with the Swedish EPD-guidelines to be used in combination with IEA statistics concerning electricity generation mixes in OECD countries and regions together with other datasets - based on the ETH study - describing other power generation systems. The EPD-adapted power generation systems in Spine format are named as follows: Fuel gas electricity energy system, EPD-version Biofuel electricity energy system, EPD-version Hydro electricity energy system, EPD-version Lignite electricity energy system, EPD-version Nuclear electricity energy system, EPD-version Stone coal electricity energy system, EPD-version Wind electricity energy system, EPD-version IEA statistics for generation mixes 1998 exist in Spine format for the following 30 countries/regions: OECD total OECD North America OECD Pacific OECD Europe European Union Australia Austria Belgium Canada Czech Rpublic Denmark Finland France Germany Greece Hungary Iceland Ireland Italy Japan Korea Luxembourg Mexico Netherlands New Zealand Norway Poland Portugal Spain Sweden Switzerland Turkey United Kingdom United States
About Data	Material manufacturing processes have been inventoried with a low degree of exactitude (except for steel, cement, aluminium, copper, bitumen, and platinum group metals for which rather detailed LCI data are provided). Results are reported with three figures, but it is stated in the original source that this does not mean that accuracy is that high (Part III, p.16). For references and sources of reported figures see further under Function, Nature boundary, Geographical boundaries, Publication, Notes and General metadata.
Notes	Reviewer of this specification of ETH:s data and metadata has been: Dr. Rolf Frischknecht, ESU-services (earlier at ETH) - approval of aggregation of figures and of Vattenfall's interpretation ot the documentation Ann-Christin Pålsson, CPM - review of documentation quality according to the CPM data documentation requirements. The technical committee of the Swedish Environmental Management Council - approval of method and aggregation of parameters Project Management of the ETH study, 3rd edition: Professor, Dr. P. Suter and R. Frischknecht, ETH Editorial staff of the 1st edition: R. Frischknecht, P. Hofstetter, I. Knoepfel, M. Ménard, ETH R. Dones, E. Zollinger, Paul Scherrer Institut Authors of the 1st edition: N. Attinger, T. Baumann, G. Doka, R. Dones, R. Frischknecht, H.-P. Gränicher, C. Grasser, P. Hofstetter, I. Knoepfel, M. Ménard, H. Müller, M. Vollmer, E. Walder, E. Zollinger

	Authors of the revision, 3rd edition: U. Bollens, S, Bosshart, M. Ciot, L. Ciseri, G. Doka, R. Frischknecht, R Hischier, A. Martin, ETH R. Dones, U. Gantner, Paul Scherrer Institut -- --- Changes made to the data set after publishing in SPINE@CPM--- >>> 6 June 2001: <<< Changes made by Ann-Christin Pålsson, CPM based on discussions with Caroline Setterwall, Vattenfall AB. Comments: The following changes has been made in the nomenclature for in- and outflows: Mangane in ore -> changed to: Manganese in ore CH4 -> changed to: Methane (to be in accordance with the nomenclature specified in CPM report 2000:2) CN -> changed to: CN- Stone coal -> changed to: Hard coal (to be in accordance with the nomenclature specified in CPM report 2000:2) Other metals -> changed to: Metals Explanations of nomenclature (inserted in Notes for the specific flows): - CN- is Cyanide ion - Reactive waste deposit is waste at landfill that is still reactive. - Inert waste deposit is waste at landfill that are inert. Additional clarifications: - Note that the flows of waste in the table of in- and outflows are internal flows, i.e. they do NOT cross the system boundaries. All waste handling processes is included in the study with respect to use of resources and emissions. - Radioactive waste is accounted for in cubic metres. The product specific requirements for electricity and district heating generation (PSR 1998:1) in the Swedish EPD system states that waste shall be accounted for in gram. However, no conversion factors were given in the study. There are also no general conversion factors that are commonly used.

SPINE LCI dataset: Oil electricity energy system, ETH - full version

Administrative

Technical System	
Name	Oil electricity energy system, ETH - full version
Functional Unit	1 TJ net electricity from power plant
Functional Unit Explanation	The generation of 1 TJ (1 000 000 000 000 J) net electricity (i.e. electricity need in the power plant has been supplied for by the plant itself). Electricity distribution and distribution losses are not accounted for, i.e. not for this particular unit process. Data about distribution and its losses may however be found in the original study.
Process Type	Cradle to grave
Site	UCTPE countries Europe
Sector	Grid electricity and district heat
Owner	UCTPE countries Europe
Technical system description	Reported figures come from a LCI-study performed at ETH, Zürich and Paul Scherrer Institut, Villigen, ''Ökoinventare von Energiesystemen'', 3rd edition 1996. Brief description The phases inventoried in ETH's life cycle stydy of electricity generation with oil are: exploration, extraction (onshore and offshore), transports, refinery, regional distribution and power plant operation. The average situation in the UCPTE* region in 1994 concerning the

origin of the oil, transports of different kinds (Swiss conditions), refinery processes, distribution, power plant operation etc. is described.

All subsystems are described on a ''cradle-to-grave'' basis, including the main stages, i.e. data concerning consumption of resources, waste handling and emissions is included for the manufacturing of main materials and energyware used in the lifecycle.

Detailed description

Exploration
Drilling activities during exploration of crude oil (onshore and offshore) have been inventoried regarding use of energyware, drilling chemicals, water, steel and concrete (coating of drilling holes) and use of land/sea bed (not included in the figures, see other boundaries). Besides emissions arising due to use of energyware also emissions of methane and other volatile organic compounds from the drilling holes are included. Crude oil emanating in drilling test is burnt, emissions are included.
Offshore exploration leads to emissions of drilling chemicals and drilling sludge to the sea, though a lot of it is cleaned on the platform before it is emitted. Other emissions to the sea are heavy metals from the drilled sea bed, oil and intraformation water. Some of the drilling chemicals and sludge is brought to the shore as waste.
Waste of onshore activities are of the same kind. It is put in landfills, land-farming or casted (emissions from these processes are included).

Extraction
Average on- and offshore extraction has been inventoried regarding construction and demolition of platforms, towers, pipelines etc., use of energyware, materials (steel and concrete) and land/sea bed.
Cleaning of crude oil from water and gas is included as well as flaring of gas, leaks, blow-outs and low pressure venting (emissions of mercury and radioactive radon are accounted for since these elements are found in the gas).
Different methods of energyware demanding pumping processes are needed when the pressure in the oil source is too low to allow oil from emanating by itself. Water can be pumped into the oil source or gas recovered from the oil source can be compressed and led back into the oil source, there are also several other methods to enhance the oil gain in the extraction process (all these processes are included).
Production chemicals, for ex. anticorrosives, and drilling chemicals as well as emissions of those chemicals are included.
Onshore, 90% of the intraformation water is assumed to be pumped into hollows deep in the ground the rest is led into a fresh water recipient. Offshore 100% of the intraformation water is emitted to the sea.
Shipping of supplies is included.
Production waste consist of scale i.e. mineral deposits in equipment and pipelines. Scale is low level radioactive.
Dismantling process of oil platforms is not included and the whole platform including drillhole mantelings and pipelines is assumed to be deposited, i.e. no recycling.

Long-distance transports
The average transport situation has been scanned. Transports with pipeline (on- and offshore), tanker, train, barge and lorry have been taken into account. Construction, demolition and maintenance of infrastructure (vehicles, pipelines, ships) has been included as well as energyware consumption (extraction included), emissions and waste. Electricity consumption and land use of harbours is included.
Losses due to vapourization of oil have been taken into account. Oil emissions due to regularly occurring leaks in pipelines and smaller accidents etc. are included.

Refineries
The major part of oil products consumed in Europe are refined in Europe.
Following processes in refineries have been studied: 1. desalination, 2. distillation, 3. coking (cracking process), 4. visbreaking (lowering of viscosity), 5. hydrotreating (cleaning from e.g. sulphur), 6. catalytic cracking, 7. hydrocracking, 8. catalytic reforming, 9. isomerization, 10. alkylation, 11. steamreforming and 12. steamcracking. Losses due to flaring of refinery gas is included.
Following are the products of the studied refineries: refinery gas, propane and butane, petrol (leaded and unleaded) and naphtha, kerosene and diesel, light oil, heavy oil and bitumen. The products interesting for power plants are light and heavy oil, emanating from successive processes 1,2,4,5,6.
The use of additives in certain oil products have been scanned and included as organic chemicals.
Resource consumption, emissions and waste in connection with construction, demolition and use of operation chemicals and catalysts of refineries have mostly been gathered from literature. Operation parameters regularly meassured - water and energyware consumption, emissions of SO_2, NO_x, HC and oil to water, waste etc. - have been received from European refineries. For other parameters only a few occasional values were available. For refineries in the former Soviet Union only specific data concerning VOC-emissions and use of energyware were available, for the rest European figures have been used.

Regional distribution
Transport of fuel from refinery to power plant is assumed to be a 100 km train transport.

Power plant
Only base load plants, > 100 MWe, fired with heavy fuel oil (average lower heating value 40 MJ/kg, density 1 kg/l, sulphur concentration 2,4 % by weight) are inventoried. Only common flue gas cleaning equipment have been regarded, de-NO_x equipment (SCR and primary measures), sulphur cleaning equipment (REA) and particle filters (textile).
Data concerning operation emissions of SO_2, NO_x and particles have been received from

	statistics of the different UCPTE* countries but for other parameters mostly default values from literature have been used. Chemical use for cooling water treatment and emissions to water are included (general data for all kinds of thermal power plants). Operation data from German power plants has been used regarding wastes. Net efficiency of power plants has been calculated on basis of country specific information and the UCPTE* average came to be 38%. Construction and demolition data has been determined based on data for a stone coal power plant and specific data for oil-fuelled power plants. Following assumptions have been made for the construction phase: base load plant, net efficiency 38%, lifetime 30 years, operation time 5700 h/year. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.

System Boundaries

Nature Boundary	Used materials and energyware have been followed from extraction and processing of natural resources. Maufacturing processes for the use of recycled material are accounted for. Emissions from energyware use in manufacturing processes and transports (infrastructure and vehicle construction included) are considered as well as emissions from landfills (infrastructure included) where waste material is disposed of. Waste material supposed to be recycled are outputs of the system (i.e. those recycling processes are not included). Land is divided into two main groups - land and sea - which are subdivided into 4 categories each. Land Criterion Category Natural human impact not larger than other species' since the industrial revolution I Modified human impact larger than other species', low degree of cultivation II Cultivated human impact larger than other species', large degree of cultivation III Built upon dominated by buildings, roads, dams, mines etc. IV Category I is not used in the study. State of land before, during and after exploitation is of interest. If a piece of land is used again after some kind of exploitation it will either end up in the same category or in a higher one. ETH takes into account not only the land used during the technical lifetime of the studied system but also during the construction phase and during the time it takes to restore the land. They express use of land in the unit m2year which is different from comparable Swedish studies (m2). See times for restoration of land below: From category IV to category III 5 years From category III to category II 50 years From category II to category I 100 000 years (For uranium mines the restoration time to category II is 80'000 years due to elevated radiation caused by long-living radioactive compounds.) ETH's LCI-results comprise all parameters received during inventory and calculation, i.e. no selection has been made by ETH.
Time Boundary	The figures describe the average operation of studied plants in 1994. But for the flue gas cleaning plant data from 1994/95 have been used. Most of the data used to describe exploration and extraction of oil is younger than 1985. Figures concerning other fuel extraction and processing represent an average of the early nineties. Descriptions and figures of different technical processes come from literature, contractors, public and private institutions and describe the situation of the late eighties. Electricity used during the lifecycle has been assumed to be a mix based on the average generation in the UCPTE* countries between 1990-94 (to level off the large variations in hydro power production over the years). All processes, also those conducted in the past, have been assumed to use average technology of the early nineties. Different technical lifetimes/reference times for different parts and materials of the studied systems have been used as follows: Pipelines 30 years Tanker 24 years Barge 30 years Power plant 30 years * Union pour la coordination de la production et du transport de l'életricité, following

	countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Geographical Boundary	The world has been devided into 7 supply regions for oil: The Middle East, Latin America (including Mexico), North and Central Africa, Europe, former Soviet Union and North America. The European harbours have been grouped into two regions: North Sea Region and the Mediterranean Region. Crude oil from the Middle East, discharged in the Mediterranean harbours, is assumed to pass through the Suez Channel while Middle East oil, discharged in the North Sea Region is supposed to pass Cape Hope. Refinery locations have been devided into three categories: Switzerland, Western Europe and former Soviet Union. Refineries in North America and Africa are assumed to keep the same standard as refineries in Europe. Two refineries in western Europe have been inventoried and one refinery on the border between Poland and German has been studied, the latter based on literature information. Processes conducted outside the UCPTE* region are supposed to be supplied with UCPTE* electricity. Data concerning the use of resources, emissions and waste in connection with manufacturing processes mainly originate from sources in Switzerland, Germany and other western European countries. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.
Other Boundaries	Manufacturing processes of components and machines have been approximated with 50% of the energyware used to produce contained materials. Energyware figures concerning material production come from literature and have assumed to be a mix of 10% UCPTE electricity, 45% oil and 45% natural gas. This approximation has been confirmed in more thorough calculations in ETH's LCA for coal power. Big accidents occuring seldomly are not included.The threshold is fixed at 10 accidents per year if one energy carrier/system (e.g. oil) would cover the entire primary energy demand of the world.
Allocations	Allocations have been made with respect to lower heating value or weight. Allocation of flaring and blow-out losses as well as other losses was done with respect to the lower heating value of the two commercialized products: crude oil and natural gas. Other environmental impact in the exploration and extraction phase were allocated to crude oil since only a small part of the natural gas extracted together with crude oil is commercialized. In the refinery, allocation was done in accordance with weight of the oil products in the different subprocesses. The cutoff-method has been used for material use, i.e. 100% of the environmental load for virgin and recycled material used in the lifecycle is included whereas no environmental load has been considered for materials leaving the system to be recycled. Landfill processes and waste incineration, however, are included for waste arising during the lifecycle.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1985 to 1995
Data Type	Derived, unspecified
Represents	Average electricity generation with oil (larger plants) in the UCTPE countries.
Method	The figures have been copied from the module ''Electricity oil thermal UCPTE'' (Strom oelthermisch, UCPTE) in the Ökoinventare von Energiesystemen, ETH Zürich 1996.
Literature Reference	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz, Environmental Life-Cycle Inventories of Energy Systems An Environmental Database for the Accounting of Energy Consumption in Product Life-Cycle Assessment and the Comparative Assessment of Energy systems Prof. Dr. P. Suter, R. Frischknecht, et al Swiss Federal Institute of Technology, Zürich R. Dones, U. Gantner Paul Scherrer Institute, Villigen/Würenlingen
Notes	Multiple flows are reported for several emissions to air. This is because that in the original study emissions to air have been reported in three categories, indicated by one of the letters below following the substance name. - m = mobile (emissions from vehicles) - p = process (process specific emissions as for instance methane emissions during coal mining) -

	s = stationary (emissions from stationary combustion plants) This categorisation has however not been documented in this specification in the SPINE format.

About Inventory	
Publication	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz. ETH, Eidgenössische Technische Hochschule, Zürich, Gruppe Energie - Stoffe - Umwelt (ESU), Paul Scherrer Institut, Villigen/Würenlingen, Sektion Ganzheitliche Systemanalysen Available on CD-ROM with full documentation (in German) at http://www.energieforschung.ch. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by (see also Notes): Rolf Frischknecht, ESU-services, Switzerland Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	Original study of ETH: LCA pra
General Purpose	The purpose of the ETH study was to examine a number of energy systems quantitatively and to the same extent with respect to environmental issues during their lifecycles. The results can be used in lifecycle assessments, as basis information in decisionmaking regarding environmental optimisation or in working with municipal energy plans.
Detailed Purpose	ETH:s aim was to describe the average situation in UCPTE concerning electricity generation with oil. With the help of assumptions and simplifications following phases of the life cycle are described: exploration (on- and offshore) extraction (on- and offshore), long-distance transports, refinery, distribution and power plant.
Commissioner	BEW, PSEL - Bundesamt für Energiewirtschaft, Projekt- und Studienfonds der Elektrizitätswirtschaft .
Practitioner	Rolf Frischknecht et al - ETH, Eidgenössische Technische Hochschule, Institut für Energietechnik, Zürich and Paul Scherrer Institut, Sektion Ganzheitliche Systemanalyse, Villingen/Würenlingen .
Reviewer	None, see further under notes -
Applicability	Data reported here is supposed to be representative for oil electricity generation in the UCPTE countries in 1994.
About Data	Material manufacturing processes have been inventoried with a low degree of exactitude (except for steel, cement, aluminium, copper, bitumen, and platinum group metals for which rather detailed LCI data are provided). Results are reported with three figures, but it is stated in the original source that this does not mean that accuracy is that high (Part III, p.16). For references and sources of reported figures see further under Function, Nature boundary, Geographical boundaries, Publication, Notes and General metadata.

SPINE LCI dataset: Oil filter combustion

Administrative	
Finished	Y
Date Completed	2002-12-12
Copyright	
Availability	Public

Technical System	
Name	Oil filter combustion
Functional Unit	0.706 kg of filter
Functional Unit Explanation	The oil filter HC 8904 FKP 16Z weighs 0.706 kg.
Process Type	Gate to grave
Site	Kumla
Sector	
Owner	Kumla
Technical system description	This activity describes oil filter combustion. The oil filters are used to clean circulating oil in a lubricant system. After use, the filters are disposed and burned as waste. Energy is co-produced and total combustion is assumed.

System Boundaries	
Nature Boundary	The filters come from the technospere. The combustion gives emissions to air.
Time Boundary	Data is collected autumn 2002. No changes are planned for the nearest future.
Geographical Boundary	The combustion is performed in Kumla, Sweden.
Other Boundaries	No transports are included.
Allocations	Not applicable
Systems Expansions	Not applicable

Flow Data	
General Activity QMetaData	
Date Conceived	2002-11-29 - 2002-12-31

About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Thechnology, December 2002 -------------- Data documented by Sandra Häggström, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-03-21.
Intended User	Product developer at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The purpose for our study is to compare a coated roller bearing to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll and is lubricated with a circulating oil system in both cases. The circulating oil is cleaned using filters from Pall, also in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Sandra Häggström - .
Reviewer	Olle Ramnäs -
Applicability	The data is applicable for coreless oil filters.
About Data	The data is collected by personal communication with Annika Lorin at SAKAB and Mike Day, Pall Corporation. Information about molecular formulas are taken from www.polymerprocessing.com.
Notes	

SPINE LCI dataset: Operation of 'Hot Dogs' producing facility. ESA-DBP

Administrative

Finished	Y
Date Completed	2005
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System

Name	Operation of 'Hot Dogs' producing facility. ESA-DBP
Functional Unit	1 year of operation of the facility
Functional Unit Explanation	All data originate from the mandatory environmental report that Swedish companies present each year, and they are the cumulative numbers for one year for the whole facility. (NB: no information about the annual volume of production)

Process Type	Gate to gate
Site	Unknown
Sector	Food products and beverages
Owner	Unknown
Technical system description	Excerpt from the report, see 'Publication': ''In co-operation with Swedish Meats, a production facility in Örebro, Sweden, was studied. The reason for choosing the particular facility was that it mainly produces one product, named 'Hot Dogs'. (...) The main production process consists of eight processes, of which some may be divided into two or more steps: (...) 1. Grinding - Frozen products are thawed before use. The meat ingredients are ground, and an automatic device is used to supervise the fat content. 2. Pre-mixing - the meat mixture is mixed with water, ice, and salt. 3. Ripening in silo - storage of meat mixture, usually for 1-5 days. Six silos, each with a capacity of 12 tonnes. 4. Recipe mixing - mixing of meat mixture with other ingredients, such as potato starch and spices. A highly automated process, where the operator just defines the amounts, after which the mixture is prepared by the machine. 5. Extruding - four extruding machines, which are loaded with cellulose tubes. The sausage batter is extruded through the tubes at high speed, whereupon casing-covered sausages are formed. The cellulose casing is manufactured by Viscofan SA in Pamplona, Spain. Long strings of sausages are then cooked, smoked and cooled down. 6. Peeling of sausage strings - four parallel machines use steam to peel the casing off the sausages. 7. Packaging - six packaging lines with various capacity, each including several steps: positioning, vacuum packaging (big rolls of plastic wrapping are heat-moulded into shape, sausages are inserted, and the packages are sealed), scale/metal detector, (defective products are removed), picker (a fast robot loads the packages into plastic trays), robot loading trays on pallet. 8. Loading area - facility office; stock input to logistics software, and back-reporting of customer orders. This process is included in the system described in: Abelmann A. (2005). Environmental Potential of Increased Human Consumption of Grain Legumes. An LCA of food products. Master thesis. ESA report 2005:10, ISSN: 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2005--10.pdf Other processes in the CPM Database also included in the above publication: - Sausage (Soy-Dog) production. ESA-DBP - Sausage (Pea-Dog) production. ESA-DBP - Sausage (Hot-Dog) production. ESA-DBP - Pea cultivation. ESA-DBP - Production of beef. ESA-DBP - Production of pork. ESA-DBP - Rape seed cultivation. ESA-DBP - Wheat cultivation. ESA-DBP - Sugar beet cultivation. ESA-DBP - Soy bean processing. ESA-DBP - Soy bean cultivation. ESA-DBP

System Boundaries

Nature Boundary	The data relate only to the operation of the production facility. It includes energy use, emissions to water, water use, chemical consumption and waste generation.
Time Boundary	The data were acquired from the report for the year 2005.
Geographical Boundary	The facility is located in Örebro, Sweden.
Other Boundaries	The facility produces mainly only 1 product 'Hot Dogs'.
Allocations	The data was given per 1 year.
Systems Expansions	Not applicable

Intended User	LCA practitioner
General Purpose	Excerpt from the report, see 'Publication': ''The overall aim of the study is to assess the potential environmental impacts of substituting animal protein for regionally grown vegetable protein in food products.''
Detailed Purpose	Excerpt from the report, see 'Publication': ''The objective is to analyze three food products of the same type, and the purpose is to compare the environmental impact of the products and also to identify the most important contributors of the total environmental impact of each product. The products are described as follows. - a product in which all protein is animal protein. - a product in which 10% of the animal protein is replaced with vegetable protein. - a product in which all protein is vegetable protein. Furthermore, the objective is to provide useful information on the products that can be used in other environmental systems analysis, e.g. in meal studies.

Technical System	
Name	Operation of large scale waste water treatment plant. ESA-DBP
Functional Unit	person·year
Functional Unit Explanation	These flows were normalized to the functional unit which is treatment of the sewage from one person-equivalent during one year. The person-equivalent is a fictitious person who spends all his or her time in Kronan.
Process Type	Gate to grave
Site	Building area 'Kronan', Luleå
Sector	Waste treatment
Owner	Building area 'Kronan', Luleå
Technical system description	The study was performed for the projected housing area Kronan in Luleå, a city in Northern Sweden. The system was designed for the area that accomodates 2700 inhabitants and provides workspace for 1000 people. Excerpt from the report, see 'Publication': In the conventional system, all sewage from the housing area would be pumped to the existing Uddebo Waste Water Treatment Plant (WWTP), which currently serves 72000 person equivalents (pe). The estimated reduction rates of a process including chemical precipitation with ferric chloride and a projected biological treatment step (without nitrification) were 95% for phosphorus and biological oxygen demand (BOD) and 30% for nitrogen. It was estimated that the sludge from the treatment plant would contain 95% of incoming phosphorus and 18% of the incoming nitrogen. The sludge would be stored 6-12 months before being transported by truck to farms on an average distance of 25 km from Luleå and applied as fertilizer. This process is included in the system described in: Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/TEP_1997--9.pdf Other processes in the CPM Database also included in the above publication: Operation of waste water treatment plant with urine and sludge separation . ESA-DBP Operation of the sewage sludge and septage treatment system - local treatment option. ESA-DBP Operation of the sewage sludge and septage treatment system - central treatment option. System Boundaries

Nature Boundary	The inventory analysis included parameters describing resource use (energy and raw materials) emissions to air, emissions to water, and waste generation.
Time Boundary	The data were acquired in 1997 as the most up-to-date ones. It is assumed that the results should be valid for at least 10 years.
Geographical Boundary	The study was done for Luleå, Sweden.
Other Boundaries	The LCA base model included the collection, treatment, and transportation of wastewater as well as the production of chemicals and other materials required to operate the system. Excerpt from the report, see 'Publication': ''The heating of water has not been included in the analysis since it has been assumed that there will be no difference between the alternatives in the consumption of hot water. For the sake of making a complete description of the technical systems and an analysis of the environmental impact of these systems, it might have been included. In the analysis only the environmental impacts the households cause via the sanitary systems have been regarded. Other environmental impacts of the households have been regarded as irrelevant in this study. The treatment of storm water has not been included in the study. In both alternatives, storm water will be taken care of separately and, consquently, it will not affect the flows of sewage and urine.''
Allocations	No information about the allocation process.
Systems Expansions	Not applicable

Technical System	
Name	Operation of liquid composting batch process. ESA-DBP
Functional Unit	person·year
Functional Unit Explanation	The functional unit chosen is the treatment of one persons sewage and organic waste during one year. The sewage treatment includes black water and grey water.
Process Type	Gate to grave
Site	WWTP in Horn, Sweden
Sector	Waste treatment
Owner	WWTP in Horn, Sweden
Technical system description	Liquid composting batch process was one of the options considered for a little village Horn in the municipality of Västerås, which is a small, planned village of 200 inhabitants situated in a rural area in central Sweden. The other options were: liquid composting continuous process and conventional waste water treatment plant. The main function of the discussed solution is to treat the toilet and organic kitchen waste. In this solution (excerpt from the report, see 'Publication') ''toilet and kitchen waste is treated batchwise in a liquid composting tank. (...) Grey water (bath, shower and laundry) is treated separately in a sludge separator, filter beds and open ditches. The liquid composted sludge and the filter bed sand are spread on agricultural land. Liquid composting is an aerobic thermophilic digestion where organic material is stabilised in a reactor by adding enough air to induce aerobic degradation which increases the temperature. Ideally, the sludge should contain at least 3% solids and therefore conventional toilets can not be used, since they need too much water. In order to reach the high temperature (60-65 °C) the reactor needs to be well insulated and organic kitchen waste is mixed with the black water to increase the energy content. The mixture has a resident time of 7 days in the reactor. After treatment, the compost sludge is pumped to a storage tank and after a period of 6 months to one year ready to be spread on farmland.'' The raw sludge consists of black water and flush water, kitchen waste and the septage from a septic tank which is a part of the grey water treatment. The batch system consists of a buffer tank and collection tank. The treatment takes place in the storage tank, similar to the collection tank where the sludge is aerated once a year for about one month. ''Considering the operation, the batch process is less electricity consuming. In the compost organic material is converted to CO_2 and nitrogen is released to air as NH_3. To avoid odour and ammonia emissions the air from the reactor needs to be treated before it is released to the atmosphere. This treatment consists of a condensation step where most of the ammonia is condensed and returned to the reactor, followed by a biofilter (peat) where the rest of the ammonia can be either bound to the peat, transformed to nitrogen gas or released unaffected. (...) It is assumed that all nitrogen is captured in the peat and returned to agriculture. Further it is also assumed that small quantities of CH_4 and N_2O which might be produced in the compost are eliminated in a well-functioning biofilter. The peat is changed twice every year and used as fertiliser. In a full-scale system it is likely that some nitrogen will pass the biofilter as N_2 or NH_3, these assumptions are therefore believed to be slightly optimistic.''

	This process is included in the system described in: Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/TEP_1997--9.pdf Other processes in the CPM Database also included in the above publication: Operation of waste water treatment plant with urine and sludge separation . ESA-DBP Operation of the sewage sludge and septage treatment system - local treatment option. ESA-DBP Operation of the sewage sludge and septage treatment system - central treatment option. ESA-DBP Operation of small-scale waste water treatment plant. ESA-DBP Operation of liquid composting continuous system. ESA-DBP Operation of large scale waste water treatment plant. System Boundaries

Nature Boundary	Excerpt from the report, see 'Publication': ''The operation of the system concerns first of all the emissions to Lake Freden part of Lake Mälaren. But the operation also has impacts on a larger scale, such as emissions of gaseous pollutants and materials produced in other regions.''
Time Boundary	The data were acquired in 1997 as the most up-to-date ones. Excerpt from the report, see 'Publication': ''The study is made for a wastewater system in a village planned to be built in one or two years. The components of the sanitary system are assumed to have a life time of 15 to 30 years.''
Geographical Boundary	The study was done for the village Horn, Sweden. In the construction analysis it is assumed that most of the equipment is made in Sweden, Norway or Finland.
Other Boundaries	Excerpt from the report, see 'Publication': ''The study includes the handling of wastewater and organic (compostable) kitchen waste, but not other types of waste such as glass, plastics, paper or metals. Furthermore distribution and treatment of drinking water and collection of stormwater are not included in the study. These will be the same for the two alternatives and will not contribute to differences in the comparison. Included in the system are the collection, treatment and transportation of waste and wastewater, and the spreading of nutrients on agricultural land. The production of chemicals and other types of 35 materials needed are included as well as production of electricity and avoided artificial fertiliser. The transportation of the material is not included in the analysis. (...) According to the detailed development plan, 57 houses are to be constructed in the property of Horn in Västerås municipality.''
Allocations	No information about the allocation process.
Systems Expansions	Not applicable

Technical System	
Name	Operation of liquid composting continuous system. ESA-DBP
Functional Unit	person·year
Functional Unit Explanation	The functional unit chosen is the treatment of one persons sewage and organic waste during one year. The sewage treatment includes black water and grey water.
Process Type	Gate to grave
Site	WWTP in Horn, Sweden
Sector	Waste treatment
Owner	WWTP in Horn, Sweden
Technical system description	Liquid composting continuous process was one of the options considered for Horn in the municipality of Västerås, which is a small, planned village of 200 inhabitants situated in a rural area in central Sweden. According to the detailed development plan, 57 houses are to be constructed in this area. The other considered options for this area were: liquid composting batch process and conventional waste water treatment plant. The main function of the discussed solution is to treat the toilet and organic kitchen waste. In this solution (excerpt from the report, see 'Publication') ''toilet and kitchen waste is treated continuously in a liquid composting reactor. Grey water (bath, shower and laundry) is treated separately in a sludge separator, filter beds and open ditches. The liquid composted sludge and the filter bed sand are spread on agricultural land. Liquid composting is an aerobic thermophilic digestion where organic material is stabilised in a reactor by adding enough air to induce aerobic degradation which increases the temperature. Ideally, the sludge should contain at least 3% solids and therefore conventional toilets can not be used, since they need too much water. In order to reach the high temperature (60-65 °C) the reactor needs to be well insulated and organic kitchen waste is mixed with the black water to increase the energy content. The mixture has a resident time of 7 days in the reactor. After treatment, the compost sludge is pumped to a storage tank and after a period of 6 months to one year ready to be spread on farmland. (...) The raw sludge consists of black water and flush water, kitchen waste and the septage from a septic tank which is a part of the grey water treatment. Totally 420m3 raw sludge is estimated to be treated yearly. The continuous system consists of a buffer tank and an insulated reactor. An aeration system supplies the reactor with air and mixes the liquid. The electricity demand for aeration and mixing is according to Alfa Laval Agri 30kWh/m3 mixture. The heat from the reactor could be used e.g. for heating the building but is not included in the analysis. In the compost organic material is converted to CO_2 and nitrogen is released to air as NH_3. To avoid odour and ammonia emissions the air from the reactor needs to be treated before it is released to the atmosphere. This treatment consists of a condensation step where most of the ammonia is condensed and returned to the reactor, followed by a biofilter (peat) where the rest of the ammonia can be either bound to the peat, transformed to nitrogen gas or released unaffected. (...) It is assumed that all nitrogen is captured in the peat and returned to agriculture. Further it is also assumed that small quantities of CH_4 and N_2O which might be produced in the compost are eliminated in a well-functioning biofilter. The peat is changed twice every year and used as fertiliser. In a full-scale system it is likely that some nitrogen will pass the biofilter as N_2 or NH_3, these assumptions are therefore believed to be slightly optimistic.'' This process is included in the system described in: Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/TEP_1997--9.pdf Other processes in the CPM Database also included in the above publication: Operation of waste water treatment plant with urine and sludge separation . System Boundaries

Nature Boundary	Excerpt from the report, see 'Publication': ''The operation of the system concerns first of all the emissions to Lake Freden part of Lake Mälaren. But the operation also has impacts on a larger scale, such as emissions of gaseous pollutants and materials produced in other regions.''
Time Boundary	The data were acquired in 1997 as the most up-to-date ones. Excerpt from the report, see 'Publication': ''The study is made for a wastewater system in a village planned to be built in one or two years. The components of the sanitary system are assumed to have a life time of 15 to 30 years.''
Geographical Boundary	The study was done for the village Horn, Sweden. In the construction analysis it is assumed that most of the equipment is made in Sweden, Norway or Finland.
Other Boundaries	Excerpt from the report, see 'Publication': ''The study includes the handling of wastewater and organic (comparable) kitchen waste, but not other types of waste such as glass, plastics, paper or metals. Furthermore distribution and treatment of drinking water and collection of stormwater are not included in the study. These will be the same for the two alternatives and will not contribute to differences in the comparison. Included in the system are the collection, treatment and transportation of waste and wastewater, and the spreading of nutrients on agricultural land. The production of chemicals and other types of 35 materials needed are included (...). The construction does only include the environmental impacts due to the production of the material and not the use, reuse or disposal of the equipment. (...) The transportation of the material is not included in the analysis. (...) According to the detailed development plan, 57 houses are to be constructed in the property of Horn in Västerås municipality.'' Production of electricity is excluded from the study.
Allocations	No information about the allocation process.

Technical System	
Name	Operation of small-scale waste water treatment plant. ESA-DBP
Functional Unit	person·year
Functional Unit Explanation	The functional unit chosen is the treatment of one persons sewage and organic waste during one year. The sewage treatment includes black water and grey water.
Process Type	Gate to grave
Site	WWTP in Horn, Sweden
Sector	Waste treatment
Owner	WWTP in Horn, Sweden
Technical system description	Small waste water treatment process was one of the options considered for a little village Horn in the municipality of Västerås, which is a small, planned village of 200 inhabitants situated in a rural area in central Sweden. The other options were: liquid composting continuous process and liquid composting batch process. Excerpt from the report, see 'Publication': In the (...) WWTP, all wastewater is treated in a small wastewater treatment plant consisting of mechanical, biological and chemical steps. The organic kitchen waste is treated separately in a common drum compost. After storage the sludge is spread on agricultural land while the compost is used in the residents' gardens. (...) In the households water saving toilets are installed with two different volumes: small flush (urine) 2 litres, and big flush (faeces) 4 litres. It is estimated, using the assumptions above that one person uses 14 litres of water per day for flushing. The treatment includes a biological and a chemical step. It is a batch process with two modules which are supplied from one receiving tank. Each of the modules goes through a cycle of five phases; filling, aeration, sedimentation, emptying and pausing. Excess sludge is pumped to the sludge tank. Iron chloride (PIX 111) is added as a precipitation chemical and oxygen for the biological process is supplied by two aerators. The whole treatment process is regulated by a computer (not included in the analysis). (...) Before the treated wastewater is released to the recipient it is disinfected with ultraviolet light to destroy pathogens. The water is led through a contact basin where UV lamps are installed. As a source of UV radiation mercury lamps are used. The electricity demand of the disinfection is included in the analysis but not 43 the construction of the UV-basin nor is the production and disposal of mercury lamps, hereby assuming that no leakage of mercury will occur. (...) Kitchen waste is ground and composted in a local drum compost. The mixture is aerated and mixed in the rotating drum. To achieve a favourable carbon-nitrogen quota wooden chips should be added. Most of the organic material is converted to carbon dioxide and it is assumed that about 20% of the nitrogen is released to the air, half as ammonia and half as nitrogen gas. The drum compost is placed in a building identical to the sewage plant building (included in the analysis). The composted product is stored there until the residents use it in their gardens. (...) The plant is placed in a building (35 m^2) which is included in the analysis. The sludge from the process is pumped to a concrete storage tank (100 m^3). The tank is underground, covered and the sludge is mixed to avoid emissions of NH_3, CH_4 and odour. Sewage sludge is stored up to one year before it is spread on arable land.'' This process is included in the system described in: Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. Technical System	
Name	Operation of the sewage sludge and septage treatment system - central treatment option. ESA-DBP
Functional Unit	1 m3 of handled raw sewage sludge
Functional Unit Explanation	Excerpt from the report, see 'Publication': ''the functional unit chosen is the handling of one m^3 of raw sewage sludge. The handling include thickening, stabilisation, transports and spreading to agricultural land. (A rough estimation is that 1 m^3 sludge correspond to 2 person equivalents).''
Process Type	Gate to grave
Site	Koster islands, Strömstad, Sweden
Sector	Waste treatment
Owner	Koster islands, Strömstad, Sweden
Technical system description	Central treatment of sewage sludge and septage is an option for the Koster islands in the municipality of Strömstad. Excerpt from the report, see 'Publication': ''The municipality of Strömstad is planning to build a common sewer system for the two islands, increase the capacity of the sewers and construct a wastewater treatment plant. The sludge from the sewage plant and the septage from the individual septic tanks will be treated either locally on the islands or transported to Strömstad. The estimated future capacity is that 400 persons on average will be connected to the planned sewage plant and about 300 septic tanks (corresponding to an average of 1000 persons) will be emptied and the septage treated. It is estimated that the amount of sludge from the central septic tank will increase to 200 m^3 per year when the sewage plant is built.'' The general flow starts with treatment of supernatant which is followed by sludge transportation to the thickening mechanism. In parallel septage is prepared and transported to this mechanism as well. After this step liquid compost is transported to Strömstad Waste Water Treatment Plant where is dewatered, stored and then spread near Strömstad area. Excerpt from the report, see 'Publication': ''The sewage plant chosen is a rotating biological contactor from Klargester called Biodisc. The Biodisc, consist of two discs, one will be operating during winters and two during summers. (...) After treatment the treated wastewater will be led to a system of ditches and wetlands and the water can be used for irrigation during the summer. The wastewater is first led to a primary settlement and then to the biological step. The biological treatment consist of the rotating discs where the wastewater is aerated. On the large areas of the discs biomass is grown. Suspended biomass is led to the primary settlement and to the final settlement. Excess sludge is pumped from the final settlement and transported to a storage tank. Iron chloride is added as a precipitation chemical by a dosage pump. The septage is collected by trucks during two weeks before the summer season. The septic tanks have a volume of ca 4m^3 and are emptied every second year which means that 600 m^3 sludge is collected every year. The dry solid content (DS) is low, about 1%. The pumper truck has a volume of 12m^3. According to SNV 87:6 a well-designed and maintained septic tank can separate the suspended material by ca 70 % but the reduction of nutrients is low; 10-20%. (...) Thickening is the procedure used to increase the solid content of the sludge by removing the liquid fraction. Paper and grit is separated from the septage before thickening by a screen bar and collected together with the sewage grit in a container. (...) The thickener consist of a rotating drum. Polymer is added to the raw sludge which is led through the drum by the rotation and the slope of the drum and the water is drained through a sieve cloth. The sieve cloth is not included in the LCA. The thickened sludge is led to a storage tank and the liquid fraction is returned to the sewage plant. It is estimated that all of the phosphorus and BOD is bound to the sludge while half of the nitrogen content in

	septage and sludge is dissolved to the liquid and hence is returned to the sewage plant. The sludge is thickened to a DS-content of 5%. (...) In the central treatment alternative the sludge is thickened as described above before transportation to a central treatment plant in Strömstad. There the sludge is received and mixed with the Strömstad sewage sludge before it is dewatered in a centrifuge. The Strömstad sewage plant is operated as an extended aeration process which give some stabilisation. The external sludge from Koster is not subjected to any stabilisation other than storage which means that the risk of contamination from the sludge is higher than in the first alternative. The supernatant from the dewatering is led to the biological treatment. As in the thickening process it is assumed that all of the phosphorus and BOD is bound to the sludge while half of the nitrogen is dissolved to the liquid and returned to the Strömstad sewage plant. The supernatant correspond to a very low percentage of the total flow to the treatment plant. Therefor it is assumed that the electricity demand due to the treatment of the supernatant is negligible. After the centrifugation (where polymer is added) the sludge has a DS-content of 15%. All of the sludge is assumed to be spread on agricultural land on a average distance of 25 km from Strömstad.'' This process is included in the system described in: Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/TEP_1997--9.pdf Other processes in the CPM Database also included in the above publication: Operation of waste water treatment plant with urine and sludge separation . ESA-DBP Operation of the sewage sludge and septage treatment system - local treatment option. ESA-DBP Operation of small-scale waste water treatment plant. ESA-DBP Operation of liquid composting continuous system. ESA-DBP Operation of liquid composting batch process. ESA-DBP Operation of large scale waste water treatment plant. System Boundaries	
Nature Boundary	The sludge is collected in the households and processed. The output is mainly compost which can be useful in agriculture. The system studied can also have impacts on a larger scale such as emissions of gaseous pollutants, use of energy and chemicals produced in other regions e.g. phosphorus mining.
Time Boundary	The data were acquired in 1997 as the most up-to-date ones. The sanitary system is planned to be built in 1998 and will operate for some decades.
Geographical Boundary	Excerpt from the report, see 'Publication': ''The operation of the wastewater system is limited to the islands of Koster and the city of Strömstad with its close surroundings. However the contaminants from the system can have effects on a larger area.''
Other Boundaries	Excerpt from the report, see 'Publication': ''The study only includes the treatment of sewage sludge and septage, not other types of solid waste. The wastewater treatment is partly included, namely the part that involves the 63 liquid fraction which remains after thickening (supernatant) and not the ordinary treatment of wastewater. Another limitation is that the LCA only includes the operation of the system, not the construction. The production of electricity is included in the analysis and is calculated as average Swedish electricity. The production of polymer and avoided production of fertiliser are also included. The use of fossil fuels such as gas, oil and coal are considered in the system but not the refining or extraction of the resources. (...) The estimated future capacity is that 400 persons on average will be connected to the planned sewage plant and about 300 septic tanks (corresponding to an average of 1000 persons) will be emptied and the septage treated. It is estimated that the amount of sludge from the central septic tank will increase to 200 m^3 per year when the sewage plant is built.'' NB: the results presented in CPM do not include electricity nor avoided production of fertiliser.
Allocations	No information about the allocation process.

Technical System	
Name	Operation of the sewage sludge and septage treatment system - local treatment option. ESA-DBP
Functional Unit	1 m3 of handled raw sewage sludge
Functional Unit Explanation	Excerpt from the report, see 'Publication': ''the functional unit chosen is the handling of one m³ of raw sewage sludge. The handling include thickening, stabilisation, transports and spreading to agricultural land. (A rough estimation is that 1 m³ sludge correspond to 2 person equivalents).''
Process Type	Gate to grave
Site	
Sector	Waste treatment
Owner	
Technical system description	Local treatment of sewage sludge and septage is an option for the Koster islands in the municipality of Strömstad. Excerpt from the report, see 'Publication': ''The municipality of Strömstad is planning to build a common sewer system for the two islands, increase the capacity of the sewers and construct a wastewater treatment plant. The sludge from the sewage plant and the septage from the individual septic tanks will be treated either locally on the islands or transported to Strömstad. The estimated future capacity is that 400 persons on average will be connected to the planned sewage plant and about 300 septic tanks (corresponding to an average of 1000 persons) will be emptied and the septage treated. It is estimated that the amount of sludge from the central septic tank will increase to 200 m³ per year when the sewage plant is built.'' The general flow starts with treatment of supernatant which is followed by sludge transportation to the thickening mechanism. In parallel septage is prepared and transported to this mechanism as well. After this step liquid compost is stored and then spread in Koster areas. Excerpt from the report, see 'Publication': ''The sewage plant chosen is a rotating biological contactor from Klargester called Biodisc. The Biodisc, consist of two discs, one will be operating during winters and two during summers. (...) After treatment the treated wastewater will be led to a system of ditches and wetlands and the water can be used for irrigation during the summer. The wastewater is first led to a primary settlement and then to the biological step. The biological treatment consist of the rotating discs where the wastewater is aerated. On the large areas of the discs biomass is grown. Suspended biomass is led to the primary settlement and to the final settlement. Excess sludge is pumped from the final settlement and transported to a storage tank. Iron chloride is added as a precipitation chemical by a dosage pump. The septage is collected by trucks during two weeks before the summer season. The septic

	tanks have a volume of ca 4m³ and are emptied every second year which means that 600 m³ sludge is collected every year. The dry solid content (DS) is low, about 1%. The pumper truck has a volume of 12m³. According to SNV 87:6 a well-designed and maintained septic tank can separate the suspended material by ca 70 % but the reduction of nutrients is low; 10-20%. (...) Thickening is the procedure used to increase the solid content of the sludge by removing the liquid fraction. Paper and grit is separated from the septage before thickening by a screen bar and collected together with the sewage grit in a container. (...) The thickener consist of a rotating drum. Polymer is added to the raw sludge which is led through the drum by the rotation and the slope of the drum and the water is drained through a sieve cloth. The sieve cloth is not included in the LCA. The thickened sludge is led to a storage tank and the liquid fraction is returned to the sewage plant. It is estimated that all of the phosphorus and BOD is bound to the sludge while half of the nitrogen content in septage and sludge is dissolved to the liquid and hence is returned to the sewage plant. The sludge is thickened to a DS-content of 5%. (...) The raw sludge has to be stabilised to reduce pathogens and eliminate odours when the sludge is to be applied on land. In the local alternative the sludge is assumed to be stabilised in a liquid-compost after thickening. The liquid composted sludge is stored and then transported to agricultural land, in average 2 km from the sewage plant and spread by manure spreaders.'' This process is included in the system described in: Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. Technical System	
Name	Operation of waste water treatment plant with urine and sludge separation . ESA-DBP
Functional Unit	person·year
Functional Unit Explanation	These flows were normalized to the functional unit which is treatment of the sewage from one person-equivalent during one year. The person-equivalent is a fictitious person who spends all his or her time in Kronan.
Process Type	Gate to grave
Site	Building area 'Kronan', Luleå
Sector	Waste treatment
Owner	Building area 'Kronan', Luleå
Technical system description	Urine separation system is an alternative solution for a conventional waste water treatment plant. The study was performed for Luleå, a city in Northern Sweden. The system was designed for the area that accomodates 2700 inhabitants and provides workspace for 1000 people. The urine separation system requires the separation toilets to be installed. The urine water will be taken care of separately and stored in tanks. After seasonal storage of 6 months, the urine would be transported approximately 8 km and spread as liquid fertilizer. Feaces and grey water would undergo the same WWTP process as in the conventional alternative. Also in this case the sludge would be used for fertilization. The sewage system in Kronan is not built yet and according to the plans, it will be connected to the existing system in Luleå and the existing WWTP at Uddebo. The following assumptions were done: Excerpt from the report, see 'Publication': ''1. The Kronan housing area is built and all the inhabitants have moved in. 2. The Uddebo WWTP is extended with a step for biological treatment, and this new step is running in steady state. 3. Systems and routines for bringing the major part of the urine and the sludge to agricultural land are established.''

	This process is included in the system described in: Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. System Boundaries

Nature Boundary	The inventory analysis included parameters describing resource use (energy and raw materials) emissions to air, emissions to water, and waste generation.
Time Boundary	The data were acquired in 1997 as the most up-to-date ones. It is assumed that the results should be valid for at least 10 years.
Geographical Boundary	The study was done for Luleå, Sweden.
Other Boundaries	The LCA base model included the collection, treatment, and transportation of wastewater as well as the production of chemicals and other materials required to operate the system. Excerpt from the report, see 'Publication': ''The heating of water has not been included in the analysis since it has been assumed that there will be no difference between the alternatives in the consumption of hot water. For the sake of making a complete description of the technical systems and an analysis of the environmental impact of these systems, it might have been included. In the analysis only the environmental impacts the households cause via the sanitary systems have been regarded. Other environmental impacts of the households have been regarded as irrelevant in this study. The treatment of storm water has not been included in the study. In both alternatives, storm water will be taken care of separately and, consquently, it will not affect the flows of sewage and urine.''
Allocations	No information about the allocation process in the report.
Systems Expansions	Not applicable

About Inventory

Publication	Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/TEP_1997--9.pdf
Intended User	LCA practitioner, Waste Water Treatment System Specialist
General Purpose	Excerpt from the report, see 'Publication': ''The LCAs were performed on planned wastewater systems in areas within three Swedish minicipalities; Luleå, Västerås and Strömstad. Apart from the case studies a literature study of substitutability of nutriens in sewage compared to artificial fertilizers was performed.''
Detailed Purpose	Excerpt from the report, see 'Publication': ''The study has been made in order to find out the environmental consequences of two different sewage treatment alternatives for the projected housing area Kronan in the city of Luleå.(...) The major difference between the alternatives studied is that in one case the urine will be taken care of separately, while in the other the urine will be treated together with the rest of the sewage in a conventional way''

SPINE LCI dataset: Operation on desiccant cooling system - a technology in air conditioning. ESA-DBP

Administrative	
Finished	Y
Date Completed	2007
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Operation on desiccant cooling system - a technology in air conditioning. ESA-DBP
Functional Unit	1 year of operation of desiccant cooling system
Functional Unit Explanation	Energy use of disiccant cooling system operated for 1 year. Operational time is 24 hours per day.
Process Type	Gate to gate
Site	Unknown
Sector	Goods and services for households
Owner	Unknown
Technical system description	In the study the annual operating energy use during the use phase is considered. Excerpt from the report, see 'Publication': ''Desiccant cooling is an alternative technology for all-air air conditioning systems. This technique, in purpose to cool the ventilating airflow, is operated by heat and water. Hence, no ordinary refrigerant is needed. Consequently, the environmental impact due to refrigerant leakage is eliminated. Moreover, no electricity is needed for cooling the air by desiccant cooling, except of for transporting the ventilating air to and from the premises. (...) In this paper dessicant cooling refer to the combination of desiccant dehumidification and evaporative cooling for air conditioning. There are several possible ways in which such systems can be designed and there are various types of desiccant dehumidifiers that can be used for these applications. In this case, the desiccant dehumidifier concerned is a rotary dehumidifier, a desiccant wheel. The desiccant cooling system configurations studied here are not suited for controlling the indoor air humidity. The supply air humidity ratio will vary depending on the mode of operation as well as the control strategy applied. (...) In the moderately dry and cool ambient climates considered in this paper, air-conditioning primarily is used to control the indoor air temperature.''

	The main components of a desiccant cooling air handling unit are: dehumidifier, heater (regeneration coil), heat exchanger and evaporative coolers. The task of the system is ''to cool or heat a ventilating airflow of 5m3/s (100% outdoor air) to a constant supply air temperature of 17°C. The exhaust air temperature is 24°C and the exhaust air humidity ratio is 0.007 kg/kg higher than the supply air humidity ratio due to internal heat loads. Both air handling units are designed for a maximum specific fan power (SFP) of 2.4 kW/(m3/s), and the operational time is 24 hours per day during a whole year. The local climate concerned is hourly measured weather data for Stokholm, Sweden 1990. The year 1990 is chosen out of hourly measured weather data for period 1983-1992 because the number of hours with ambient air temperatures above 17°C this year is closest to the 10-year mean value. (...) The component performances are: - The supply and exhaust evaporative coolers' saturation efficiency is 80% - The sensible heat exchanger's temperature efficiency is 70% - The performance of the desiccant wheel is equivalent to a commercialy available component having a face velocity of 2.5 m/s and a rotor depth of 0.2 m. The vapour compression air-cooling process is modelled to be performed by a cooling coil with a constant surface temperature of 100°C. Graphically on a psychometric chart, in case of a wet (sensible or latent) cooling process, this means that the ambient air condition will change in the direction towards the air condition 10°C/100% RH. The evaporating temperature of the refrigerant is 15K lower than the coil surface temperature (-5°C). The condensing temperature is 15K higher than the actual ambient air temperature. Finally, the electricity use by the compressor for cooling the air is calculated hour by hour with a total Carnot efficiency of 0.5. In heating mode, a heat exchanger with the same temperature efficiency as in case of the desiccant cooling system is presumed. Consequently, the vapour compression system requires heat energy when ambient air temperature is below 0°C. The refrigerant is HFC-134a and the charge of the system is 23.5 kg. The annual leakage is assumed 2% of the charge. (...) For the DC air handling unit, electricity is needed for the transportation of the ventilating airflow. The DC-unit requires heat energy in cooling mode for the generation heater, but no heat is required during the cold period of the year due to the combined effect of heat recovery by the exchanger and the desiccant wheel. Water is used for the evaporative cooling. (...) The DC-unit consumes ca 103400 kWh of electricity for operating fans. The heat use is 7600 kWh and the water use is 730 m3 for cooling purpose.'' Main assumptions made for this study are (NB:based on the comparative table): constant airflow, total airflow 5 m3/s, supply air temperature = 17°C, exhaust air temperature = 24°C, operating time - 8760 [hours/year], SFP 2.4 [kW/(m3/s)]. This process is included in the system described in: Heikkilä K. (2007). Environmental Assessment of Air-conditioning Systems. Design Considerations for Swedish Conditions. Report no. D 2007:2, Department of Building Services Engineering, Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/Heikkila_et_al_2007 Other processes in the CPM Database also included in the above publication: - Bore-hole based air-conditioning system. ESA-DBP - Air-conditioning system. ESA-DBP - Air-and-water air conditioning system. ESA-DBP - All-air air handling unit with a cooling coil and vapour compression chiller with a refrigerant. ESA-DBP - All-air desiccant cooling air handling unit. ESA-DBP - Operation on vapour compression cooling system - a technology in air conditioning. ESA-DBP

System Boundaries

Nature Boundary	The inventory analysis included parameters describing resource use and emissions to air from the energy production.
Time Boundary	1995-2000
Geographical Boundary	Sweden
Other Boundaries	Main assumptions made for this study are: constant airflow, total airflow 5m3/s, supply air temperature - 17°C, exhaust air temperature - 24°C, operating time - 8760 [hours/year], SFP 2.4 [kW/(m3/s)]. Excerpt from the report, see 'Publication': ''The task of the system is ''to cool or heat a ventilating airflow of 5m3/s (100% outdoor air) to a constant supply air temperature of 17°C. The exhaust air temperature is 24°C and the exhaust air humidity ratio is 0.007 kg/kg higher than the supply air humidity ratio due to internal heat loads. Both air handling units are designed for a maximum specific fan power (SFP) of 2.4 kW/(m3/s), and the operational time is 24 hours per day during a whole year. The year 1990 is chosen out of hourly measured weather data for Stokholm, Sweden 1990. The year 1990 is chosen out of hourly measured weather data for period 1983-1992 because the number of hours with ambient air temperatures above 17°C this year is closest to the 10-year mean value. (...) The component performances are:

	- The supply and exhaust evaporative coolers' saturation efficiency is 80% - The sensible heat exchanger's temperature efficiency is 70% - The performance of the desiccant wheel is equivalent to a commercialy available component having a face velocity of 2.5 m/s and a rotor depth of 0.2 m.''

General Purpose	Excerpt from the report, see 'Publication': ''An objective of this work was that it should lead to an increased knowledge of how to work with environmental issues related to air-conditioning systems for office buildings and to a greater awareness of the environmental loads related to these systems. (...) The objectives of this thesis are to: - describe how the environmental performance of air-conditioning systems can be assessed and evaluated at the design stage. The focus is on the application of existing methods for environmental assessment of these systems. - identify and discuss the major sources of the environmental impacts and give some general recommendations as to how to design air-conditioning systems to improve their environmental performance. - outline possible key performance indicators (KPI) for the environmental performance of the most common types of air-conditioning systems.''
Detailed Purpose	Desiccant cooling is a one of the air conditioning technologies, therefore it was an object of the study.

Availability	Public

Technical System	
Name	Operation on train bearings - train type 'Regina'. ESA-DBP
Functional Unit	2 axleboxes with bearings on a distance of 100 000km
Functional Unit Explanation	Excerpt from the report, see 'Publication': ''The function of bearings in train wheels is to be the link between wheel axle and train car, and make the axle able to rotate. The functional unit (fu) is here defined as 2 axleboxes with bearings, mounted on a wheel axle in use on its matched Electric Multiple Unit (EMU) during 100 000 km of transport.''
Process Type	Gate to gate
Site	SKF Sverige AB 415 50 Göteborg
Sector	Land transport
Owner	SKF Sverige AB 415 50 Göteborg
Technical system description	The study was done for a a train 'Regina' which is manufactured by Adtranz, today Bombardier Transportation, since the year 2000. In this kind of train pre-lubricated, sealed Tapered Bearing Units, so-called TBUs are used. The Reginas are used on the Swedish West coast, in Mälardalen and in Bergslagen. Excerpt from the study, see 'Publication': ''The function of bearings in train wheels is to be the link between wheel axle and train car, and make the axle able to rotate. (...) The Regina TBU is named 1639605 C and contains the bearing BT2B 641157 CB. The axlebox has the number 432758. (...) When the trains are in operation the wheel axles and the inner rings of the bearings are rotating with a velocity proportional to the train speed. Because of friction between the bearing components, heat is generated in the axlebox, and at the same time the air outside helps cooling the axlebox. The consequence of the friction is a certain loss of power, and it is influenced by the construction of the bearing, lubrication, radial and axial load, rotational speed etc. The cooling factor is depending on e.g. materials, wind speed and ambient temperature. The calculations used in the study are performed in SKF Galaxy BeaTemp (version 3.1), a

	program that uses the equations published in the SKF General Catalogue to calculate the bearing temperature for which the generated heat is equal to the cooling. The bearing temperature, power loss and basic rating life are then given as outputs from the program. The equations used have been tried and verified by experimental results through several years of testing. The exact conditions for the train bearings could not be modelled in Galaxy, so some of the parameters had to be approximated. To get a realistic picture of the cooling for the actual situation, these parameters were matched to experimental results on bearing temperature from a field experiment with a train similar to X10. It is assumed that the radial load is equally distributed over the bearings on each train car, and that no axial load is present. The calculations are based on the duty mass.'' This process is included in the system described in: Jonasson K., Environmental Aspects of the Use-Phase for Bearings in Trains. Environmental Systems Analysis, Report 2003:3, ISSN 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2003--3.pdf Other processes in the CPM Database also included in the above publication: - Operation on train bearings - train type 'X1'. ESA-DBP - Operation on train bearings - train type 'X10'. ESA-DBP - Maintenance of train bearings - train type 'X1'. ESA-DBP - Maintenance of train bearings - train type 'X10'. ESA-DBP - Maintenance of train bearings - train type 'Regina'. ESA-DBP - Use phase of train bearings - train type 'X1'. ESA-DBP - Use phase of train bearings - train type 'X10'. System Boundaries

Nature Boundary	Excerpt from the report, see 'Publication': ''The one environmental aspect considered for train bearings in operation is electricity use. (...) Land, water and other types of resource use could not be assessed, due to lack of data.''
Time Boundary	Excerpt from the report, see 'Publication': ''The study is intended to illustrate the present situation, and the qualitative and quantitative information for the main processes are from the year 2001 until today. (NB: the report was written in 2003) Calculations indicated a basic rating life of more than 200 000 hours (...) , i.e. 30 years with a daily running time of 18 hours. It is assumed that the lifetime of the bearings is of the same size as for the trains, and thus can be neglected.''
Geographical Boundary	Excerpt from the report, see 'Publication': ''All the studied trains are in use in Sweden, where most of the maintenance is performed, too.''
Other Boundaries	Excerpt from the report, see 'Publication': ''The mass of passengers is neglected, but corresponds to roughly 10 percent of the duty mass if the train is half-filled. The ambient temperature used in the calculations was 10 degrees centigrade. (...) The total efficiency of the electrical supply system is 81.8 percent for X1 and X10. (...) Noise and vibration were not studied, and other environmental aspects of railway traffic operation were not regarded as being clearly related to the use of bearings. The environmental effects of industrial buildings, production of tools and machines, and the use of human labour are not included. The lifetime of bearings is generally given as basic rating life (L10h), which is 'the life that 90 percent of a sufficiently large group of apparently identical bearings can be expected to attain or exceed'.''
Allocations	Unknown
Systems Expansions	Not applicable

About Inventory

Publication	Jonasson K., Environmental Aspects of the Use-Phase for Bearings in Trains. Environmental Systems Analysis, Report 2003:3, ISSN 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2003--3.pdf

Intended User	LCA practitioner
General Purpose	Excerpt from the report, see 'Publication': ''The goal of this LCA is to investigate the environmental impact of the use-phase for bearings in trains. Three generations of trains, so-called Electrical Multiple Units (EMUs), will be studied, and comparison will be made between processes within the life cycle of the bearings, and between the bearings in the different generations of EMUs.''
Detailed Purpose	Operation of the bearings has a great importance in a use phase so it was necessary to investigate its impact.
Commissioner	SKF Sverige AB - 415 50 Göteborg .
Practitioner	Karl Jonasson - .
Reviewer	Björn Andersson, - Environmental Systems Analysis, Chalmers University of Technology
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	Excerpt from the report, see 'Publication': ''SKF provides both bearings and bearing housings for trains, called axleboxes, which are mounted in direct connection with the train's wheels to make the wheel axle able to rotate (...). The bearings used for this purpose are in this study referred to as 'train bearings', even though there are other fields of application for bearings in trains (e.g. in the traction system). What type of rolling bearings used for the wheel axle varies according to performance needs and train design, but the function is essentially the same.''

Technical System	
Name	Operation on train bearings - train type 'X10'. ESA-DBP
Functional Unit	2 axleboxes with bearings on a distance of 100 000km
Functional Unit Explanation	Excerpt from the report, see 'Publication': ''The function of bearings in train wheels is to be the link between wheel axle and train car, and make the axle able to rotate. The functional unit (fu) is here defined as 2 axleboxes with bearings, mounted on a wheel axle in use on its matched Electric Multiple Unit (EMU) during 100 000 km of transport.''
Process Type	Gate to gate
Site	SKF Sverige AB 415 50 Göteborg
Sector	Land transport
Owner	SKF Sverige AB 415 50 Göteborg
Technical system description	The study was done for a a train 'X10' which was manufactured by ASEA/ABB Traction during the years 1982-1993. In this kind of train an un-sealed Spherical Roller Bearings (SRBs) were used. More than 100 of X10s were produced and most of them are still in use especially in Stokholm, Gotheburg and Skåne area.

	Excerpt from the study, see 'Publication': ''During the 1990s some of the X10s were rebuilt with a different interior, and renamed to X11. These are also included under the designation X10 in this study, as the basic performance is the same. (...) The function of bearings in train wheels is to be the link between wheel axle and train car, and make the axle able to rotate. (...) The SRB used in X1-A, X1-B and X10 has the SKF product number 23226 CC/C3W33, and the axleboxes are called 723724, 723721 and 4000850 respectively. (...) When the trains are in operation the wheel axles and the inner rings of the bearings are rotating with a velocity proportional to the train speed. Because of friction between the bearing components, heat is generated in the axlebox, and at the same time the air outside helps cooling the axlebox. The consequence of the friction is a certain loss of power, and it is influenced by the construction of the bearing, lubrication, radial and axial load, rotational speed etc. The cooling factor is depending on e.g. materials, wind speed and ambient temperature. The calculations used in the study are performed in SKF Galaxy BeaTemp (version 3.1), a program that uses the equations published in the SKF General Catalogue to calculate the bearing temperature for which the generated heat is equal to the cooling. The bearing temperature, power loss and basic rating life are then given as outputs from the program. The equations used have been tried and verified by experimental results through several years of testing. The exact conditions for the train bearings could not be modelled in Galaxy, so some of the parameters had to be approximated. To get a realistic picture of the cooling for the actual situation, these parameters were matched to experimental results on bearing temperature from a field experiment with a train similar to X10. It is assumed that the radial load is equally distributed over the bearings on each train car, and that no axial load is present. The calculations are based on the duty mass.'' This process is included in the system described in: Jonasson K., Environmental Aspects of the Use-Phase for Bearings in Trains. Environmental Systems Analysis, Report 2003:3, ISSN 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. System Boundaries	
Nature Boundary	Excerpt from the report, see 'Publication': ''The one environmental aspect considered for train bearings in operation is electricity use. (...) Land, water and other types of resource use could not be assessed, due to lack of data.''
Time Boundary	Excerpt from the report, see 'Publication': ''The study is intended to illustrate the present situation, and the qualitative and quantitative information for the main processes are from the year 2001 until today. (NB: the report was written in 2003) Calculations indicated a basic rating life of more than 200 000 hours (...) , i.e. 30 years with a daily running time of 18 hours. It is assumed that the lifetime of the bearings is of the same size as for the trains, and thus can be neglected.''
Geographical Boundary	Excerpt from the report, see 'Publication': ''All the studied trains are in use in Sweden, where most of the maintenance is performed, too.''
Other Boundaries	Excerpt from the report, see 'Publication': ''The mass of passengers is neglected, but corresponds to roughly 10 percent of the duty mass if the train is half-filled. The ambient temperature used in the calculations was 10 degrees centigrade. (...) The total efficiency of the electrical supply system is 81.8 percent for X1 and X10. (...) Noise and vibration were not studied, and other environmental aspects of railway traffic operation were not regarded as being clearly related to the use of bearings. The environmental effects of industrial buildings, production of tools and machines, and the use of human labour are not included. (...) The lifetime of train bearings is not included in the study, as this primarily would affect the environmental impact of the production-phase in that a differing number of bearings would be needed to maintain the same function. It is thus included in the production-phase in the comparison with the operation, maintenance and transports processes. The lifetime of bearings is generally given as basic rating life (L10h), which is 'the life that 90 percent of a sufficiently large group of apparently identical bearings can be expected to attain or exceed'.''

Availability	Public

Technical System	
Name	Operation on vapour compression cooling system - a technology in air conditioning. ESA-DBP
Functional Unit	1 year of operation of vapour compression cooling system
Functional Unit Explanation	Energy use of vapour compression cooling system operated for 1 year. Operational time is 24 hours per day.
Process Type	Gate to gate
Site	Unknown
Sector	Goods and services for households
Owner	Unknown
Technical system description	Vapour compression cooling is a conventional technology in air air conditioning systems. It the paper it was compared to desiccant cooling system based on annual operating energy use during the use phase. Excerpt from the report, see 'Publication': ''One major difference of desiccant cooling compared to vapour compression cooling is that no ordinary refrigerant is needed. This eliminates the direct environmental impact due to unavoidable leakage during normal operation or a break down loss of the whole refrigerant charge. (...) Another difference between desiccant cooling and vapour compression cooling that affect the environmental impact is, that no electricity is needed for cooling the ventilating airflow. Generally, the electrical energy needed for operating the vapour compression system is less than the electrical energy needed for transporting the ventilating air to premises.'' The assumptions are the same as for desiccant cooling (see also: Operation on desiccant cooling system - a technology in air conditioning. ESA-DBP). The main are: constant airflow, total airflow 5 m3/s, supply air temperature = 17°C, exhaust air temperature = 24°C, operating time - 8760 [hours/year], SFP of 2.4 [kW/(m3/s)]. This process is included in the system described in: Heikkilä K. (2007). Environmental Assessment of Air-conditioning Systems. Design Considerations for Swedish Conditions. Report no. D 2007:2, Department of Building Services Engineering, Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/Heikkila_et_al_2007 Other processes in the CPM Database also included in the above publication: - Bore-hole based air-conditioning system. ESA-DBP - Air-conditioning system. ESA-DBP - Air-and-water air conditioning system. ESA-DBP - All-air air handling unit with a cooling coil and vapour compression chiller with a refrigerant. ESA-DBP - All-air desiccant cooling air handling unit. ESA-DBP - Operation on desiccant cooling system - a technology in air conditioning. ESA-DBP

System Boundaries	
Nature Boundary	The inventory analysis included parameters describing resource use and emissions to air and water from the energy production.
Time Boundary	1995-2000
Geographical Boundary	Sweden
Other Boundaries	Main assumptions made for this study are: constant airflow, total airflow 5m3/s, supply air temperature - 17°C, exhaust air temperature - 24°C, operating time - 8760 [hours/year], SFP 2.4 [kW/(m3/s)]. Excerpt from the report, see 'Publication': ''The vapour compression air-cooling process is modelled to be performed by a cooling coil with a constant surface temperature of 100'C. Graphically on a psychometric chart, in case of a wet (sensible or latent) cooling process, this means that the ambient air condition will change in the direction towards the air condition 10'C/100% RH. The evaporating temperature of the refrigerant is 15K lower than the coil surface temperature (-5°C). The condensing temperature is 15K higher than the actual ambient air temperature. Finally, the electricity use by the compressor for cooling the air is calculated hour by hour with a total Carnot efficiency of 0.5. In heating mode, a heat exchanger with the same temperature efficiency as in case of the desiccant cooling system is presumed. Consequently, the vapour compression system requires heat energy when ambient air temperature is below 0°C. The refrigerant is HFC-134a and the charge of the system is 23.5 kg. The annual leakage is assumed 2% of the charge.''

Intended User	LCA practitioner
General Purpose	Excerpt from the report, see 'Publication': ''An objective of this work was that it should lead to an increased knowledge of how to work with environmental issues related to air-conditioning systems for office buildings and to a greater awareness of the environmental loads related to these systems. (...) The objectives of this thesis are to: - describe how the environmental performance of air-conditioning systems can be assessed and evaluated at the design stage. The focus is on the application of existing methods for environmental assessment of these systems. - identify and discuss the major sources of the environmental impacts and give some general recommendations as to how to design air-conditioning systems to improve their environmental performance. - outline possible key performance indicators (KPI) for the environmental performance of the most common types of air-conditioning systems.''
Detailed Purpose	Vapour compression cooling is a one of the air conditioning technologies, therefore it was an object of the study.

Technical System	
Name	Ore-based steel production
Functional Unit	kg
Functional Unit Explanation	1 kg ore-based steel
Process Type	Cradle to gate

Site	Sweden
Sector	Materials and components
Owner	Sweden
Technical system description	The ore-based steel production includes Olivine and bentonite mining Iron-core mining, dressing, concentrating and pelletizing Lime production Coal mining Scrap refining Steel production (from pellets to slabs) Coking plant (with coal storage) Blast furnaces Steel plant (with lime kiln and continuous casting) Oxygen plant Rolling mill Olivine and bentonite mining Olivine is transported by truck or lorry about 50 km from Purnu (Iso Sormus) were it is mined, to LKAB Malmberget. Bentonite is imported from Greece and transported by boat 8500 km to Luleå and then by railway 260 km to Malmberget. Iron-core mining, dressing, concentrating and pelletizing Fines and pellets are produced, based on iron-ore. After mining, the granite is removed in the sorting plant by crushing, sifting and magnetic separation. The dressed iron-ore is then taken to the benefication plant, where about half of the quantity is wet-sifted and separated into sinterfines and sold as such. Remaining products from the dressing plant are used for pellets production in the pelletizing plant, in which the following activities occur: further concentration, adding of olivine, dewatering, rolling into pellets and finally a burning process. The pellets are transported by railway 260 km from LKAB Malmberget to Svartön in Luleå. Lime production Lime is taken from Gotland and transported by ship 1000 km to Luleå. Coal mining Coal is taken from USA (50%) and Australia (50%) directly to Luleå by large ships. The average distance is 500 km by train and 15 000 km by boat. Scrap refining Scrap is transported 40 km by lorry from earlier user to scrap refining plant. Swedish scrap is transported by train or by lorry, and the imported scrap is transported by boat. When assuming that 50% of the scrap comes from Sweden, 25% from Germany and remaining 25% from Poland, the weighed average transporting distance is 150 km by train, 50 km by lorry and 700 km by boat. Steel production (from pellets to slabs) The production process is divided into the following main steps: Coking plant (with coal storage) At the coking plant, coke is produced from coal for use in the blast furnaces. The coking process acts as a dry distillation without oxygen supply, where all volatile compounds are evaporated and a gas is obtained as a result. This gas is then further refined in several steps into coke gas. Sulphur, tar, benzene etc. are obtained as by-products and are sold. The coke is transported by assembly lines to the blast furnaces or to storing. The coke gas is used as a fuel in the coke battery and in the steamboilers. The excess gas is used in the blast furnaces or distributed to a power and heating plant. Bio sludge occurs as a low-grade product, as it is reused in the process. Blast furnaces In the blast furnaces, liquid raw iron (pig iron) is produced from pellets with reducing agents (coke and coal powder) slag formers (mainly lime) and some other additives. As raw materials are supplied from above in the furnaces, oxygen is added from beneath. The oxygen reacts with the coal and the gas is separated. The liquid iron sinks through the coal. The iron is tapped at intervals at the bottom of the furnace while the slag, floating at the surface, is tapped continuously from the surface. The iron is then transported in torpedos to the steel plant. Steel plant (with lime kiln and continuous casting) The raw, liquid iron is transported to the steel plant. In the desulphurizing process calcium carbide, magnesium and soda are added to the iron, reacting with the sulphur in the iron and producing slag that is removed. In the LD-converter the desulphurized raw iron is transformed into steel. The carbon content is decreased into less than 0.5% by blowing oxygen gas at the surface of the liquid iron, which makes the carbon oxidize and evaporate as gas. Steel scrap is added, both to cool and to serve as a raw material. Liquid steel and slag is tapped separately from each other. Argon is added from beneath to homogenize the steel. Small quantities of aluminum are added to remove any remaining oxygen. The liquid steel is then continuously cast into slabs. The slag is crushed and sieved into two fractions, one that is deposited and one that is reused in the blast furnaces. Excavation masses and industrial waste is landfilled or used as filling materials, both alternatives locally. Oxygen plant

	There is also a smaller cold-rolling mill that has not been taken into account in this study, since studied steel products do not pass this rolling mill. The steel slabs are transported from Luleå to Borlänge 863 km by train. Rolling mill All slabs are hot-rolled into coils. Around 50% of the coils are then further processed in the cold-rolling mill and 25% is then galvanized with a layer of zinc or an alloy of aluminum and zinc. Finally, some products get a coating of paint. Final products have a thickness of maximum 16 mm with a maximum breadth of 1600 mm. Main chemicals that are used are ammonia, oils, rolling liquids and chemicals for water treatment. Oil emissions to air as aerosols arise from the cold-rolling mill.

System Boundaries

Nature Boundary	The analysis comprises among other activities limestone quarrying, olivine-, bentonite-, coal and iron-ore mining, which implies that these raw materials are taken direct from the nature. Steel production Coking plant Parameters that have been measured but are below the detection level have been excluded; to air dioxines, to water oil, phenol, suspended solids, CN-tot, As, Cd, Mn and Zn. No waste of importance occurs. Steel plant Emissions to air and water Parameters that have been measured but are below the detection level have been excluded. All metal emissions to air accounted for are bound to particles, except Hg. Emissions to water arise from the blast furnaces, the continuous casting process and the rolling mill (emissions from the coking plant are accounted for). Rolling mill Emissions to air and water Hydrocarbon emissions to air have been omitted, as they arise from the coating process. Emissions to water are allocated to cold-rolled products.
Time Boundary	
Geographical Boundary	Sweden, except for bentonite which is imported from Greece, coal which is mined in USA and Australia and steel scrap which comes from Germany (25%) and from Poland (25%).
Other Boundaries	Steel production As coal is in this process used as a raw material, it is here accounted for as raw material, whereas the feedstock energy is accounted for at the coal extraction step. Blast furnaces Raw materials Manganese ore or manganese slag is used as an alloy material. Steel plant In lime is included all burnt lime and dolomite lime. Among the alloy materials, ferrous manganese, ferrosilicon manganese, aluminum and ferrosilicon are the ones mostly used. Additives mainly refers to calcium carbide. The most important chemicals are lubricating oils, anticorrosive agents and acids. Energy use Data for heating of buildings and internal transports for all connected activities is included. In industrial waste is also included construction and demolition waste, excluding excavation masses. Municipal waste is not considered. Hazardous waste mainly consists of residue oil and other waste with an oil content. Rolling mill Hazardous waste mainly consists of residue oil, oil-contaminated glow-scale sludge and sludge with a chromium and zinc content.
Allocations	Iron-core mining, dressing, concentrating and pelletizing: Raw material The raw ore used for the production process is equally allocated per weight on total production of fines and pellets, and so is olivine. Bentonite is allocated to production of pellets. Of the explosives (allocated to fines and pellets production by weight), 97% consist of Kimulux. About half the amount of chemicals used is hydraulic oil, and the rest is mainly defatteners, oils and lubricants. Accounted volumes of granite refer to dry weight. Chemicals are allocated to production of pellets. Explosives and chemicals are regarded in the calculations as non-elementary flows. Emissions to air and water Emissions to air are allocated to pellets production, since the main impact occurs at the pelletizing plant. CO2 emissions have been calculated based on use of fossil fuel. Most SO2 emissions (about 85%) arise from the sulphur content in the mineral, and combustion of fossil fuels is responsible for the rest. Emissions to water have been equally distributed per weight on production of both sinterfines and pellets. Emissions to water come from the sedimentation dams. Emissions to water are three times higher than measured average

	values as suggested in the environmental report, based on estimations of the annual overflow from the sedimentation dams. Waste Dry mineral waste (granite etc.) from mining and dressing is deposited within the production area or is used as a filling material for restauration of old open pit mines nearby. Mineral waste occurring from the concentration process follows as slurry with the flushing water from the process and is then stored in connection to a sedimentation dam. One third of the industrial waste is fines and pellets waste from internal research and development work. The industrial waste is transported by truck to a landfill about 2,5 km away. The hazardous waste consists of lubricants and residual oils. Granite waste is allocated to production of fines and pellets, and other waste is allocated to pellets production. Steel production Coking plant Like the coke, the products sulphur, tar, benzene, coke dust and coke gas all have an economic value. According to calculations made by Sunér M (Life Cycle Assessment of Aluminium, copper and steel. Report 1996:6, Technical Environmental Planning, Chalmers University of Technology, Göteborg, 1996) the value of produced coke stood in 1992 for 85,3% of the total economic value of the outflows of the coking plant. In table 6.5 allocation of the environmental load of the coking plant is based on this premise. Also, according to Sunér, 66% of the coke gas is used internally; 49% in the coke plant and 17% in the blast furnace. Blast furnace The total environmental impact is allocated to the iron. Steel plant Product The environmental load is distributed on total liquid steel production, including some raw steel which is sold before the casting process. Rolling mill Data refers to cold-rolled galvanized coils. For most parameters the environmental load is given aggregated for all process steps, and the load is then allocated to the production at the process step most responsible. The environmental loads that are specifically connected with the coating process are omitted in the calculations. Products Main products, to which the environmental impact is allocated, are hot-rolled coils, cold-rolled coils, galvanized and coated coils. Glow scale and ferrous oxide, scrap, zinc slag and aluminum slag are all defined as low-grade products, as they all have a market and are recycled or further used in other ways. No environmental impact is allocated to these low-grade products. Energy Use of electricity, fuel oil and liquefied petroleum gas (LP gas) is allocated between the process steps according to amount used in each process step. Use of petrol and diesel is equally distributed per weight on all products, independently of refining level. Emissions to air and water Emissions of NOx and particulates are based on measurements, and have been allocated equally per weight to all sold products. Waste Waste is allocated equally per weight on total production of coils.

Applicability	
About Data	Coal mining Half the amount of coal is imported from Australia and half from USA. The data used are average values for mineral coal used in Europe based on 50% open-pit mining and 50% underground mining. Steel production Blast furnaces Raw materials It is assumed in the calculations that all slag formers consist of lime. It is also assumed that coal used in the blast furnaces is the same as the coal used in the coking plant. Alloy materials are treated as non-elementary flows. Energy use Gases are taken from the coking plant and the blast furnaces. Use of blast furnace gas is not included in the calculations, as this energy originates from use of coke which is already accounted for as material use. Steel plant Products Material flows reused directly in the process are not accounted for. The low-grade products scrap and glow scale have an economic value, though minor compared to the main product, and they are therefore excluded in the calculations. No environmental load is allocated to these products. This is also the case for production of excavated masses (including the load from coking plant and blast furnaces). Raw materials Some chemicals that have originally been accounted for in volume have been recalculated

	into weight, assuming an average density of 1000 kg/m3. Alloy materials, additives and chemicals are regarded as non-elementary flows. Waste Since it is assumed that excavation masses have no further environmental consequences and may serve a useful purpose they are regarded as low-grade products, and no environmental load is allocated to them. Some categories of hazardous waste have been recalculated from volume to mass, assuming a density of 900 kg/m3. Rolling mill For the chosen process, about 70% of the slabs come from SSAB in Luleå, and remaining 30% is produced at SSAB in Oxelösund. It is assumed in the calculations that all slabs are produced in Luleå. Raw materials Alloy materials consist to about 80% of zinc, and the rest is aluminum. Although these products are refined in the Nordic countries, the ore is extracted in more distant countries. The environmental impact of extraction and refining of alloy materials are treated as non-elementary flows. Also acids and chemicals are regarded as non-elementary flows. Some liquid chemicals (like defatteners and anticorrosive agents) have been recalculated from volume into weight, and it is then assumed that one liter corresponds to one kg. Energy A minor quantity of energy is taken from the municipal district heating system, but since this amount is insignificant it has been neglected. Emissions to air and water CO2 emissions have been calculated based on consumption of fossil fuels (allocation based on fuel use in each process step). SO2 emissions are calculated based on sulphur content in fuel oil. Waste Some waste categories have been recalculated from volume to weight. A density of 850 kg/m3 has then been assumed for residue oil, oil sludge, fats and solvents and 1700 kg/m3 for glow-scale sludge. Internally recovered waste products have been omitted in the calculations (like used bate acids).

Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Passenger plane, MD-82
Functional Unit	1 tonkm, 300 km, 49 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for a flight distance of 300 km and a utilisation level of 49 % passenger occupation (6 450 kg).
Process Type	Unit operation
Site	Sweden
Sector	Air transport
Owner	Sweden
Technical system description	Operation of MD-82 aircraft carrying both passengers and cargo. The operation includes take-off, climb, cruise, descent and landing (including operations on the ground) *Technical data for the aircraft:* Maximum take-off weight: 67,8 tonnes. Maximum payload (i.e. maximum loading capacity with regard to weight): 17100 tonnes. Maximum loading capacity for the cargo: 3 tonnes Max cruising altitude 11,300 metres Cruising speed 815-825 km/h Length: 45.1 m Wing span: 32.9 m Range: 3,200 km Engine: P&W JT8D-217C/-219

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents aircraft in use in 1997
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The data is only valid for a flight distance of 300 km, and an average utilisation equivalent to 49 % (6 450 kg) passenger occupation. *Parameters not considered*

	-External conditions i.e. climate etc -Maintenance level of the aircraft. *Excluded subsystems* -Precombustion, i.e. production and distribution of the fuel -Maintenance of the aircraft -After-treatment of the aircraft -Handling of production rests
Allocations	The energy use and emissions only refer to the additional fuel consumption and emissions that occur as a result of the extra weight of the goods. The remaining energy use and emissions have been allocated to the passengers. This is a marginal argument based on the fact that only small amounts of goods are carried in passenger aircraft. The passenger occupation will thus have a large influence on the total energy use and emissions.
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Modeled data
Represents	See 'Function'
Method	The energy use and emissions only refer to the additional fuel consumption and emissions that occur as a result of the extra weight of the goods. The quantity value corresponds to a passenger occupation of 49% (6450 kg) and a flight distance of 300 km. The energy use and emissions was obtained by simulation calculations performed by FFA (The Aeronautical Research Institute of Sweden). The simulation calculations is performed in two steps. To obtain the fuel consumption, the flight path for each section is simulated, where both load and flight distance is accounted for. The position of the aircraft and the operation conditions of the engine are established for every second of the flight. This data is used in a new simulation where the exhaust emissions are calculated with regard to engine speed and flying altitude for every moment of the flight. The result from the simulation is then used to calculate the energy use and emissions per tonkm. The data include landing and take off, i.e. flight operations below 3000 feet (including operation of the ground), *Data used for the fuel:* -Thermal value: 43,2 MJ/kg -Sulphur content 500 ppm
Literature Reference	Larsson, Lars Gunnar, Calculations performed at FFA for NGM, 1997, Not published
Notes	The data is only valid for a flight distance of 300 km and was used as the maximum value for passenger planes in NGM The energy use and emissions vary substantially during the different phases of the flight. A flight may be considered to consist of 5 phases - take-off, climb, cruise, descent and landing (including operations on the ground). The take-off and climb are the most energy demanding phases and give rise to extensive emissions. For flights over 300 km, the energy use and emissions at take-off, climb, descent and landing may be considered to be constant, independent of the flight distance.

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 --- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology ---
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions

	associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Larson, Lars-Gunnar - FFA (Flygtekniska försöksanstalten), Box 11021 S-161 11 Bromma Sweden.
Reviewer	
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the plane, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. Goods transportation by air transport is done either in special freight planes or in regular passenger flights together with passengers. Air transport is primarily used for transportation of valuable or fragile goods and for speedy deliveries. Air transport is also more expensive than other modes of transportation. Consequently, very little goods are transported by aircraft. The major part of the goods is transported in regular passenger planes. The amount of goods that can be carried in passenger aircraft is however small. The average load of goods in a passenger aircraft is below 100 kg and is equivalent to an average passenger with average luggage. The passenger occupation will therefore have a large influence on the energy use and the emissions for goods carried in regular passenger aircraft. The MD-82 was chosen to represent Swedish air transport since it is one of the most common used aircraft in domestic regular traffic in Sweden. The aircraft represents an average regarding both technical standard and emissions. The aircraft has a long average lifetime. ***Utilisation level and distance*** For air transports, data on energy use and emissions per tonkm may only be given for a specific flight distance since the energy use and emissions vary substantially during the different phases of the flight. A flight may be considered to consist of 5 phases - take-off, climb, cruise, descent and landing (including operations on the ground). The take-off and climb are the most energy demanding phases and give rise to extensive emissions. For flights longer than 300 km, the energy use and emissions at take-off, climb, descent and landing may be considered to be constant, independent of the flight distance. Consequently, the longer the flight the more energy efficient transport. Aircraft are optimised for energy efficiency during the cruise phase. The average distance for Swedish domestic flights is between 300 and 600 km. Data for passenger planes was therefore only given for a short flight distance (300 km) and a low average utilisation level (49 %) and a long flight distance (600 km) and a high average utilisation level (81%). The reason for this was to give an indication of a maximum and a minimum value of the energy use and emissions for goods carried in passenger planes in Swedish domestic traffic. To calculate energy use and emissions for other flight distances, the following relations may be used, where x=total distance in km. These relations are valid for flights longer than 300 km and concern a MD-82 loaded with 9450 kg i.e. a utilisation level equivalent to a passenger occupation of 65%. -Kerosene: 2220 + 3,1*(x-300) [kg] -CO_2: 7015 + 9,8*(x-300) [kg] -CO: 9,6 + 0,0129*(x-300) [kg] -HC: 1,848 + 0,0049*(x-300) [kg] -NO_x: 29,85 + 0,031*(x-300) [kg] -SO_2: 2,22 + 0,003*(x-300) [kg]
About Data	The data was used as a maximum value for passenger planes in the work of NGM.The data is based on simulation calculations performed at FFA (The Aeronautical Research Institute of Sweden).

Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

A flight may be considered to consist of 5 phases - take-off, climb, cruise, descent and landing (including operations on the ground). The take-off and climb are the most energy demanding phases and give rise to extensive emissions. For flights over 300 km, the energy use and emissions at take-off, climb, descent and landing may be considered to be constant, independent of the flight distance.

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Larson, Lars-Gunnar - FFA (Flygtekniska försöksanstalten), Box 11021 S-161 11 Bromma Sweden.
Reviewer	
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the plane, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. Goods transportation by air transport is done either in special freight planes or in regular passenger flights together with passengers. Air transport is primarily used for transportation of valuable or fragile goods and for speedy deliveries. Air transport is also more expensive than other modes of transportation. Consequently, very little goods are transported by aircraft. The major part of the goods is transported in regular passenger planes. The amount of goods that can be carried in passenger aircraft is however small. The average load of goods in a passenger aircraft is below 100 kg and is equivalent to an average passenger with average luggage. The passenger occupation will therefore have a large influence on the energy use and the emissions for goods carried in regular passenger aircraft. The MD-82 was chosen to represent Swedish air transport since it is one of the most common used aircraft in domestic regular traffic in Sweden. The aircraft represents an average regarding both technical standard and emissions. The aircraft has a long average lifetime. ***Utilisation level and distance*** For air transports, data on energy use and emissions per tonkm may only be given for a specific flight distance since the energy use and emissions vary substantially during the different phases of the flight. A flight may be considered to consist of 5 phases - take-off, climb, cruise, descent and landing (including operations on the ground). The take-off and climb are the most energy demanding phases and give rise to extensive emissions. For flights longer than 300 km, the energy use and emissions at take-off, climb, descent and landing may be considered to be constant, independent of the flight distance. Consequently, the longer the flight the more energy efficient transport. Aircraft are optimised for energy efficiency during the cruise phase. The average distance for Swedish domestic flights is between 300 and 600 km. Data for passenger planes was therefore only given for a short flight distance (300 km) and a low average utilisation level (49 %) and a long flight distance (600 km) and a high average utilisation level (81%). The reason for this was to give an indication of a maximum and a minimum value of the energy use and emissions for goods carried in passenger planes in Swedish domestic traffic. To calculate energy use and emissions for other flight distances, the following relations may

	be used, where x=total distance in km. These relations are valid for flights longer than 300 km and concern a MD-82 loaded with 9450 kg i.e. a utilisation level equivalent to a passenger occupation of 65%. -Kerosene: 2220 + 3,1*(x-300) [kg] -CO2: 7015 + 9,8*(x-300) [kg] -CO: 9,6 + 0,0129*(x-300) [kg] -HC: 1,848 + 0,0049*(x-300) [kg] -NOx: 29,85 + 0,031*(x-300) [kg] -SO2: 2,22 + 0,003*(x-300) [kg]
About Data	The data was used as a minimum value in the work of NGM. The data is based on simulation calculations performed at FFA (The Aeronautical Research Institute of Sweden).
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Pea cultivation. ESA-DBP

Administrative	
Finished	Y
Date Completed	2005
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Pea cultivation. ESA-DBP
Functional Unit	1 kg of pea
Functional Unit Explanation	1 kg of pea on the yield with capacity 3400kg/ha
Process Type	Gate to gate
Site	Unknown
Sector	Crop and animal production, hunting etc.
Owner	Unknown
Technical system description	Excerpt from the report, see 'Publication': ''Peas require a relatively cool and humid climate, preferably in the temperature range of 7-30°C. They are cultivated in most parts of the world, being one of the most important legumes among soybean, groundnut, and beans. It is considered to be a suitable rotational crop, as it is self-providing with nitrogen and thus does not require additional fertilisers, except when nodulation is poor of fails completely. Crop rotation helps creating diversity in the agricultural system, and to use resources in an efficient way. (...) In this study we assume that the extra wheat generated replaces cultivation of winter wheat in a cereal crop rotation. Apart from increasing the yield, peas can also reduce the need for pesticides in the subsequent crop. (...) Harvested peas usually have a water content of about 20%, hence the crop has to be dried in order to reach the desired value for storage and processing of about 14-15%, this in order to maximise durability.

	Data on pea and wheat cultivation was taken from, based on a pea yield of 3 400 kg/ha.'' This process is included in the system described in: Abelmann A. (2005). Environmental Potential of Increased Human Consumption of Grain Legumes. An LCA of food products. Master thesis. ESA report 2005:10, ISSN: 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2005--10.pdf Other processes in the CPM Database also included in the above publication: - Sausage (Soy-Dog) production. ESA-DBP - Sausage (Pea-Dog) production. ESA-DBP - Sausage (Hot-Dog) production. ESA-DBP - Operation of 'Hot Dogs' producing facility. ESA-DBP - Production of beef. ESA-DBP - Production of pork. ESA-DBP - Rape seed cultivation. ESA-DBP - Wheat cultivation. ESA-DBP - Sugar beet cultivation. ESA-DBP - Soy bean processing. ESA-DBP - Soy bean cultivation. ESA-DBP

System Boundaries

Nature Boundary	Data include use of energy, as well as emissions to air and water.
Time Boundary	For the study data from the year 2005 were used.
Geographical Boundary	The study was done for Sweden.
Other Boundaries	Excerpt from the report, see 'Publication': ''Not included are any aspects regarding personnel. (...) For these reasons, pesticides, fungicides and herbicides are only taken into account quantitatively in the inventory section in this study (when data have been available), but are not analysed further in the results section. (...) some ingredients in the food processes have been judged to contribute very little to the overall process, and have therefore been excluded.
Allocations	No information about the allocation in the report.
Systems Expansions	Not applicable

Technical System	
Name	Peat fired plant for heat and power production

Functional Unit	1 kWh produced and delivered heat.
Functional Unit Explanation	The emissions and use of resources and raw materials are associated with the net production of 1 kWh heat.
Process Type	Gate to gate
Site	Sweden
Sector	Grid electricity and district heat
Owner	Sweden
Technical system description	BRIEF DESCRIPTION: This technical system describes the incineration process in a peat fired plant for heat and power production. The plant is located in Sweden and can be fired with oil, wood chips, pulverized peat and/or coal. Heat is produced and delivered to a district heating net. In this study the emissions from the incineration of peat is reported. Production of materials, chemicals, electricity and transport, used in association with the fuel chain and the operation and maintenance of the plant are not included. TECHNICAL DATA FOR THE STUDIED PLANT: The technical data presents the total production from the plant. The yearly production from different fuels could not be seperated. Average annual time of use (hours): 4300 (of which 3557 hours with peat) Total thermal and electric power output (MW): 330 Annual total fuel use (MWh): 1080789 Normal annual production of heat (MWh): 683388 Normal annual production of electricity (MWh): 314180 Degree of thermal efficiency (%): 92,3 PROCESS DESCRIPTION: The plant consists of one boiler unit. The thermal and electric power output, when peat or wood chips is incinerated, is 330 MW. The plant can also be fired with oil with a thermal and electric power output of 513 MW and coal with a thermal and electric power output of 335 MW. Only the incineration with peat is included in this study. The dust is removed from the flue gas in an electrostatic precipitator. The dust is then led to silos. The bottom ash is moistened and led to a container. INCLUDED OPERATIONS: The process study consists of the following operations: - The feeding of the pulverized peat into the combustion process. - The combustion process. - The removal of dust from the flue gas in the electrostatic precipitator. - The internal treatment of the residues from the combustion process. - The internal consumption of electricity. - The NOx control system. - Sulphur reduction system. NOx CONTROL: The boiler is equiped with SNCR system with urea as the reducing agent. - SNCR (Selective Noncatalytic Reduction) describes a method for reducing the NOx allready formed during the combustion process. In the process, an aqueous reduction agent mixed in water or steam is injected into the furnace during the combustion process. The reduction agent reduces the NOx and forms nitrogen and water. OTHER FLUE GAS CLEANING SYSTEMS: For the removal of dust from the flue gas an electrical precipitator is used. The plant is equipped with a dry flue gas cleaning system for the reduction of sulphur dioxide. Dolomite is added directly into the boiler, wherafter the dust and reaction products are separated in the electrostatic precipitator. After passage through a flue gas cooler, water and a mixture of separated ashes from the electrostatic precipitator and lime is added to the flue gas. Final flue gas cleaning take place in a dust filter bag. - In an electrostatic precipitator the dust particles are electrified and then separated from the flue gas stream by passing through an electric field with largest possible intensity. - In a dust filter bag the flue gas that contains dust is passed trough a tube made of felter cloth.

System Boundaries	
Nature Boundary	CRITERIAS USED FOR SELECTING FLOWS: Most data for reported in- and outflows are normally measured and reported once yearly in a public environmental report. The emission of HC is not measured.
Time Boundary	APPLICABLE TIME OF SYSTEM: This inventory was conducted using data mainly from 1996. The data consists of average data on a year basis. This data is assumed to be valid until new national or local regulations are enforced in Sweden.

Geographical Boundary	GEOGRAPHICAL EXTENSION (for large technical systems): This inventory has been conducted on a peat fired plant for heat production in Sweden, with swedish regulations, applicable during 1996. The collected data should only be used for swedish conditions.
Other Boundaries	NOTES OF EXCLUDED TECHNICAL SYSTEMS: The following operations has been excluded from the system: - The distribution of district heat from the plant to the consumers. - Building of the plant and the district heating net. - The cradle to gate of the internal electricity consumption. - The water consumption in the processes. - The breaking and refinement of the peat. - The transportation of the fuel to the plant. - The transportation of the residues from the combustion and cleaning processes to the landfill. - The processes at the landfill such as leaching, decomposition etc.
Allocations	PRINCIPLE APPLIED: In a combined power and heating plant two products of economic value are produced. For operation and maintenance of the plant the use of resources and the emissions are associated in relation to the net production of heat and power respectively. For the use of resources and the emissions that are specific for the electric power production ar e allocated to that production. Equivalent to this the use of resources and the emissions specific for the heat production are allocated to that. Note: When both heat and power are produced the allocation between the products are the same. That is the environmental load for 1 kWh produced heat are the same as for 1 kWh produced electrical power.
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1994-01-25
Data Type	
Represents	See 'Function'
Method	All data reported are related to the functional unit 1 kWh heat produced and delivered. The data is originally given as the avarage value for one our of an input (fuel, electricity etc.) to or an output (emission, product etc.) from the energy plant. The inputs and outputs are then related to the functional unit by dividing the avarage amounts eith the avarage amount of produced heat. For some flows specific information is given, see each flow.
Literature Reference	Data are in general recieved from ''Miljörapport 1996, Uppsala Energi AB'' accept for emission data to air which are recieved from the periodical inspection report for the plant in 1994 whith peat as fuel.
Notes	The parameters presented are chosen because they are available in the annual environmental report or in the periodical inspection report. Data can be missing if it is not reported in the reports The type of data reported is governed by the inspection authority. The reason for using the data from the periodical inspection report for peat combustion is that the emissions reported in the annual environmental report are not seperated for each fuel used over the year. The periodical enspection was performed using only peat as fuel, while in the annual environmental report all data reported were for the total of both peat and wood chips combusted during the year. All values are reported with 3 figures. The data are however seldom that accurate.

About Inventory

Publication	Data documented by: Maria Münter, Birgitta Olanders at SwedPower AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology

Intended User	Intended user of the data is t
General Purpose	The general purpose of the inventory was to obtain a lifecycle inventory of heat producing plants using different types of fuels. A further purpose was to obtain data from heat producing plant with different capacities.
Detailed Purpose	The specific purpose was to compare data from plants producing heat, with various fuels, combustion technologies and flue gas cleaning systems.
Commissioner	Bodlund, Birgit - Vattenfall AB.
Practitioner	- SwedPower AB, Maria Münter, Emanuel Nandorf, Pernilla Strömberg, Andrea Wallenius, Birgitta Olanders .
Reviewer	Pålsson, Ann-Christin - CPM Technical Environmental Planning Chalmers University of Technology 412 96 Göteborg
Applicability	CERTAIN CAUTIONS: This inventory has been conducted on a peat fired plant for heat and power production in Sweden, with swedish regulations, applicable during 1996. The collected data should only be used for swedish conditions. This data should only be used on plants producing heat in Sweden and for swedish conditions. When both heat and power are produced the allocation between the products are the same. That is the environmental load for 1 kWh produced heat are the same as for 1 kWh produced electrical power.
About Data	GENERAL DATA SOURCE DESCRIPTION: Data quality in the meaning good precision for the operation of the plant concerning for example the precision of emission measurements, calibration of instruments are good for plants larger than 10 MW and/or plants with a production larger than 25 GWh/year. These plants are included in the NOx control system . At these plants the instruments for NOx-controll and calculations are controlled every year at the periodical inspection. Most larger plants are also calibrating other instruments in there own intrerest or as a consequence of an internal control program.
Notes	Combined heat and power plants are used as base primarily during the winter half, when the use of heat and power are the largest.

SPINE LCI dataset: PET

Technical System	
Name	PET
Functional Unit	1 kg PET
Functional Unit Explanation	
Process Type	Cradle to gate
Site	
Sector	Materials and components
Owner	
Technical system description	The starting point for the commercial production of PET are ethylene for the production of ethylene glycol and para-xylene for the production of terephthalic acid. In practice there are two routes used in the production of PET precursors from p-xylene. Ethylene is produced by cracking either natural gas or the naphta fraction of crude oil. Before being used in the production of terephtalic acid, the different isomers of xylene are separated. Para-xylene is used in the production of PET because the ''straight'' chain structure is best suited to linear polymers.

	In practice, there are two routes used in the production of PET precursors from p-xylene. In the first, p-xylene is oxidised to terephthalic acid (TPA) which is then purified. This purified terephthalic acid is the reacted with etylene glycol to produce bishydroxyethyl terephthalate with water as a by-product. The alternative route oxidises p-xylene to terephthalic acid but then immediately reacts the acid with methanol to produce dimethyl terephthalate (DMT). When DMT is reacted with ethylene glycol, the result is bishydroxyethyl terephthalate as in the alternative route, but there is no a liberation of methanol rather than water. The methanol is recovered and re-used. The monomer from either route is then polymerised in the liquid phase to produce amorphous PET. This type of PET is suitable for the production of fibres and film. A second polymerisation in the solid state increases the molecular weight of the polymer and produces a partially crystalline resin that can be used to produce bottles via injection moulding and stretch blow moulding.

About Inventory

Publication	Eco-profiles of the Eurpean plastics industry Report 8 : Polyethylene Terephthalate (PET) APME technical report 07 1995 -- Data documented by: Sophie Louis, Volvo Technical Development Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	APME's eco-profiles serve two
General Purpose	There is an increasing demand concerning LCA data. Following this trend, APME members in Western Europe wanted to provide public ''Cradle to the gate data'' concerning their product's life-cycle.
Detailed Purpose	The aim here is to provide ''cradle to gate'' data for the manufacturing of PET
Commissioner	- APME, Avenue E. Van Nieuwenhuyse 4 Box 3 B-1160 Brussels.
Practitioner	Boustead, Ian Dr - .
Reviewer	
Applicability	The process examined here exists in Italy, Germany, the Netherlands and the United Kingdom. In the calculations, the fuel producing industries corresponding to the specific country have been used based on the data reported by the OECD.
About Data	The starting point for the commercial production of PET are ethylene for the production of ethylene glycol and para-xylene for the production of terephthalic acid. In practice there are two routes used in the production of PET precursors from p-xylene. Data have been collected from the producers of 160 000 tonnes of PET of which approximately 80 per cent is produced by the terephthalic acid route; the remainder is produced from dimethyl terephthalate. All data refer to a 12 month period during 1989 to 1991. Unlike the earlier reports in the series, the number of producers of PET and its immediate precursors is small and for these reasons the CEFIC rules on provision of statistics have been applied.

SPINE LCI dataset: Phosphatising of cast iron rings

Administrative

Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System

Name	Phosphatising of cast iron rings
Functional Unit	9.604 kg guide ring
Functional Unit Explanation	One guide ring of this specific model (RG-232/530 C/243475) weighs 9,604 kg. This dataset decribes inflows and outflows from a phosphatising process related to this guide ring. The guide ring will be mounted into an SKF Spherical roller bearing 232/530.
Process Type	Gate to gate
Site	SKF Mekan ABBox 89 641 21 Katrineholm
Sector	Materials and components
Owner	SKF Mekan ABBox 89 641 21 Katrineholm
Technical system description	This activity describes a process step included in the whole system activity ''Production of guide rings used for spherical roller bearings''', also available in the SPINE@CPM database. The guide ring is manufactured at SKF Mekan AB in Katrineholm and the process consists of several steps. See the activity ''Production of guide rings used for spherical roller bearings'' for details. The guide ring will finally be mounted into the SKF Spherical Roller Bearing 232/530. The function of the guide ring is to assure that the rollers stay in the raceways of the bearing. The guide ring is made of cast iron, produced mainly from scrap. After smelting of the raw materal the smelt iron is casted in a sand form. The cast iron is then further processed into guide rings. This dataset describes the phosphatising of the cast iron rings after the casting process. ------------------------- Phosphatising of cast iron rings: When the ring has been turned into its final shape, it is phosphatised. This is done to protect the surface from corrosion by adding rust inhibitors. First the ring is defatted in a highly alkaline bath. Then it is washed and treated in a bath with phosphoric acid. Finally it is treated in an oil-bath with corrosion protective agents and dried. All mentioned process steps are included in this data set.

System Boundaries

Nature Boundary	Many of the chemicals used in the turning process are not followed from the cradle, since it was too time consuming and the impact was assumed to be very small since the total amount was very small and the substances according to product data sheets not were considered hazardous. These inflows are considered non-elementary and come from the technosphere. Emissions to air and water are not included in this dataset since no information was available.
Time Boundary	The data was collected during the autumn 2002 and no changes in the procedure are planned for the nearest future.
Geographical Boundary	The phosphatising process take place in the maintreatment (KV) at SKF Mekan AB in Katrineholm, Sweden.
Other Boundaries	The energy needed to keep the temperature in each bath is NOT included in this study, since no information was available.
Allocations	Allocations have been made according to weight.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	02-08-01 - 02-12-31
Data Type	Derived, mixed
Represents	See 'Function'

Method	Data has been gathered from interviews and supplied material from Marja Andersson, SKF Mekan AB, in Katrineholm. She is responsible for environmental questions and much of the data comes from the environmental report from year 2001. All product data sheets for the different chemicals used were supplied by Marja Andersson, but since it was too time consuming, these inflows are not traced back to the cradle, but is set as non/elementary inflows from the technosphere.
Literature Reference	Eco-profiles of the European plastics industry Report 8 (07-1995) : Polyethylene terephthalate (PET) Association of Plastics Manufacturers in Europe Brussels - tel : +32 2 672 82 59
Notes	The parameters presented are chosen because they are available in the annual environmental report or in the periodical inspection report. Data can be missing if it is not reported in the reports The type of data reported is governed by the inspection authority. The reason for using the data from the periodical inspection report for peat combustion is that the emissions reported in the annual environmental report are not seperated for each fuel used over the year. The periodical enspection was performed using only peat as fuel, while in the annual environmental report all data reported were for the total of both peat and wood chips combusted during the year. All values are reported with 3 figures. The data are however seldom that accurate.

About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Thechnology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The data is valid for phosphatised cast iron rings at the specific site at SKF Mekan AB in Katrineholm, Sweden.
About Data	Data is gathered from interviews with Marja Andersson, SKF Mekan AB, Katrineholm.
Notes	

SPINE LCI dataset: Pickled hot rolled steel sheet

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Pickled hot rolled steel sheet
Functional Unit	1 kg pickled hot rolled steel sheet
Functional Unit Explanation	Before the steel can be coated, different pre treatments has to be done. The steel from the steel mill is first hot rolled and then pickled. After the pickling process, the steel is cold reduced and then finally coated.
Process Type	Gate to gate
Site	SSAB Tunnplåt
Sector	
Owner	SSAB Tunnplåt
Technical system description	This activity describes a process step included in the system ''Production of plywood boxes'', also available in the SPINE@CPM database. Plywood boxes are used to pack the coated and non-coated roller bearings from SKF, Göteborg, during the transportation to customers. The plywood boxes are manufactured by Nefab Emballage AB in Alfta, Sweden. The plywood box consist of plywood, steel strips, steel nails and wooden splits. The steel for the steel strips and steel nails is hot rolled, pickled, cold reduced and finally coated at SSAB Tunnplåt`s line in Borlänge. This dataset describes the production of 1 kg pickled hot rolled steel sheet at SSAB Tunnplåt AB in Borlänge. The environmental profile refers to the mean values of emissions to which the pickling lines

	and recovery of hydrocloric acid give rise in the production of pickled hot rolled steel sheet. All data for the process is obtained from an earlier LCA study at Nefab Emballage AB: Hillvall Maria; Transportförpackningars bidrag till reduktion av miljöbelastningen; Master Thesis at the Technical University of Luleå; 2000. The data refers to an existing EPD from SSAB Tunnplåt AB: Environmental Product Declaration from SSAB; SE 381; July 1999

System Boundaries

Nature Boundary	Emissions to air and water are included. The steel scrap from the process is reused as raw material and is thus not considered as waste, but as a co-product ending in the technosphere. The hydrochloric acid used in the process is recovered. For more detailed information see the EPD SE 381 from SSAB Tunnplåt AB.
Time Boundary	This environmental profile refers to the mean values of emissions to which the pickling lines and recovery of hydrochloric acid give rise in the production of pickled hot rolled steel sheet at SSAB Tunnplåt AB in Borlänge during the years 1998-1999. Changes in the process since then are not known.
Geographical Boundary	The hot rolling of steel sheet takes place at SSAB Tunnplåt´s line in Borlänge, Sweden.
Other Boundaries	The production of electricity is NOT included in the dataset, but must be followed from the cradle in order to obtain the total environmental impact. This must also be done with the production of LPG.
Allocations	Allocations have been made according to weight.
Systems Expansions	Not applicable

About Inventory

Publication	Blanco-Rosete S. R., 2002, LCA data structure and time series related to construction and maintenance in Sweden. Environmental Systems Analysis report 2002:14, Chalmers University of Technology, Gothenburg, Sweden

Intended User	LCA practitioners.
General Purpose	This process data set is recalculated to fit in the Master Thesis given in 'Publication'. Excerpt from the report (see 'Publication'): ''Construction, building maintenance and housing management contribute to a large extent to the environmental impact. When housing owners and managers perform their activities they should be aware of the environmental effects they cause. The environmental impact of existing houses could be addressed and diminished within the possibilities of a clever management.''
Detailed Purpose	Excerpt from the report (see 'Publication'): ''This master thesis descibes and defines a building system model for a multi-family house in Gothenburg over a 30 year period from 1970 to 2002 . The model was used to collect environmental impact information regarding materials or products used in the construction and maintenance of a building . The environmental impact ofa a multi-family house was evaluated through a Life Cycle Assessment (LCA). Finally to account the long sevice lifetime of a multi-family house two case studies were carried out to test if the use of Time series can illustrate the environmental impact of maintenance activities caused by decisionmaking in housing management.''
Commissioner	Not applicable - .
Practitioner	Sergio R. Blanco-Rosete - .

SPINE LCI dataset: Planting softwood plants

Administrative	
Finished	Y
Date Completed	1994-02-24
Copyright	None
Availability	Public

Technical System	
Name	Planting softwood plants
Functional Unit	Hectare
Functional Unit Explanation	Hectare planted forest land
Process Type	Gate to gate
Site	Sweden
Sector	Forestry
Owner	Sweden

Technical system description	Planting tree seedlings includes transport of tree plant to the forest and plantation. The transport is done by a truck transporting the plants from the plant nursery to the forest (40000 plant per truckload) and by a tractor in the forest (30kW). The plantation is done manually using a plantation tube (planteringsrör).and demands labor to be transported to the forest (a car takes the shift to the forest: 0,10 l diesel/km).

System Boundaries

Nature Boundary	The silviculture belongs to the system Emissions caused by combustion of diesel is not included.
Time Boundary	A gradual exchange of old machinery into newer, will decrease fuel consumption.
Geographical Boundary	Sweden
Other Boundaries	N/A
Allocations	N/A
Systems Expansions	N/A

Flow Data

About Inventory	
Publication	None -- Data documented by: Göran Swan, Ola Svending, STORA Corporate Research Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	LCA practitioners
General Purpose	The purpose is to supply with LCA-data for forestry to be used in further studies of wood products.
Detailed Purpose	Update of earlier studies of forestry.
Commissioner	- Stora Corporate Research, Box 601 661 29 Säffle Sweden.
Practitioner	Swan, Göran - Stora Corporate Research, Box 601, S-661 29 Säffle, Sweden.
Reviewer	
Applicability	These data are valid for large scale nursery in forestry. It is important to check the type of fuel used. In this case, fossil fuel is assumed to be used. Other data is available from other forest companies, or from Skogforsk, or STFI. The silviculture process in Sweden has eight steps: 1. Plant nursing 2. Soil preparation 3. Planting 4. Clearing 5. Thinning 6. Fertilizing 7. Final felling 8. Forwarding This is the third step. Forestry is also depending on natural regeneration, where the steps plant nursing, soil preparation and planting would be excluded. Approximately 20% (1997) of the total forest area is regenerated naturally.
About Data	These data depend to a great extent to which LCA-data on diesel and gasoline use that are used. The transport distances are representing a swedish average and may be greater in the northern part of Sweden.

About Inventory

Publication	LCA of Builing Frame Structures Environmental Impact over the Life Cycle of Wooden and Concrete frame; Björklund, Tillman; Report 1997:2; TEP; CTH; Göteborg; Sweden --- Data documented by: Maria Erixon, project employed for the database project at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Thomas Björklund, Technical Environmental Planning, Chalmers University of Technology ---
Intended User	To make an LCA of building fra
General Purpose	Among others, to analyse and assess the environmental impact of structural wooden and concrete frames in buildings during the whole life-cycle, by using the method of LCA as a tool.
Detailed Purpose	To calculate the environmental load of plasterboard
Commissioner	- Finncement Finland .
Practitioner	Björklund Thomas, Tillman Anne-Marie - Technical Environmental Planning, CTH 412 96 Göteborg Sweden.
Reviewer	
Applicability	This set of data is calculated for the type of plasterboard that is called Gyproc GN13, but both Gyproc U and Protect F may be substituted with the environmental data of Gyproc GN13. Three types of plasterboards are used in the wooden frame: Gyproc U, Gyproc GN13 and Gyproc Protect F. The first board is a thinner (9 mm) variant of the normal board which is 13 mm. The last board is a special fire protection board with a higher content of fiberglass; the last board also has a thickness of 15 mm and two other materials are included. The basis weight for Gyproc GN13 is 9 kg/m2; 12,5 kg/m2 for the Protect F board and 7,2 kg/m2 Gyproc U board. The difference in raw materials used, for Gyproc GN13 and Protect F, is presented below. Gyproc GN13 contains (weight %): Gypsum (95.2), Cardboard (4.9), Starch (0.3), Foam medium (0.07), Dispersion medium (0.05), Glue (0.03), Glass-fiber (0.03), Vermiculite & Kaolin (-). Protect F contains (weight %): Gypsum (86), Cardboard (3), Starch (0.3), Foam medium (-), Dispersion medium (0.2), Glue (<0.1), Glass-fiber (0.3), Vermiculite & Kaolin (10). The principal difference between the GN-board and the Protect 7 F board is the amount of gypsum used and the occurrence of Vermiculite and Kaolin in the Protect F board. The environmental load of the latter substances may be approximated to the data for mining of some sort, gypsum for instance, hence environmental wise no great difference exists. Because of this, both Gyproc U and Protect F may be substituted with the environmental data of Gyproc GN13. The function of the technical system is not sufficently described. Contact Gyproc AB Box 505 201 25 Malmö Sweden Phone +46 -40 165600 to get the necessary details.

Technical System

Name	Plastic waste incineration
Functional Unit	1 kg of plastic wastes
Functional Unit Explanation	1 kg of plastic wastes incinerated in the fluidized bed with energy recovery.
Process Type	Gate to grave
Site	Germany
Sector	Waste treatment
Owner	Germany
Technical system description	This data set represents the incineration of plastics collected by the Duales System Deutschland AG. The system studied starts with the collection and sorting of used packaging. The recycling scenario assumes that packaging wastes are collected from the consumer via a collection truck and transported to the sorting plant over an average distance of 80 km. The power consumption required for sorting is 40 kWh per tonne input. The sorting residues are landfilled. Landfilling of sorting residues and hazardous wastes (filter dust from fluidised bed combustion process) is included in the system. The plastic wastes are then transported over a distance of 200 km from the sorting plant to use in fluidized bed combustion and reduced in size with a power consumption of 200 kWh per tonne. The resulting material is used as a fuel in a fluidized bed kiln with a flue gas precipitation. The mass percentage of plastic wastes is as follows: Films: 9,0% Bottles: 7,5% Mixed plastics: 58,4% Sorting residue: 25,1% For the calculation of the mass balance of the combustion process, all input components of the furnace are split into their chemical composition. The calorific values are calculated from the elementary composition of plastic wastes. With the steam quality assumed (40 bar), an efficiency for electricity production of 17% is possible (steam reduction to 4 bar). Incineration of 1 kg of plastic waste thus yields 1,27 kWh electricity. The remaining steam (22,4 MJ) is assumed to be used completely. Literature reference: Recycling and Recovery of Plastics from Packagings in Domestic Waste. LCA-type analysis of different strategies. Michael Heyde, Markus Kremer. Institut Verfahrenstechnik und verpackung (IVV). Vol. 5. 1999 For more literature references see: ''About data''.

System Boundaries

Nature Boundary	The emissions to air and ground are included in the system. The input streams to the system are waste input, combustion air, auxiliary materials and energy for flue gas cleaning. Output streams leaving the system as solid materials are bed ash and boiler ash from the furnace and the residues from flue gas cleaning. The emissions to the atmosphere contained in the clean gas come from the flue gas purification.
Time Boundary	The data collection was performed in the period from 1993 to 1994. The study was reviewed and published in 1999. The data on transportation (distance, fuel demand, transport emissions) were collected in 1993. The data on sorting were collected from plant operators in 1994. The data on heat from natural gas boiler and grid power are collected in 1992.
Geographical Boundary	The study uses a wealth of data that appear to represent existing conditions of site-specific operations of the technically available recycling technologies in German at the time of the study.
Other Boundaries	The auxiliary materials used for the flue gas precipitation in the waste incineration plant are NaOH, ammonia and activated coke. The energy required for supplying these materials (0,3 MJ) is included in the balance. The auxiliary materials for the flue gas precipitation account for less than 3 wt% of the input of the waste to the incineration plant.

	The non-burnable components introduced into the system along with the fuel are precipitated as filter dust in fluidized bed combustion. Due to the high contamination with heavy metals, the filter dust must go to landfill for hazardous waste. The landfill for hazardous waste is considered to be free of emissions. The transport to landfill for hazardous waste is included in the system. It is assumed that there is a transport distance of 100 km to the landfill for hazardous waste.
Allocations	Not applied.
Systems Expansions	The electricity produced in the waste incineration is fed into the national grid. Electricity produced from plastics waste incineration is considered as a substituting electricity, which otherwise had to be produced from the primary energy carrier mix for German public grid. For the steam produced the substitution of steam from a natural gas heating station is assumed. The selected plant represents the state of art and meets German legal requirements on air-pollution control. The substitution factor used is 1 to 1. The waste incineration plant covers its own steam and power requirements, so that these must be substracted from the quantity of steam and power produced.

About Inventory

Publication	Recycling and Recovery of Plastics from Packagings in Domestic Waste. LCA-type analysis of different strategies. Michael Heyde, Markus Kremer. Institut Verfahrenstechnik und verpackung (IVV). Vol. 5. 1999 -- Data inserted by: Anastassia Manuilova. Chalmers University of Technology and Akzo Nobel Surface Chemistry AB. Data reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-05-28
Intended User	LCA practitioners in industry,
General Purpose	To evaluate the existing and principally available recycling processes for plastic wastes, and determine the environmental impacts from the processes.
Detailed Purpose	The goal of the study is to inform public and governmental authorities about environmental implications of recycling and recovery processes, which are already used or principally available for the treatment of plastics waste. And to provide scientific information as a prerequisite for a comparison of these recycling and recovery processes. The data were used in the Master of Science thesis work ''Life Cycle Assessment of Industrial Packaging for Chemicals''. Anastassia Manuilova. Chalmers University of Technology and Akzo Nobel Surface Chemistry AB. 2003. The overall aim of the study was to evaluate the potential environmental effect of steel and plastic packaging used at Akzo Nobel site Stenungsund over the entire life cycle with emphasis on reuse and recycling.
Commissioner	- Akzo Nobel Surface Chemistry AB 444 85 Stenungsund Sweden.
Practitioner	Manuilova, Anastassia - Akzo Nobel Surface Chemistry Environmental Development S-444 85 Stenungsund Sweden.
Reviewer	
Applicability	The results are in line with similar European studies. While the technologies analyzed appear to be applicable in other parts of Europe, upon closer inspection, the data supporting the environmental profile presented and the regulatory context originate from many specific German situations. This is particularly true for the data on transport, electricity generation and the performance of incineration. As a result, the relative environmental profiles of the processes studied could vary significantly if set other European contexts. Therefore, while very useful, the result of the study can only be applied to the rest of Europe if the local site-specific conditions are taken into account.
About Data	The data records used are based on measurement made on MSWI Wurzburg plant (empirically measured data adapted to the standard input of the study via model calculations in agreement with plant operators). The data on which calculation is based were collected in the years 1993-1994. The plant (MSWI Wurzburg) on which measurements were made corresponds to the state of the art and to the legal requirements. [IVV, 1999], [APME1, 1994], [APME2, 1994] The data on heat from natural gas boiler and grid power are collected in 1992 and come from [GEMIS] and other sources. The data on sorting are based on interviews with plant operators and were collected in 1994. [Heyde, 1994] The data on transport emissions and landfill are extracted from literature. The references mentioned above: [IVV, 1999] - Recycling and Recovery of Plastics from Packagings in Domestic Waste. LCA-type analysis of different strategies. Michael Heyde, Markus Kremer. Notes	The data were used in the Master of Science thesis work ''Life Cycle Assessment of Industrial Packaging for Chemicals''. Anastassia Manuilova. Chalmers University of Technology and Akzo Nobel Surface Chemistry AB. 2003.

SPINE LCI dataset: Plywood production

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Plywood production
Functional Unit	1 kg plywood
Functional Unit Explanation	1 kg plywood, will be further processed into a plywood box at Nefab Emballage AB in Alfta, Sweden. The plywood boxes will be used for transportation of SKF spherical roller bearings.
Process Type	Gate to gate
Site	Not relevant
Sector	Materials and components
Owner	Not relevant
Technical system description	This activity describes a process step included in the system ''Production of plywood boxes'', also available in the SPINE@CPM database. Plywood boxes are used to pack the coated and non-coated roller bearings from SKF, Göteborg, during the transportation to customers. The plywood boxes are manufactured by Nefab Emballage AB in Alfta, Sweden. This dataset describes the production of plywood. Nefab Emballage AB uses plywood (birchwood) from Russia, but LCA data is not available from their Russian suppliers. Instead we use data for Swedish plywood (pinewood). Source: EPD (9709077, Trätek Sweden, 1997) of wooden based board, 7 mm pinewood, produced by Edsbyn Träförädling AB. Inventory figures given in g/kg dry board, starting from extraction of resources and ending at the gate of the company. Moisture quotient, 9% = [Mass,wet-Mass,dry]/Mass,dry; => Mass change factor = 1,09; Using input flow (Mass,dry) for the calculations. Data is taken from an earlier LCA study made at Packforsk consulting AB: Weström Pär, Packforsk Consulting AB; Simplified life cycle assessment for the comparison of two packaging alternatives for medium-sized roller bearings; Report no. C00 528; April 2001.

System Boundaries	
Nature Boundary	The glue used for the plywwod production is approximated as crude oil. Data is taken from an earlier LCA study made at Packforsk Consulting AB: Weström Pär, Packforsk Consulting AB; Simplified life cycle assessment for the comparison of two packaging alternatives for medium-sized roller bearings; Report no. C00 528; April 2001. For further information we refer to this LCA.
Time Boundary	The EPD from where the data is taken by Packforsk Consulting AB is written 1997.
Geographical Boundary	The plywood production takes place in Edsbyn, Sweden.
Other Boundaries	The production of diesel, LPG and electricity is NOT included in this dataset and must be taken into account in order to calculate the total environmental impact.
Allocations	Allocations have been made according to weight.
Systems Expansions	Not Applicable

About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. Both types of bearings are packed in a plywood box. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.

Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998

	Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998

Technical system description	This set of data concerns the production of the polyurethane precursors (TDI, MDI, Polyols) and not the production of the polyurethane foam. The principal raw materials for polyurethane precursors are crude oil and natural gas. The diisocyantes having the greatest commercial importance originate from the aromatic content (benzene and toluene), while the polyols come almost exclusively from the aliphatic content. Diisocyanates are obtained by phosphogenation of daimines which are produced, via a number of intermediates steps, from aromatic hydrocarbons. The diisocyanate with the greatest technical importance are tolyene diisocyanante (TDI) and diphenylmethane diisocyanate (MDI).

	The polyols used in polyurethane production are predominantly hydroxy-polyesters. They are produced by alkoxylation. Depending on the degree of cross-linking required, the starting alcohols used for hydroxy-polyethers may be divalent glycols (ethylene, propylene and other glycols) or multivalent alcohols. The epoxides used are generally propylene oxide and ethylene oxide.

About Inventory	
Publication	Eco profiles ot the European plastics industry Report 9 : Polyurethane precursors (TDI, MDI, Polyols) APME technical report June 1996 -- Data documented by: Sophie Louis, Volvo Technical Development Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	APME's eco-profiles serve two
General Purpose	There is an increasing demand concerning LCA data. Following this trend, ISOPA [The European Isocyanate Producers Association] members in Western Europe wanted to provide public ''Cradle to the gate data'' concerning their product's life-cycle.
Detailed Purpose	The aim here is to provide ''cradle to gate'' data for the manufacturing of polyther/polyols
Commissioner	- ISOPA, Avenue E. van Nieuwenhuyse 4 Box 2 B 1160 Brussels.
Practitioner	Boustead, Ian Dr - .
Reviewer	
Applicability	Data on the production processes have been supplied by ARCO Chemical, BASF, BAYER, DOW, Enichem, ICI, Rhone Poulenc and Shell relating to plants operating in Belgium, France Germany, Italy, the Netherlands, Portugal, Spain and the United Kingdom.
About Data	The transport of the different precursors to the plant where is produced polyurethane foam is not included here in this set of data. Data have been obtained from plants producing some 590000 tonnes of polyether-polyols in 1990. It is important to recognise that the data do not refer only to the final conversions stages leading to polyether-polyols but to all operations starting with raw materials in the earth.

Technical System	
Name	Polyethylene
Functional Unit	1 kg of polyethylene
Functional Unit Explanation	In the calculations, additives such as anti oxydants, dyes and fillers were excluded, as was all the outer packaging for the final product. However, the calculations do include the conversion of the polymer resin into grannules.
Process Type	Cradle to gate

Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	Polyethylene is chemically one of the simplest polymers. Essentially, it is formed by opening the double bond in neighbouring ethylene monomer molecules and linking them together. The polyethylenes available commercially can be divided into three main groups : low density polyethylene, high density polyethyene and linear low density polyethylene. Low density polyethylene is produced in a high presure process and contains a high level of side branching with long side branches. High density polyethylene is produced in a low pressure process and contains fewer side branches. Linear low density polyethylene contains a large number of side branches, but these are very short so the polymer is able to pack well in the solid state.

Applicability	These data are available for polyethylene all grades. It means they are an average value of different types of polyethylene, which are following : LDPE, LLDPE and HDPE.
About Data	Data concerning inputs of energy and raw materials as well as air, water and solid waste emissions have been obtained from a total of 36 European ethylene polymeriastion plants producing 4,5 million tonnes of polyethylene of all grades. Of these, 10 plants produced 1,3 million tonnes of high density polymer, 22 plants produced 2,8 million tonnes of low density polymer and the remaining four plants were responsible for the production of 359 000 tonnes of linear low density polymer.

Technical System	
Name	Polymerization in LDPE production process. ESA-DBP
Functional Unit	1 kg of LDPE (low density polyethylene)
Functional Unit Explanation	
Process Type	Other
Site	Borealis, Sweden
Sector	Manufacturing
Owner	Borealis, Sweden
Technical system description	Polymerization discussed in this study is a one of the steps in crude oil based LDPE (low density polyethylene) production process. This process is gate-to-gate but the electricity and fuel are traced back to the cradle. In this step ethylene is processed into LDPE. Data are valid for Sweden but for electricity calculations average European data were used. Excerpt from the report, see 'Publication': ''Low density polyethylene (LDPE) is produced under high pressures (81-276MPa) and temperatures (130-330ºC) in either a tubular or stirring autoclave reactor. The products from this two reactor types differ mainly in their long chain branching composition due to differences in their backmixing. The result is shorter long-chain branching in stirring autoclave reactors, and longer in the tubular reactor. The mechanism leading to the formation of the branched polymer is chain growth polymerization. It includes four reaction steps: initiation, propagation, branching and termination. The initiation starts with the decomposition of an initiator material, usually peroxides. When exposed to heat or irradiation, the peroxides, decompose releasing a free radical, which attacks the ethylene and starts the growth of the radical chain. In the next step, the propagation, an olefin radical chain attacks the double bonds of the surrounding ethylene monomers causing an addition reaction to occur and results in a longer chain. In the process, the active center moves to the end of the new, longer chain and continues adding more monomers. The chain grows. However, the radical chain does not only react with double bonds in the monomers, but also with hydrogen from another polymer chain. The result is the termination of the first chain and a movement of the active center to the middle of the second chain, which now grows from there. This process is the called branching. The termination of the chain growth can be caused by different reactions. The two most important termination reactions are coupling and disproportionation. Coupling is the reaction of two polymer chains resulting in the formation of a long polymer molecule. Disproportionation is the transfer of a labile atom from one radical to another leading to two inert polymer chains. A third termination mechanism is chain transfer. It involves the transfer of the active center of a polymer chain to a monomer or to a solvent, added to the mix to terminate the chain growth. In dependence of the reactivity of the newly formed radical, it might initiate the formation of a new polymer chain. After the polymerization, the product stream passes through different separation steps to recover the not reacted ethylene gas for recycling and to remove waxes. The cleaned, molten polymer is then mixed with stabilizers and additives and finally made into pellets. In this last step, the polymer is forced through an extruder head to from the required shape and size of pellets. The pellets are usually cut under water and dried in a centrifugal drier.'' This process is included in the system described in: Liptow Ch., Tillman A.-M. (2009). Comparative life cycle assessment of polyethylene based on sugarcane and crude oil. Environmental Systems Analysis, Report 2009:14, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2009--14.pdf

	Other processes in the CPM Database also included in the above publication: - Ethylene production from cane based ethanol. ESA-DBP - Sugarcane cultivation. ESA-DBP - Refinery in crude oil based LDPE production process. ESA-DBP - Steam cracking in crude oil based LDPE production process. ESA-DBP

System Boundaries

Nature Boundary	Excerpt from the report, see 'Publication': ''Outputs accounted for in this study were by-products and emissions released to air. Water emissions were omitted, because of data unavailability for some parts of the sugarcane route.'' The data relate also to the fuel and electricity consumption which were traced back to the cradle.
Time Boundary	Data for steam cracking come from 2008 and they were acquired as the most up-to-date ones.
Geographical Boundary	Process data are valid for Sweden. For electricity calculations the average data from Europe were applied.
Other Boundaries	Excerpt from the report, see 'Publication': ''- total input treated as ethylene - production mix does not change with input composition - conversion rate does not change with input composition - external fuel treated like diesel to account environmental impact''
Allocations	No allocation needed.
Systems Expansions	Not applicable

Practitioner	Christin Liptow & Anne-Marie Tillman - Environmental Systems Analysis, Chalmers University of Technology.
Reviewer	Tillman, Anne-Marie - Environmental Systems Analysis, Chalmers University of Technology
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	Polymerization is a step in a production process of oil based LDPE which was the object of the study. The production process starts with crude oil extraction and is followed by refinery, steam cracking, polymerization, use phase (which was excluded from the study) and inceneration as the end of life. Oil based- was compared in the study to the sugarcane based- LDPE. NB: in the report two approaches were investigated: attributional and consequential. For consequential approach see the report.

Technical system description	Polypropylene is chemically similar to polyethylene. It is produced from propylene (propene) monomer. The polymerisation mechanism is similar to that for polyethylene ; the double bond on adjacent molecules is opened and the molecules combine to produce a polystructure. This structure is similar to polyethylene except that alternate carbon atoms are attached to a CH3 group rather than a hydrgen atom.

Technical System

Name	Portugal, electricity generation mix 1998
Functional Unit	Total electricity produced during 1998
Functional Unit Explanation	The electricity mix refer to the total amount of electricity generated by different power sources expressed in GWh during the year 1998.
Process Type	Unit operation
Site	Portugal
Sector	Energyware
Owner	Portugal
Technical system description	The generation of electricity with different power generating systems in Portugal during the year 1998. Portugal includes the Azores and Madeira.

System Boundaries

Nature Boundary	Not applicable, since the data only refer to the electricity generation mix. The environmental load for generation of electricity is not included.
Time Boundary	The data refer to 1998.
Geographical Boundary	Only electricity produced in Australia is considered. Import or export of electricity is not included.
Other Boundaries	-
Allocations	Not applicable
Systems Expansions	Not applicable

About Inventory	
Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998

SPINE LCI dataset: Potentiometer assembly

Administrative	
Finished	Y
Date Completed	2000-02-22
Copyright	Ericsson
Availability	Official

Technical System	
Name	Potentiometer assembly
Functional Unit	One gram potentiometer
Functional Unit Explanation	The motivation for choosing this functional unit is: · suitable unit to work with in an LCA of a private branch exchange (a complicated telecom product) · important component of the MD110 product system and many other electronic products. DESIGN These facts are based on Ericsson technical specification of the component. Ericsson product number: REL 320 0225/1 Ericsson description: Potentiometer General technical specification Single sliding potentiometer for hole mounting. The potentiometer is designed for both AC and DC applications. The lever is nonconductive. Weight: about 2.7 grams Terminal diameter: 0.7 - 1.3 mm Terminal length: 0.4 mm Height: 6.5 - 7.5 mm Length: 29.5 - 30.5 mm Width: 7.5 - 8.5 mm
Process Type	Gate to gate
Site	Not relevant
Sector	Manufacturing
Owner	Not relevant
Technical system description	This activity includes the final assembly of a potentiometer. The activity is based on information acquired from one manufacturer. The description of the process is assumed to be general for this type of manufacture. The following process steps are included; Typical steps are: 1. Printing 2. Curing 3. Punching 4 Terminal revetting 5. Molding 6. Assembling 7. Function test 8. Packaging 9. Final inspection Details given:

	1. Printing: Silver/carbon paste for conductive/resistive pattern is printed on a phenolic laminated substrate. 2. Curing: The paste is dried and cured. 3. Punching: Resistive element is punched out from the substrate. 4 Terminal revetting: metal terminals are riveted and attached to the resistive element. 5. Molding: plastic housing is formed around the resistive element. 6. Assembling: All parts are assembled.

System Boundaries

Nature Boundary	The emissons to air and water have nature as recipient. Each parameter mentioned by the component manufacturers have been studied. No parameter has deliberately been disregarded when environmental impact have been studied.
Time Boundary	1997 The answer from the manufacturer arrived in 1998 and they measured in 1997. The process technology used is most certainly the best available as the factory is located in Japan and the company is well established.
Geographical Boundary	The technical system for this model is limited to the factory where the production takes place. The manufacturer included in the average is located in Japan.
Other Boundaries	Delimitations to the system is the final step in the making of the potentiometer. The production of the subparts (e.g. galvanized sheet and phenolic laminated sheet) of the potentiometer is not included in this model. The transportation of them to the factory is not included. For interested parties who which wish to include the transport figures given from the manufacturer, can find the figures in the section Applicability.
Allocations	The manufacturers have not described how the allocation has been made. We did not decide or have any suggestions on how the manufacturer should allocate in their factory.
Systems Expansions	None.

Flow Data

General Activity QMetaData

Date Conceived	1999
Data Type	Derived, unspecified
Represents	See 'Function'
Method	The data that are presented are calculated based on information from one component manufacturer. The information from the manufacturer was acquired using a LCI data questionnaire. The average for each presented flow is calculated as follows: - First the amount of each flow per functional unit is calculated for each component manufacturer - Then the calculated amount for each component manufacturer is summed for each unique flow and divided by the number of included component manufacturers In the information supplied by the potentiometer manufacturer, they had indicated whether the data for each flow were measured, estimated or calculated. Below is a detailed account of the calculation procedure. Definition of variables: CMn: Component manufacturer number n. Myn: Materials, emission, waste, energy (y) given in component answer n. ACyn: Amount of material y in component, expressed in mg (or similar) by component manufacturer n Wn: Weight of one piece of component, expressed in mg (or similar) by component manufacturer n. Nyn: The flow y expressed per functional unit from manufacturer n. Step 1. For CM1 sum AC1+..+.ACn Step 2: The sum AC11+..+.ACyn = W1 Step 3: Divide all flows between M11...M1n by W1 --> N11...N1n Step 4: Repeat Step 1 to 3 for all component manufacturers and for each flow. Step 5: Sum N1n+..Nyn and divide by the number of terms for each unique flow.(material input, emission etc.)

About Inventory

Publication	Not available -- Data documented by: Anders Andrae, Ericsson Business Networks AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The intended use for this LCI
General Purpose	The general purpose with this LCI model was for application in a LCA project at Ericsson Business Networks. The main goal of the study is; to compare the potential environmental impacts associated with an old (BC 8) and a new model (BC 10) of a private branch exchange (PBX) system, namely the MD110 system, and an additional objective is to include comparisons between different stages of the life cycle (e.g. manufacturing, use and end of life) of the system. The system, PBX MD110, is designed, developed and delivered by Ericsson Enterprise Systems AB. Life-Cycle Assessment methodology (following the ISO14040 standards for LCAs) will be used to determine the environmental impacts. The main purpose of the study for Ericsson is; - to learn, test and evaluate the LCA-methodology as a tool for assessing environmental improvement options in the product design process, and to make up concrete product guidelines regarding design for environment (DfE) and - to evaluate environmental aspects in new design. The relative importance for different life cycle stages may also be an important input in the internal work with an Environmental Management System for Ericsson Enterprise Systems. Another purpose of the study is; to collect and qualify data from suppliers and literature in order to build up a database for this and future LCA activities and within the project, it is also intended to analyse the possibilities to use the study as a base for future work regarding a type III ecolabeling project within Ericsson. The intended audience of the report from the project is; Ericsson's personnel: project management, system management, design, marketing and sales organisation, and thus also (in an extracted version) the Ericsson customers.
Detailed Purpose	Map a potentiometer manufacturing/assembly process from an environmental standpoint in a structured procedure. The purpose of the project was to collect resource consumption data and emission data connected with the final assembly of potentiometers and resembling components in our telecom products. The usage for this set of data are life cycle assessments where potentiometers are part of the studied system. Note: This model is one of in total eighteen models compiled at Ericsson, describing 16 component groups in the PBX. The division into component groups is based on structural resemblance, electrical function and material contents of the different components. -- Below is a list of the component groups and corresponding models that have been compiled: 1. Cables - Model: Cable assembly 2. Capacitors and filters; hole mounted devices - Model: Capacitor for hole mounting assembly 3. Capacitors; surface mounted devices - Model: Capacitor for surface mounting assembly

	4. Connectors and holders - Model: Connector assembly 5. Diodes - Model: Diode wafer production and assembly 6. Display units and indicators - Model: Liquid crystal display assembly 7. Microcircuits, oscillators, quartz crystal units and delay lines (2 models) - Models: 1. Integrated circuit capsule assembly and 2. Si wafer production and Si wafer processing for integrated circuits (these models are interlinked) 8. Other - Model: ''Other'' electronic component assembly 9. Potentiometers - Model: Potentiometer assembly 10. Printed boards - Model: Printed board assembly 11. Relays - Model: Relay assembly 12. Resistor networks - Model: Resistor network assembly 13. Resistors, varistors and thermistors; hole mounted devices - Model: Resistor for hole mounting assembly 14. Resistors; surface mounted devices - Model: Resistor for surface mounting assembly 15. Transformers and inductors - Model: Inductor assembly 16. Transistors and opto couplers (2 models) - Models: 1. Transistor assembly and 2. Si wafer production and Si wafer processing for transistors (these models are interlinked)
Commissioner	- Ericsson .
Practitioner	Andrae, Anders - Ericsson Business Networks AB Augustendalsvägen 21 S-131 89 Stockholm Office: Nacka Strand .
Reviewer	Pålsson, Ann-Christin - CPM Chalmers University of Technology S-412 96 Göteborg Sweden
Applicability	This set of data can be applied to potentiometers in electronic equipment if you know how much the potentiometers weigh. -- Transports.-- Here follows a more detailed description of transports of materials and components to the manufacturer factory. These transports are not included in the model. The calculation for all modes of transport is done like this: First the total transportation work per functional unit is calculated for each included component manufacturer. Then the total transportation is summed and divided by the number of included component manufacturers. This gives the average value for transportation by each mode of transport. -- Truck transportation: -- Component manufacturer: Weight of component: 2.7171 g Galvanized sheet with weight 3.8 g is transported 500 km by road i.e. 3.8 g*500 km, Polyacetal 1.7 g*400 km, Polybutylene terphtalate 1.5 g*850 km, Carbon Steel 1.4 g*50 km and Phenolic laminated sheet 2.3 g*1200 km. The total transportation work is calculated as follows: The sum weight of the products materials and components given from material mass multiplied by distance divided by the weight of the component. This gives: 6685 gkm/2.7171 g = 2460.34 gkm/g -- Boat transportation: -- Carbon steel with weight 1.4 g is transported 1200 km by boat i.e. 1.4 g*1200 km. 1680 gkm/2.7171 g = 618.31 gkm/g
About Data	The data is based on information from one Japanese manufacturer. The information was gathered using a life cycle inventory questionnaire. The figures in the original answer from the manufacturers should all have a special tag telling if the value has been calculated, measured or estimated or a combination of two or three of them. Ericsson specifically told the manufacturers to do so. 18 % of the flows stated by CM have been just estimated. 41 % of the flows stated have first been estimated and the calculated and 41 % of the flows stated have been just calculated. The outline of the LCI data questionnaire that was used in the inventory follows below. No

	limitations or specifications were set for which substances they had to account. -- LCI data questionnaire -- Transport description: Material type, Used weight of Material (g)/functional unit, Transport by road of Material (km), Transport by boat of Material (km), Transport by rail of Material (km). We here only asked for flows exceeded 2% by weight of the material declaration of the component. Additional information was also asked for and here some manufacturers mentioned they had aeroplane transport instead of some of the other transport modes.´ Process description. Description of the entire production at the plant/site and a technical description of the plant production. Description of the production line of the studied product. Flow chart of process steps for production of the studied product. Technical description of the production line. A very short description of each unit operation. Data quality. For every figure you give, give an account on how you gatherd it. C = calculated, E = estimated, M = measured. General LCA-related information on the production system (Allocation procedures, system boundaries, etc.). Additional information. (e.g. planned changes in production rate) Material, components and natural resource input, etc. We told them to express data in amount per functional unit. Name of material, component or resource. Used amount(mg). Amount In Product(mg). Additional information Energy-ware input Energy -ware source. Quantity/functional unit. Unit. Energy-ware supplier, production site (address). Suppliers of transport (address). Additional information. Emissions. Emissions to air. Indicate whether emissions from energy use are included in the data. Name of emission to air. Emission to air/functional unit (mg). Additional information. Emissions to water. Indicate if data describes emissions going to external purification plant or directly to recipient. Name of emission to water. Emission to water/functional unit (mg). Additional information. Emissions to soil. Name of emission to soil. Emission to soil/functional unit (mg). Additional information. Waste. Name of waste. Waste/functional unit (mg). Recycled/functional unit (mg). Additional information.

Technical System	
Name	Preparation and anti-corrosive treatment of construction steel
Functional Unit	ton
Functional Unit Explanation	1 ton blasted and/or painted construction steel

Process Type	Gate to gate
Site	TIBNOR AB, GÖTEBORG Box 484 40127 Göteborg Sweden
Sector	Materials and components
Owner	TIBNOR AB, GÖTEBORG Box 484 40127 Göteborg Sweden
Technical system description	The company prosecute wholesales business, with a distribution stoorage. At the storage there is a painting plant, for construction steel, where preparation and anti-corrosive treatment is done. The treatment consist of blasting, priming and painting. Blasting and priming The painting plant consist of a prewarming zone, sling-cleaning machine, painting box and a drying tunnel. The goods are brought through the plant by a conveyor belt. In the sling-cleaning machine the goods are blasted with steel bullets. In this process dust containing metal is formed. The outgoing air is filtered by a locking filter of patron type. Two component epoxi/polyvinylbutyral shopprimer and thinner are used for painting. The solvents consist mainly of acetone, toluene and isopropyl alcohol. When using shopprimer and thinner organic solvents are emitted to the air. To limit the emission the painting plant is equiped with a thermal combustion plant. Air from the painting box and the drying tunnel is led to the combustion chamber, where the hydrocarbon is combusted at a temperature of 800 deg C. Cleansed heated air is used to heat the goods before the sling-cleaning and the painting. After the air has been heated it is led out through a heat exchanger above the roof. The smoke-stack ends 16 m above ground and 3 m above the roof.´Heat from the heat exchanger is used to raise the temperature in the drying tunnel. No process water arises and no abnormal surface water polution occur. Stored goods are not oil treated and oil is not used in the treatment of the material.

System Boundaries

Nature Boundary	The company is not obligated to state other emission- or waste substances than the Swedish Environmental Protection law requires.
Time Boundary	The company is obligated to write an Environmental report once every year. Though the legislated limits can be changed only if the activity is changed.
Geographical Boundary	Sweden

SPINE LCI dataset: Pre-stressing wire production

Administrative	
Finished	Y
Date Completed	1996-10-01
Copyright	
Availability	Public

Technical System	
Name	Pre-stressing wire production
Functional Unit	kg
Functional Unit Explanation	1 kg pre-stressing reinforcement wire
Process Type	Gate to gate
Site	Fundia Hjulsbro AB Box 344 581 03 Linköping Sweden
Sector	Materials and components
Owner	Fundia Hjulsbro AB Box 344 581 03 Linköping Sweden
Technical system description	Steel wire is the base for production of pre-stressing reinforcement wire. About 80% of the steel wire are taken from Fundia Wire Oy AB, a steelwork in Koverhar that is within the Fundia group. Some wire is also imported (about 20%), mainly from Germany and Belgium.

System Boundaries	
Nature Boundary	Emissions to air and water Emissions to air are not measured. Because of very small quantities, emissions to water (with the exception o suspended solids) are assumed as negligible and are omitted in the calculations.

Time Boundary	
Geographical Boundary	Sweden
Other Boundaries	
Allocations	As pre-stressing wire is the main product at Fundia Hjulsbro (a small quantity of other steel products is also produced), all environmental load is allocated to this product. However, raw material use is allocated equally per mass unit to all products. Scrap (36.3 g/kg) is regarded as a low-grade product, and thus no environmental impact is allocated to the scrap. All scrap is sent to Fundia Special Bar in Smedjebacken by railway for recycling.

Reviewer	
Applicability	To calculate the total environmental load for pre-stressing wire, including reinforcement steel production, you can use the data in this Database at:

	Name: Swedish reinforcement steel mix Category: Other Publication: LCA of Building Frame Structures Environmental Impact over the Life Cycle of Concrete and Steel frames; Björklund T., Jönsson Å., Tillman A-M.; Report 1996:8; Technical Environmental Planning; Chalmers University of Technology, Göteborg, Sweden The function of the technical system is not sufficently described. Contact the company to get the necessary details.
About Data	Raw materials Chemicals, in the calculations regarded as a non-elementary flow, to 77% consist of sulphuric acid but also of lime, lubricant oils, surface treatment liquids etc. Waste By industrial waste is referred to metal hydroxide sludge with a high lime content, combustible and non-combustible waste. Hazardous waste mainly consists of sulphuric acid, originally accounted for as volume (a density of 1000 g/l is assumed).
Notes	

SPINE LCI dataset: Pre-treatment of biowaste

Administrative	
Finished	Y
Date Completed	2002-08-14
Copyright	
Availability	Public

Technical System	
Name	Pre-treatment of biowaste
Functional Unit	1 tonne of biowaste
Functional Unit Explanation	1 tonne of biowaste containing non-recyclable paper (15 weight-%) and organic material (85 weight-%).
Process Type	Gate to gate
Site	Europe
Sector	Waste treatment
Owner	Europe
Technical system description	Pre-treatment of biowaste has two basic functions: The sorting of the organic material from other fractions in the incoming waste, and the preparation of this biowaste material for the subsequent biological processing - composting or biogasification. The biological treatment processes are not included in this activity. The amount of pre-treatment will depend on the nature of the incoming waste - the more narrowly defined the incoming material, the less separation will be required. The biowaste is sorted into two fractions, one for biogasification and one for composting. Pre-sorting residue is also an output of the system to account for material that is not biodegradable. Sorting techniques used are manual sorting and mechanical sorting. Preparation steps included are size reduction, homogenisation and moisture control. Although there is no standard pre-treatment process, an energy consumption of 25 kWh per input tonne is provided in the model as a default value. Energy consumption depends on which operation and which input waste stream that is used. (McDougall, IWM, 2001) This activity is a part of the aggregated system, Solid waste management. Pre-treatment distributes one fraction of biowaste to Composting and one to Biogasification. Reference: McDougall F. et al, Integrated Solid Waste Management: a Life Cycle Inventory, Procter & Gamble Technical Centres, Black Science, 2001.

System Boundaries

Nature Boundary	No emissions to air, water or ground are included due to lack of data.
Time Boundary	1992-2001
Geographical Boundary	The aim is that this Pre-treatment activity represents European conditions.
Other Boundaries	
Allocations	Not applicable
Systems Expansions	Not applicable

About Inventory

Publication	McDougall F. et al, Integrated Solid Waste Management - A Life Cycle Inventory, Procter & Gamble Technical Centres Limited, Blackwell Science, 2001 Data documented by: Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Documentation reviewed by: Ann-Christin Pålsson, Industrial Environmental Informatics, Chalmers University of Technology Published in SPINE@CPM: 14 August 2002
Intended User	The documentation of this syst
General Purpose	This activity was made to give an indication of pre-treatment of biowaste since data about waste management systems are insufficient and more data are required from the industry.
Detailed Purpose	The purpose of the documentation of this system has been to make data for Pre-treatment of biowaste, a part of Solid waste managment, available in this format for the industry. Data was put together by the person responsible for the documentation using the study Integrated Solid Waste Management F McDougall et al at Procter & Gamble Technical Centres, 2001 as a reference.

Commissioner	
Practitioner	
Reviewer	
Applicability	This activity can be used in the aggregated system of solid waste management only. The amount of waste to biogasification and composting depends on the availablity of biogasification plants. Biogasification is a more limited application but the number of facilities world-wide are increasing rapidly. In 2001 about 20-70% of biowaste produced can be treated in a biogasification plant, depending of the area. The type of pre-sorting installed affects the amount of secondary materials produced in a subsequent composting or biogasification plant depending on the composition of the input stream. A narrowly defined input, such as biowaste or vegetable/fruit and garden waste will contain a certain level of contamination; this material is not suitable for recovery.
About Data	Data in this activity is unspecified. Assumptions concerning pre-treatment of biowaste have been made by the person responsible for the documentation, e.g. 50% biowaste to composting. The descriptions of the activity is based on the study Integrated Solid Waste Management by F McDougall et al at Procter & Gamble Technical Centres, 2001. It is described how it was understood by the person who made the documentation.
Notes	For further information about solid waste managment see: Flemström K., Brief overview of solid waste management, IMI-internal report. The report may be downloaded from: http://www.imi.chalmers.se

SPINE LCI dataset: Primary aluminium production

Administrative	
Finished	Y
Date Completed	2002-05-07
Copyright	EAA
Availability	Public

Technical System	
Name	Primary aluminium production
Functional Unit	1000 kg aluminium ingot
Functional Unit Explanation	The aluminium ingots are delivered as slabs, billets etc.
Process Type	Cradle to gate
Site	Not specified. See Geographical boundaries for further information.
Sector	Materials and components
Owner	Not specified. See Geographical boundaries for further information.
Technical system description	This system represents the production of primary aluminium that are sold on the European market. Some import of aluminium is included. About 40% of the primary aluminium used in Europe is imported (19% from Russia and 20% from the western world outside Europe, during the years 1990-1999). The production includes the following process steps: 1. Bauxite mining 2. Transport of bauxite to alumina production plant (7453 km) 3. Production of alumina (aluminium oxide) 4. Transport of alumina to electrolysis (3998 km) 5. Electrolysis 6. Casting Some of the process steps are described in more detail below.

	3. Production of alumina (aluminium oxide): -- 3.1. Production of NaOH (caustic soda) 3.2. Transport of NaOH to alumina production plant 3.3. Limestone mining, lime calcination 3.4. Transport of lime to alumina production plant 3.5. Production of alumina at the alumina production plant.The main raw material for alumina is bauxite, which is extracted from bauxite mines and processed into aluminium oxide at alumina production plants. 5. Electrolysis: -- 5.1. Anode production, including anode butt recycling and transport to Electrolysis 5.1.1 Petrol coke and filling material production and transport to Anode production 5.1.2 Pitch production and transport to Anode production 5.2. Cathode production and transport to Electrolysis 5.3 AlF3 production and transport to Electrolysis 5.4. Production of liquid aluminium metal at the Electrolysis This system represents the European average situation, which uses about 15% Söderberg technology (anode consists of söderberg paste) and 85% Prebake technology (newer and cleaner technology with solid anodes) in the electrolysis. 6. Casting: -- Input material to this activity is liquid metal (from the electrolysis), alloying metals, and fluxing agents. A basic cast house have been worked out, i.e. typically yielding primary aluminium ingot for rolling, extrusion or remelting. No data for the production of alloying metals and fluxing agents is included in this data set. ENERGY CONSUMPTION/PRODUCTION The electrolysis, also referred to as the smelter, is by far the most energy consuming process in primary aluminium production. The total consumption in this system consists of the following elements: - rectifying loss - DC power usage - pollution control equipment - auxillary power (general plant use) - net electric transmission losses of 2% have been taken into account from power stations to primary smelters, as all primary smeltershave their energy delivered by high voltage lines from power stations located nearby, and operate their own transformer facilities. Use of energy and fossil fuel for electricity production and related air emissions is also included, except for nuclear and hydroelectricity which only includes the energy consumption in the distribution net. A model for electricity production has been applied to this system, in accordance with the fact that about 40% of the primary aluminium used in Europe is imported (19% from Russia and 20% from the western world outside Europe, during the years 1990-1999). See headline Method under the section General QMetaData to get more details on the electricity production model.

System Boundaries

Nature Boundary	--- BOUNDARIES VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- Cut-off criteria through out this inventory is basically relevance, as checked by the industry expert team monitoring the work and confirmed by reviewer I. Boustead. As a rough guideline ''less than 1% of total mass'' is applied for the inputs, i.e if the input is less than 1% of the total mass, then it is not included in the inventory table. The base for the choices of included inventory parameters is not further described in the EAA report.
Time Boundary	The data is collected between 1995 and 1998. Data for Bauxite mining is from 1991. Production of alumina (aluminium oxide): data for Limestone production from 1989-1994, data for Caustic soda production from 1999. Data for the electricity supply systems, the fuel production and use (energy carrier consumption, emissions) is from 1998.
Geographical Boundary	--- SPECIFIC BOUNDARIES FOR THIS DATA SET--- The aim of the study was to represent the European aluminium market, i.e. the environmental performance of aluminium products sold in Europe. The data is collected from European aluminum producers to provide LCA-practitioners with detailed and up-to-date information representing the aluminium industry activities in Europe. For the aluminium imported to Europe, the electricity production system in Russia and the west world have been regarded.

	--- BOUNDARIES VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- It is not always explicit in the report where the different included process steps take place. Data may be acquired from outside of Europe, e.g. regarding ancillary processes such as NaOH production, limestone mining, lime calcination, petrol coke production, pitch production, and AlF3 production. See litterature references (LitteratureRef) next to the flow table (FlowMetaData) for further information about the data sources for each process step.
Other Boundaries	See Nature boundaries for a specification of the cut-off criteria that has been applied. The production of alloying metals and fluxing agents is not included in this data set. The energy use presented as electricity (nuclear and hydro) in the inventory table includes the energy loss in the distribution net. The production of electricity by nuclear and hydro is however not included.
Allocations	Allocations are not explicitly specified in the Environmental Profile Report 2000.
Systems Expansions	System expansions are not explicitly specified in the Environmental Profile Report 2000.

Flow Data

General Activity QMetaData

Date Conceived	1989-1999
Data Type	Derived, unspecified
Represents	See LitteratureRef.
Method	The data is taken from the report ''Environmental Profile Report for the European Aluminium Industry'', European Aluminium Association, April 2000. INTERPRETATION OF FLOW TYPE AND ENVIRONMENT FOR INPUT FLOWS Several of the input flows is ambigously presented in the report. It is not clear whether they should be regarded as natural resources or refined resources. The interpretation in the documentation in this format is made based on the naming of the flows, e.g. steel bars is not considered to be a natural resource, and the description of included process steps. DATA SOURCES IN THE EAA-REPORT The sources of the various figures are aluminium company data in all cases in which the industry is directly involved in production. For other ancillary materials the data are in most cases supplied by the manufacturers of the products, but not necessarly all the plants supplying the European market. LCI data for primary aluminium production in this study derive from a survey for 1995, covering 92% of total European primary aluminium output. Another survey was carried out in 1998, covering 98% of the total European primary aluminium output, concentrating on parameters likely to have changed since 1995, i.e. about 30 major consumption or emission data items. The data is collected from the aluminium companies in all cases where this industry is directly involved in the production. For other ancillary materials the data are in most cases collected from the manufacturers of the products, but not necessarly all the plants supplying the European market. For those cases where EAA members' manufacturers' data were not available, published data have been used. See litterature references (LitteratureRef) next to the flow table (FlowMetaData) for information about the data sources from which the inventory parameters is derived. In addition to the figures provided by the EAA members, data has also been collected from elsewhere for the process steps in which the European aluminium industry is not involved, published data have been used, as referenced below: - Bauxite mining: BUWAL Environmental series no. 132 (1991), IPAI Bauxite Mine survey, other sources - Limestone production: I. Fecker, EMPA (1989), BUWAL Environmental series no. 132 (1991), Pechiney (1994), VAW (1994) - Caustic soda production: I.Boustead. Ecoprofiles of plastics and related intermediates, APME Brussels (1999) - Aluminium fuoride production: Norzinc/Alufluor/Pechiney (1994) - Petrol coke production: Pechiney (1994), APME report no.2 (1995), Statoil (Norway, 1995) - Pitch production: Hoogovens Staal, note 21 November 1997 METHOD FOR CALCULATION AND PRESENTATION OF ENERGY RESOURCES IN THE INVENTORY TABLE The procedure for calculating and presenting the input parameters (energy carriers) brown coal, hard coal, natural gas, and crude oil in the inventory table is presented below. It is based on the tables in the EAA report (see litterature reference). Each of the input parameters stated are described in the inventory table and related note field according to this procedure: A. Summary of the total energy resources for each energy carrier, respectively(from table 2.4 or 7.2) B. Statement of how many kg that are used for transport, process, and production of fuel and electricity (from table 2.4 or 7.2) C. Division of the energy resource input on the different process steps and statement on how much that are used for heat, electricity, feedstock and/or other (from table 7.2) D. Division of the transport data in to the various types of transports means in the different process steps (from table 7.2) METHOD FOR PRESENTATION OF SUBSTANCES, EXCEPT ENERGY RESOURCES The substances stated in the table is flows to the system as a whole, described in Function. In order to get information about the relevant connection of a substance to a process step, see Note for each specific flow. Further information regarding the contribution to a flow from a specific process step can be found in table 7.2 and 7.3 in the Environmental Profile Report, see Literature reference. However, due to the presentation form in the Environmental Profile Report, it is not possible to separate the data for all the process steps completely. SIGNIFICANT NUMBERS The numbers stated in this table is taken directly from the EAA report (see litterature reference), except for the energy resources, which is taken from the EAA report but recalculated as described above in ''Method for calculation and ...''. For the energy resources two significant numbers are always stated in the inventory table. This was chosen because of insufficient specification of the significant numbers stated in the report. For further details about the calculation and rounding, see Method for the specific flow. ELECTRICITY PRODUCTION MODEL FOR ELECTROLYSIS (PRIMARY SMELTER) A model for

	electricity production has been applied to this system, in accordance with the fact that about 40% of the primary aluminium used in Europe is imported (19% from Russia and 20% from the western world outside Europe, during the years 1990-1999). In the table below the share of aluminium produced in Europe, Russia and the West world (except Europe) is presented. Further, a specification of the electricity production model that has been used for the respective parts is presented. Smelters: European Russian West world (exc. Eur.) Total model Share of aluminium produced: 61% 19% 20% 100% Energy resources: brown coal 7,7% 16,1% - 5,1% hard coal 17,5% - 30,9% 20,0% natural gas 5,5% - 7,1% 4,6% crude oil 5,1% - 0,7% 3,1% nuclear electricity 23,6% 2,2% 0,4% 14,6% hydroelectricity 40,5% 81,7% 60,9% 52,6% Total 100% 100% 100% 100% The electricity supply systems have been taken from SAEFL Environmental Series 250 (1998) ''Buwal 250'' and EMPA report for EAA dated 27 April 1998, derived from Buwal 250 for national grid systems. Electricity used in Russian primary aluminium production is taken from a report by J. Schäfer (GDA, 1998) (a full reference to this report is not supplied in the Environmental Profile Report 2000). ELECTRICITY MODEL OUTSIDE ELECTROLYSIS AND CAST HOUSE OPERATIONS For all manufacturing operation other than electrolysis and cast house, the consumption of fossil fuels and emissions linked to electricity production was calculated according to the UCTPE 94 electrical energy model as described in BUWAL 250.
Literature Reference	- ''Environmental Profile Report for the European Aluminium Industry'', European Aluminium Association, April 2000. - Bauxite mining: BUWAL Environmental series no. 132 (1991), IPAI Bauxite Mine survey, other sources - Limestone production: I. Fecker, EMPA (1989), BUWAL Environmental series no. 132 (1991), Pechiney (1994), VAW (1994) - Caustic soda production: I.Boustead. Ecoprofiles of plastics and related intermediates, APME Brussels (1999) - Aluminium fuoride production: Norzinc/Alufluor/Pechiney (1994) - Petrol coke production: Pechiney (1994), APME report no.2 (1995), Statoil (Norway, 1995) - Pitch production: Hoogovens Staal, note 21 November 1997 - SAEFL Environmental Series 250 (1998) ''Buwal 250'' - EMPA report for EAA dated 27 April 1998, derived from Buwal 250 for national grid systems - Electricity used in Russian primary aluminium production is taken from a report by J. Schäfer (GDA, 1998)
Notes	The residues arising in alumina production often called ''red mud'', have been separated into major constituents, the main one being bauxite residue, which is a mixture of chemically inert mineral oxides.

Notes: The substance is used in the cast house.	Input	Refined resource	Alloying elements	10.8			kg	Technosphere	
Notes: The substance is used in the electrolysis.	Input	Refined resource	Aluminium hydroxide	12.5			kg	Technosphere	
Notes: The unit was not specified in table 7.2 from which the value is acquired from the report. However, all other flows are presented in kg. The substance is used in the cathode relining.	Input	Refined resource	Aluminium oxide	0.4			kg	Technosphere	
Notes: The substance is used in the cast house.	Input	Refined resource	Ar-gas	1.5			kg	Technosphere	
Notes: The unit was not specified in table 7.2 from which the value is acquired from the report. However, all other flows are presented in kg. The substance is used in the cathode relining.	Input	Refined resource	Blasting material	0.4			kg	Technosphere	
Notes: The substance is used in the electrolysis.	Input	Refined resource	Calcium fluoride	27.1			kg	Technosphere	
Notes: The substance is used in the cathode relining.	Input	Refined resource	Carbon blocks	7.5			kg	Technosphere	
Method: From table 7.2 Overall inventory LCI table: bauxite mining to electrolysis, including cast house and transport:input (see litterature reference for EAA report) the following calculations ha been made: Cast iron in electrolysis 3,5 kg + cast iron in cathode relining = 4,3 kg, which becomes 4 kg with one significant number. Notes: The substance is used in the electrolysis and cathode relining.	Input	Refined resource	Cast iron	4			kg	Technosphere	
Notes: The substance is used in the cast house.	Input	Refined resource	Cl2 gas	0.10			kg	Technosphere	
Notes: The substance is used in the electrolysis and cathode relining.	Input	Refined resource	Collar paste	6.5			kg	Technosphere	
Notes: The substance is used in the electrolysis.	Input	Refined resource	Cryolite	1.6			kg	Technosphere	
Method: The numerals are taken from the inventory table 2.4 and 7.4 in the Environmental Profile Report. The total summary for electricity is 3,6*10^2 kWh (243,2 + 9,6 + 3,2 + 99,0) kWh = 355 kWh --> 3,6*10^2 kWh (with two significant numbers) Notes: 255 kWh is nuclear electricity (243,2 kWh for electricity production and 9,6 kWh for transport of bauxite and 3,2 kWh for transport of alumina) and 99,0 kWh is hydroelectricity.	Input	Refined resource	Electricity	3.6E2			kWh	Technosphere	
Notes: The substance is used in the cast house.	Input	Refined resource	Fibre materials	0.11			kg	Technosphere	
Notes: The substance is used in the cast house.	Input	Refined resource	Fluxing salts	0.40			kg	Technosphere	

Notes: The substance is used in the cast house.	Input	Refined resource	Mineral/vegetal oil	0.08			kg	Technosphere	
Method: From table 7.2 Overall inventory LCI table: bauxite mining to electrolysis, including cast house and transport:input (see litterature reference for EAA report) the following calculations ha been made: 0,08 kg N2 in alumina production + 0,60 kg N2 in cast house = 0,68 kg, which becomes 0,7 kg with one significant number. Notes: N2 gas. The substance is used in the alumina production and Cast house.	Input	Refined resource	N2	0.7			kg	Technosphere	
Notes: The substance is used in the electrolysis.	Input	Refined resource	NaCO3	1.4			kg	Technosphere	
Notes: The substance is used in the alumina production.	Input	Refined resource	Organic components	1.1			kg	Technosphere	
Notes: The substance is used in the cast house.	Input	Refined resource	Packaging materials	1.80			kg	Technosphere	
Notes: The substance is used in the alumina production.	Input	Refined resource	Potassium chloride	3.0			kg	Technosphere	
Notes: The substance is used in the paste/anode plant, cathode relining, and cast house.	Input	Refined resource	Refractory materials	15.2			kg	Technosphere	
Notes: The substance is used in the cathode relining.	Input	Refined resource	Steel bars	5.1			kg	Technosphere	
Notes: The substance is used in the electrolysis.	Input	Refined resource	Sulphuric acid	31.4			kg	Technosphere	
Notes: Al203 residue for reuse.	Output	By-product	Al203 residue	0.40			kg	Technosphere	
Notes: Carbon material for fuel and recycling.	Output	By-product	Carbon material	21.4			kg	Technosphere	
	Output	By-product	Crushed bath sold	4.1			kg	Technosphere	
Notes: Dross and skimmings for recycling (metal yield 48%).	Output	By-product	Dross and skimmings	18.6			kg	Technosphere	
Notes: SPL carbon fuel/reuse. No specification of SPL is given in the report	Output	By-product	SPL carbon	6.6			kg	Technosphere	
Notes: SPL refractory bricks, reuse No specification of SPL is given in the report	Output	By-product	SPL refractory	1.7			kg	Technosphere	
	Output	By-product	Steel scrap	7.0			kg	Technosphere	
	Output	By-product	Swarf/turnings	0.84			kg	Technosphere	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	BOD	0.0024			kg	Water	
Method: The numerals are taken from the inventory table 2.4 and 7.4 in the Environmental Profile Report. (2,85 + 0,61) kg = 3,46 kg --> 3,5 kg (with two significant numbers) Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	CH4	20			kg	Air	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	Chlorides	56			kg	Water	
Method: The numerals are taken from the inventory table 2.4 and 7.4 in the Environmental Profile Report. (2,85 + 0,61) kg = 3,46 kg --> 3,5 kg (with two significant numbers) Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	CO	96			kg	Air	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	CO2	10 634			kg	Air	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	COD	0.23			kg	Water	
Notes: The substance is emitted from the electrolysis.	Output	Emission	Cyanide	0.00063			kg	Water	

Notes: The substance is emitted from the alumina production.	Output	Emission	Dissolved solids	1.73			kg	Water	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	Dust	27			kg	Air	
Notes: The substance is emitted from the electrolysis.	Output	Emission	F total	1.24			kg	Air	
Notes: The substance is emitted from the electrolysis.	Output	Emission	H+	0.018			kg	Water	
Notes: HC, other than PAH. The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	HC	0.016			kg	Water	
Notes: The substance HC includes all hydrocarbons except CH4 and PAH. The substance is emitted both from the alumina production and the electrolysis. 0,000 2 kg is air emission from the bauxite mining and alumina production process, 2,9 kg is from the transport of bauxite and alumina, 4,52 kg is from the fuel production and combustion, and 0,33 kg is from the production of electricity.	Output	Emission	HC	9.9			kg	Air	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	HCl	1.4			kg	Air	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	HF	0.75			kg	Air	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	Hg	0.00022			kg	Air	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	Hg	7E-6			kg	Water	
Notes: The substance is emitted from the alumina production.	Output	Emission	K+	0.089			kg	Water	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	N2O	0.0032			kg	Air	
Notes: The substance is emitted from the alumina production.	Output	Emission	Na+	9.3			kg	Water	
Notes: NH3, ammonia. The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	NH3	0.023			kg	Air	
Notes: Ammonium (NH4+). The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	NH4+	0.060			kg	Water	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	NO3-	0.24			kg	Water	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	NOx	27			kg	Air	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	Oil/grease	1.13			kg	Water	
Notes: Other metals emitted to air are Cd, Fe, Mn, Ni, Pb, Zn etc. The substance is not further specified in the report. The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	Other metals	0.5			kg	Air	
Notes: Other metals emitted to water as Al, As, Ba, Cd, Cr, Cu, Fe, Ni, Zn etc. No further specification is given in the report. The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	Other metals	8.6			kg	Water	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	PAH	0.014			kg	Water	
Notes: The substance PAH includes B(a)P. No further specifiction is found in the report. The substance is emitted both from the alumina production and	Output	Emission	PAH	3.3			g	Air	

the electrolysis.									
Notes: The substance PFC consists of approx. 90% CF4 and 10% C2F6. No explanation of the term PFC is given in the report. The substance is emitted from the electrolysis.	Output	Emission	PFC	0.28			kg	Air	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	Phenol	0.0061			kg	Water	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	Phosphate	0.17			kg	Water	
Date concieved: 1998 Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	SO2	71.6			kg	Air	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	Sulphates	34			kg	Water	
Notes: The substance is emitted both from the alumina production and the electrolysis.	Output	Emission	Suspended particles	4.4			kg	Water	
	Output	Product	Aluminium ingot	1000			kg	Technosphere	
Notes: The residue derives from the alumina production.	Output	Residue	Bauxite residue	1286			kg	Technosphere	
Notes: The residue derives from the electrolysis.	Output	Residue	Carbon waste	3.9			kg	Technosphere	
Notes: No specification of the substance is given in the report. The residue derives from the electrolysis.	Output	Residue	Dross fines	0.11			kg	Technosphere	
Notes: Dust from cyclones/ESP. The residue derives from the electrolysis.	Output	Residue	Dust	2.0			kg	Technosphere	
Notes: The residue derives from the electrolysis.	Output	Residue	Hazardous waste	0.32			kg	Technosphere	
Notes: Na as Na2O.	Output	Residue	Na2O	14.8			kg	Technosphere	
Notes: The residue derives from the alumina production.	Output	Residue	Na-oxalate	6.0			kg	Technosphere	
Notes: The residue derives from the electrolysis.	Output	Residue	Refrectory waste	7.0			kg	Technosphere	
Notes: The residue derives from the alumina production.	Output	Residue	Sand	98			kg	Technosphere	
Notes: The residue derives both from the alumina production and the electrolysis.	Output	Residue	Solid waste unspecified	64			kg	Technosphere	
	Output	Residue	Soot	1.2			kg	Technosphere	
Notes: No specification of the substance is given in the report The residue derives from the electrolysis.	Output	Residue	SPL carbon	7.7			kg	Technosphere	
Notes: No specification of the substance is given in the report The residue derives from the electrolysis.	Output	Residue	SPL refractory	15.2			kg	Technosphere	
Notes: The residue derives from the electrolysis.	Output	Residue	Tar waste	0.41			kg	Technosphere	

About Inventory

Publication	Environmental Profile Report for the European Aluminium Industry, European Aluminium Association, April 2000 -- Data documented by: Maria Erixon, IMI, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, IMI, Chalmers University of Technology Published in SPINE@CPM: 8 May 2002 --
Intended User	LCA-practitioners.
General Purpose	The European Aluminium Association (EAA) aims to contribute to further environmental improvements in aluminium products in a life cycle concept.

Detailed Purpose	The purpose with the Environmental Profile Report 2000 is to provide LCA-practitioners with detailed and up-to-date information representing the aluminium industry activities in Europe. The purposes with formatting the Environmental Profile Report 2000 for the European Aluminium Industry to the data documentation format SPINE, according to the data documentation criteria applied at Centre for environmental assessment of Product and Material systems (CPM) are: - CPM and European Aluminium Association (EAA) are anxious to provide life cycle assessment (LCA) practitioners with accurate and up to date environmental data for aluminium production. - EAA is interested in the SPINE formatting procedure and result, as the format is a base for (and therefor somewhat similar to) the new Technical Specification in ISO, ISO 14048, regarding LCA data documentation format. - EAA is interested in the CPM data quality control and documentation criteria.
Commissioner	- EAA (European Aluminium Association) 12 Av. de Broqueville B-1150 Brussels .

Reviewer	Dr. Ian Boustead, - 2 Black Cottages West Grinstead, Horsham GB-West Sussex RH13 7BD
Applicability	--- SPECIFIC INFORMATION FOR THIS DATA SET --- INFORMATION ABOUT THE SYSTEM This system represents the European average situation, which uses about 15% Söderberg technology (anode consists of söderberg paste) and 85% Prebake technology (newer and cleaner technology with solid anodes) in the electrolysis. The electrolysis, also referred to as the smelter, is by far the most energy consuming process in primary aluminium production. About 40% of the primary aluminium used in Europe is imported (19% from Russia and 20% from the western world outside Europe, during the years 1990-1999). An European model for electricity production has been applied to this system, according to this information. See headline Method under the section General QMetaData to get more information about the European electricity production model. CASTING At present cast houses in this industry vary significantly in age and size, and produce a wide variety of products and alloys. It has not been possible to produce one set of figures for every type of product and alloy, figures for a basic cast house have therefore been worked out, i.e. typically yielding primary aluminium ingot for rolling, extrusion or remelting. Data relative to specific further treatment of rolling and extrusion ingots, such as homogenisation, sawing, scalping etceteras are covered in later process steps, in the semi-finished product sections, also documented in SPINE format, see headline Semi-finished aluminium product fabrication above. ENERGY USE IN THE DIFFERENT INCLUDED PROCESS STEPS The energy directly consumed by the operations enclosed within the system bounderies, i.e. in the various production steps, are presented below. See the headline ''DATA SOURCES FOR FUELS/ENERGY PRODUCTION AND COMBUSTION'' in About Data for further information. ---3. Production of alumina (aluminium oxide) --- Fuel oil (kg) 487,5 Hard coal (kg) 16,4 Gas (kg) 65,1 Electricity UCTPE* (kWh) 602,0 ---5. Electrolysis--- Fuel oil (kg) 5,1 Gas (kg) 1,8 Electricity EAA-mix (kWh) 15574 Electricity UCTPE* (kWh) 2,6 ---5.1. Anode production, including anode butt recycling and transport to Electrolysis--- Fuel oil (kg) 25,7 Hard coal (kg) 2,0 Gas (kg) 65,3 Electricity UCTPE* (kWh) 84,3 ---5.2. Cathode production and transport to Electrolysis --- Fuel oil (kg) 0,1 Gas (kg) 0,6 Electricity UCTPE* (kWh) 4,0 ---6. Casting--- Fuel oil (kg) 10,5 Gas (kg) 13,9 Electricity EAA-mix (kWh) 16

* UCTPE 94 is an electrical energy model for energy supporting all processes in this system (including transports), except electrolysis and cast house. It is described in BUWAL 250, see litterature references.

--- GENERAL INFORMATION VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 ---

RECOMMENDATIONS BY EAA WHEN USING THE DATA

The data provided by the EAA members for their own process steps are the most up-to-date average data available for these processes, and it is recommended that they be used for LCA purposes. Older literature data should be disregarded, as it may no longer be representative due to technological improvements, progress in operating performance, changes with regard to raw materials or waste treatment, etc.

To complete the product system inventory, data
- on the production of consumer products, from semi-fabricated aluminium,
- on the performance of consumer products in the use phase, and
- on the recovery of scrap prior to remelting at the end of the product’s useful life
should be acquired.

EAA recommend that these data be used in LCA studies in accordance with methodologies within the framework of the international standards in the ISO 14040-series.

RELATED DATA SETS IN SPINE DATA FORMAT

The data presented in the Environmental Profile Report is reformatted in to the SPINE format and structured according to the SPINE concept in as many separate activities (sub-systems) as possible. The system scope for the study as a whole is primary aluminium production, semi-finished aluminium production, and recycling. The SPINE formatting resulted in 7 activities. These activities are all published in the SPINE@CPM database.

The production and recycling step are intended to be used together. For example, to obtain a cradle to gate-system for rolled aluminium sheet, the activity Primary aluminium production should be connected to the activity Production of rolled aluminium sheet. A recycling step (Aluminium recycling by refiners) could also be connected to such a system, depending on the scope.

-- List of activities formatted in the SPINE-format, published in SPINE@CPM --

Primary aluminium production
1. Primary aluminium production

Semi-finished aluminium product fabrication
2. Production of rolled aluminium sheet
3. Production of extruded aluminium profiles
4. Production of 0,02-0,2 mm single-rolled aluminium foil
5. Production of 0,005-0,02 mm double-rolled aluminium foil

Recycling
6. Re-melting of aluminium scrap
7. Aluminium recycling by refiners

Please note: The recycling process 6. Re-melting of aluminium scrap is included in the semi-finished aluminium product fabrication, i.e. activities 2-5. When designing a product system with the activities above where recycled aluminium is regarded, the activity Aluminium recycling by refiners should be used. The Re-melting of aluminium activity is only a specification if the user is specifically interested in this process step.

RECYCLING RATES FOR ALUMINIUM PRODUCTS AFTER USE

After use, aluminium products are a valuable re-usable resource. The European recycling rates for end products are currently around 95% for the automotive sector and 85% for the building sector.

IMPROVEMENTS IN THE ENVIRONMENTAL PERFORMANCE OF ALUMINIUM PRODUCTS AND PROCESSES OVER THE PAST FEW YEARS

Over the past few years EAA has achieved major improvements in the environmental performance of its production processes by means of the following:
- improvement on existing technology
- development and introduction of new technology and operations
- increased recycling of all materials in the production process.

Examples of major environmental improvements in aluminium products achieved over the past few years include:
- weight reduction by downgauging in the packaging sector
- energy savings through weight reduction and subsequent fuel reduction in the transport sector
- reduction of maintenance in the building sector

The previous Ecological Profile Report from EAA was published in 1996.

About Data	
	--- SPECIFIC INFORMATION FOR THIS DATA SET ---

DATA SOURCES

The sources of the various figures are aluminium company data in all cases in which the industry is directly involved in production. For other ancillary materials the data are in most cases supplied by the manufacturers of the products, but not necessarly all the plants supplying the European market.

In addition to the figures provided by the EAA members, data has also been collected from elsewhere for the process steps in which the European aluminium industry is not involved, i.e.:
- Bauxite mining
- Limestone production
- Caustic soda production
- Aluminium fluoride production
- Petrol coke production
- Pitch production

For those cases where EAA members' manufacturers' data were not available, published data have been used, see literature references.

DATA COLLECTION

The data is based on two surveys performed 1995 and 1998. LCI data for primary aluminium production derive from a survey for 1995, covering 92% of total European primary aluminium output. Another survey was carried out in 1998, covering 98% of the total European primary aluminium output, concentrating on parameters likely to have changed since 1995, i.e. about 30 major consumption or emission data items.

No data for the production of alloying metals and fluxing agents (added in the casthouse) is included in this data set.

AGGREGATION METHOD

Horizontal aggregation, i.e. averaging between primary plants for each fabrication step has been used in this report. This is chiefly because, apart from bauxite delivered to alumina plants, the supply of raw material to each individual plant varies with time (the bauxite supply to alumina production is relatively constant while the supply to other later process steps varies). The alternative would have been vertical aggregation, i.e. averaging the total production data for each smelter from bauxite, through the alumina plant and down to the smelter itself. However, the variation between the alumina plants, regarding the environmental profile, is in the range of +/- 15%, and as such would not have altered the overall result.

--- GENERAL INFORMATION VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 ---

PRECISION

According to EAA, the environmental data figures in the inventory table are usually accurate to a precision of 5%.

DATA SOURCES FOR FUELS/ENERGY PRODUCTION AND COMBUSTION

The electricity supply systems and fuel production and use (transport energy and emission data) have been taken from SAEFL Environmental Series 250 (1998) 'Buwal 250' and EMPA report for EAA dated 27 April 1998, derived from Buwal 250 for national grid systems.

All emissions connected with total fuel consumption (i.e. production and combustion of oil, gas or coal) have been taken from SAEFL Environmental Series 250 (1998) 'Buwal 250', table 16.9. Emissions from combustion only, i.e. excluding the contribution of the production of the fuel, have been considered where appropriate in order to make a direct comparision with the corresponding process emissions. Emission data for combustion came from a report prepared by EMPA for EEA (13 December 1997), showing the respective contributions of production and combustion of fuels in 'BUWAL 250, table 16.9'. Although emissions from fuel combustion were often covered in the industry survey reporting, data calculated from BUWAL 250 were always used, in view of the fact that the survey results were not sufficiently reliable due to inconsistent use of conversion factors.

REVIEW OUTSPOKE

Ian Boustead has reviewed and commented on the Environmental Profile Report for the European Aluminium Industry, April 2000, which is a revision of the first Ecological Profile Report from EAA that were published in 1996. Ian Bousteds' review comments on the Environmental Profile Report for the European Aluminium Industry, April 2000:

''...I have received the detailed calculations on which this present environmental report is based. All of the queries that I raised after working through these reports were answered satisfactory.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000

''Good-quality data were supplied by the EAA member companies, and the number of companies participating provides good coverage of the various processes, meaning that the

	results can be regarded as representative of the industryas a whole for the production of primary aluminium and subsequent conversion processes.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000 ''Because of the very fragmented nature of the recycling industry and wide variations in practices, it is recognised that the data presented for this sector of the industry can only be regarded as indicative. Nevertheless it is helpful to have such information from an authorative source.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000
Notes	REVIEWER Ian Boustead has reviewed and commented on the Environmental Profile Report for the European Aluminium Industry, which is a revision of the first Ecological Profile Report from EAA that were published in 1996. See AboutData for review comments.

SPINE LCI dataset: Printed board assembly

Administrative	
Finished	Y
Date Completed	2000-03-07
Copyright	Ericsson
Availability	Official

Technical System	
Name	Printed board assembly
Functional Unit	One m2 (square meter) printed board.
Functional Unit Explanation	The motivation for choosing this functional unit is: · suitable unit to work with in an LCA of a private branch exchange (a complicated telecom product) · important component of the MD110 product system and many other electronic products. DESIGN These facts are based on Ericsson technical specification of the component. Ericsson product number: TVM 113 5338 Ericsson description: Printed board General technical specification Dimension: 221.9 mm x 178.1 mm (i.e. app. 3.952 dm2) Number of layers: 4 Flammability rating: UL94V-0 Surface protection: Hot dip tinning Thickness without mask: 1.68 mm Weight: 137 g
Process Type	Gate to gate
Site	Not relevant
Sector	Manufacturing
Owner	Not relevant
Technical system description	This activity includes the final assembly of a printed board. The activity is an average based on information acquired from two manufacturers. The description of the process is supplied by manufacturer one, but is assumed to be general for this type of manufacture. The following process steps are included; Innerlayer manufacturing process: 1. Chemical pre-treatment 2. Punching of steering holes 3. Photoresistlamination

	4. Exponation 5. Developing of photoresist 6. Etching 7. Photoresiststripping 8. Automatic Optical Inspection, AOI 9. Brown oxidation 10. Heat treatment 11. Blading 12. Preassuring-after hardening 13. Baking 14. Steer hole taking 15. Clean sawing Hole metallized including multilyer board manufacturing process: 1. Affix-hole drilling 2. Component hole drilling 3. Direct metallization 4. Panel plating (of copper) 5. Chemical copper plating 6. Photoresistlamination 7. Electrified panel plating of copper 8. Electro tinning 9. Stripping 10. Etching 11. Tin stripping 12. Stone polishing 14. Automatic optical inspection 15. Stone polishing 16. Solder masking 17. Exponation 18. Pre-hardening 19. Developing 20. UV-hardening 21. Finishing hardening 22. Oxide protection 23. Electricity test 24. Contour treatment 25. Inspection 26. Packing According to CM1 these amounts of waste are recycled in the processes: Waste from photographical processes 13.3 g/m2 printed board area, Etchbaths 6913.2 g/m2, Oil (unspecified) 247.7 g/m2, NH3 3542.5 g/m2 and aluminium 0.4 g/m2. Detailed description in Swedish was given by manufacturer one (CM1). Manufacturer two (CM2) gave information about which process steps that occurred but no detailed information.

System Boundaries	
Nature Boundary	The emissions to air and water have nature as recipient. Each parameter mentioned by the component manufacturers has been studied. No parameter has deliberately been disregarded when environmental impacts have been studied. Both included component manufacturers answers have not specified the same parameters. In the cases where only one manufacturer has stated a parameter this has been used.
Time Boundary	1998 The answer from the manufacturer arrived in 1998 and they measured in 1998. The process technology used is most certainly the best available as the factories are located in Sweden and Italy and the companies are well established.
Geographical Boundary	The technical system for this model is limited to the factory where the production takes place. The manufacturers included in the average are located in Sweden and Italy.
Other Boundaries	Delimitations to the system is the final step in the making of the printed board. The production of the subparts (e.g. laminate, galvanic copper and soldermask) of the printed board is not included in this model The transportation of them to the factory is not included. For interested parties who which wish to include the transport figures given from the manufacturers, can find the figures in the section Applicability.
Allocations	The manufacturers have not described how the allocation has been made. Component manufacturer one (CM1) stated that the production of the product we asked for constituted 1% of total manufactured printed board area during 1998. We did not decide or have any suggestions on how the manufacturer should allocate in their factory.
Systems Expansions	None.

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, unspecified
Represents	See LitteratureRef.
Method	The data that are presented are calculated as a average based on information from two component manufacturers. The information from the manufacturers was acquired using a LCI data questionnaire. The average for each presented flow is calculated as follows: - First the amount of each flow per functional unit is calculated for each component manufacturer - Then the calculated amount for each component manufacturer is summed for each unique flow and divided by the number of included component manufacturers In the information supplied by the manufacturer, they had indicated whether the data for each flow were measured, estimated or calculated. Below is a detailed account of the calculation procedure. Definition of variables: CMn: Component manufacturer number n. Myn: Materials, emission, waste, energy (y) given in component answer n. ACyn: Amount of material y in component, expressed in mg (or similar) by component manufacturer n Wn: Weight of one piece of component, expressed in mg (or similar) by component manufacturer n. Nyn: The flow y expressed per functional unit from manufacturer n. Step 1. For CM1 sum AC1+..+.ACn Step 2: The sum AC11+..+.ACyn = W1 Step 3: Divide all flows between M11...M1n by W1 --> N11...N1n Step 4: Repeat Step 1 to 3 for all component manufacturers and for each flow. Step 5: Sum N1n+..Nyn and divide by the number of terms for each unique flow.(material input, emission etc.) An average calculation like above of up to two answers was made.

About Inventory

Publication	Not available -- Data documented by: Anders Andrae, Ericsson Business Networks AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The intended use for this LCI
General Purpose	The general purpose with this LCI model was for application in a LCA project at Ericsson Business Networks. The main goal of the study is; to compare the potential environmental impacts associated with an old (BC 8) and a new model (BC 10) of a private branch exchange (PBX) system, namely the MD110 system, and an additional objective is to include comparisons between different stages of the life cycle (e.g. manufacturing, use and end of life) of the system. The system, PBX MD110, is designed, developed and delivered by Ericsson Enterprise Systems AB. Life-Cycle Assessment methodology (following the ISO14040 standards for LCAs) will be used to determine the environmental impacts. The main purpose of the study for Ericsson is;

	- to learn, test and evaluate the LCA-methodology as a tool for assessing environmental improvement options in the product design process, and to make up concrete product guidelines regarding design for environment (DfE) and - to evaluate environmental aspects in new design. The relative importance for different life cycle stages may also be an important input in the internal work with an Environmental Management System for Ericsson Enterprise Systems. Another purpose of the study is; to collect and qualify data from suppliers and literature in order to build up a database for this and future LCA activities and within the project, it is also intended to analyse the possibilities to use the study as a base for future work regarding a type III ecolabeling project within Ericsson. The intended audience of the report from the project is; Ericsson's personnel: project management, system management, design, marketing and sales organisation, and thus also (in an extracted version) the Ericsson customers.
Detailed Purpose	Map a printed board manufacturing/assembly process from an environmental standpoint in a structured procedure. The purpose of the project was to collect resource consumption data and emission data connected with the final assembly of printed boards in our telecom products. The usage for this set of data are life cycle assessments where printed boards of different kinds are part of the studied system. Note: This model is one of in total eighteen models compiled at Ericsson, describing 16 component groups in the PBX. The division into component groups is based on structural resemblance, electrical function and material contents of the different components. --- Below is a list of the component groups and corresponding models that have been compiled: 1. Cables - Model: Cable assembly 2. Capacitors and filters; hole mounted devices - Model: Capacitor for hole mounting assembly 3. Capacitors; surface mounted devices - Model: Capacitor for surface mounting assembly 4. Connectors and holders - Model: Connector assembly 5. Diodes - Model: Diode wafer production and assembly 6. Display units and indicators - Model: Liquid crystal display assembly 7. Microcircuits, oscillators, quartz crystal units and delay lines (2 models) - Models: 1. Integrated circuit capsule assembly and 2. Si wafer production and Si wafer processing for integrated circuits (these models are interlinked) 8. Other - Model: ''Other'' electronic component assembly 9. Potentiometers - Model: Potentiometer assembly 10. Printed boards - Model: Printed board assembly 11. Relays - Model: Relay assembly 12. Resistor networks - Model: Resistor network assembly 13. Resistors, varistors and thermistors; hole mounted devices - Model: Resistor for hole mounting assembly 14. Resistors; surface mounted devices - Model: Resistor for surface mounting assembly 15. Transformers and inductors - Model: Inductor assembly 16. Transistors and opto couplers (2 models) - Models: 1. Transistor assembly and 2. Si wafer production and Si wafer processing for transistors (these models are interlinked)

Applicability	This set of data can be applied to printed boards in electronic equipment if you know the area of the printed boards. -- Transports.-- Here follows a more detailed description of transports of materials and components to the respective manufacturer factories. These transports are not included in the model.

The calculation for all modes of transport is done like this: First the total transportation work per functional unit is calculated for each included component manufacturer. Then the total transportation is summed and divided by the number of included component manufacturer. This gives the average transportation by each mode of transport.

-- Truck transportation: --

Component manufacturer one (CM1):

Weight of component: 157.91 g

Copper pellets with weight 20 g is transported 3 km by road i.e. 20 g*3 km, Tin 1.26 g*3 km, Solder 10.4 g*10 km, Photoresist 4.1 g* 1500 km and 4.1 g * 960 km, Paper 5.9 g*400 km, Slip foil 1 g*200 km, Laminate 86.2 g*400 km, Prepreg 37 g*400 km, Copper foil 14.3 g*400 km, Aluminium 0.16 g*30 km, Drill mat 72.5 g*200 km, HCl 240 g*400 km, H_2SO_4 50 g*400 km, H_2O_2 40 g*400 km, NaOH 100 g*400 km, Alcalic etchfluid 140 g*400 km, Probimer laquer 7,9 g*900 km, Aqua flux 10 g*10 km, Aqua oil 20 g*10 km, $FeCl_3$ 20 g*10 km, $Ca(OH)_2$ 40 g*120 km and Gammabutyrolactone 340 g*200 km.

The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives:

392868.58 gkm/157.91 g = 2487 gkm/g
392868.58 gkm/0.03952 m2 = 9.94e6 gkm/m2 = 9.94 ton*km/m2

Component manufacturer two (CM2):

Weight of component: 160.59 g

FR4 (laminate) with weight 50 g is transported 200 km by road i.e. 50 g*200 km, Base material copper 50 g*200 km, Galvanic copper 47 g*200 km, Sn/Pb 5.27 g*100 km and Soldermask 8.32 g*500 km.

The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives:

34087 gkm/160.59 g = 212.26 gkm/g
34087 gkm/0.03952 g = 862.52e3 gkm/m2

This gives the average total transportation work by truck for CM1 and CM2:

MASS, (CM1+CM2)/2= 1349.63 gkm/g
SURFACE, (CM1+CM2)/2= 5.4e6 gkm/m2

-- Boat transportation: --

Component manufacturer one (CM1):

Weight of component: 157.91 g

Photoresist with weight 4.1 g is transported 250 km by boat, i.e. 4.1 * 250 km, 4.1 g * 1250 km, Alcalic etchfluid 140 g*400 km and Probimer laquer 7,9 g*900 km.

The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives:

356.94e3 gkm/157.91 g = 2260.4 gkm/g
356.94e3 gkm/0.03952 m2 = 9e6 gkm/m2

About Data

The data is based on information from one Swedish manufacturer and one Italian. The information was gathered using a life cycle inventory questionnaire.

All flows are not average values and where there were only one manufacturer stating a certain flow, this one was chosen in the model.

Of the flows about little more than 84 % are not average values. The flows for Raw material input of FR4 laminate, Copper, Lacquer, Sn and Pb are average values.

In specific QMetaData for each flow, we have indicated specifically for each flow how many manufacturers have been included.

The figures in the original answer from the manufacturers should all have a special tag telling if the value has been calculated, measured or estimated or a combination of two or three of them. Ericsson specifically told the manufacturers to do so.

16 % of the flows stated by CM1 and CM2 have been just measured, 53 % of the flows have just been calculated, 13 % estimated and 18 % first measured and then calculated. CM1 have not stated any information about the flows.

In specific QmetaData we have indicated specifically for each flow how many manufacturers have been included for each flow.

The outline of the LCI data questionnaire that were used in the inventory follows below. No limitations or specifications were set for which substances they had to account

	-- LCI data questionnaire -- Transport description: Material type, Used weight of Material (g)/functional unit, Transport by road of Material (km), Transport by boat of Material (km), Transport by rail of Material (km). We here only asked for flows exceeded 2% by weight of the material declaration of the component. Additional information was also asked for and here some manufacturers mentioned they had aeroplane transport instead of some of the other transport modes.´ Process description. Description of the entire production at the plant/site and a technical description of the plant production. Description of the production line of the studied product. Flow chart of process steps for production of the studied product. Technical description of the production line. A very short description of each unit operation. Data quality. For every figure you give, give an account on how you gatherd it. C = calculated, E = estimated, M = measured. General LCA-related information on the production system (Allocation procedures, system boundaries, etc.). Additional information. (e.g. planned changes in production rate) Material, components and natural resource input, etc. We told them to express data in amount per functional unit. Name of material, component or resource. Technical system description	The company runs printing enterprise. The plant consists of three departments, paper printing, media printing and electrical/mechanical workshop. A detalied description of the different departments follows below: Paper printing There are four rulloffsetpresses, three heatsetpresses, paper storage and workshops in the department. Two of the rulloffsetpresses have the size of eight A4 pages. The other two have the size of sixteen A4 pages. The paper is continously fed into the rolloffpress from a roller. The paper passes throught a couple of printing mechanisms, each applying one colour. The print is then dryed in an oven, cooled, cut and folded into the final product. Contaminations from solvents in the air, led from the rulloffsetpresses, are removed in a catalytic oxidation plant (Haldor Topsöe, of Regenox type), with 97% cleaning efficiency. The cleansed air is emitted through a smoke-stack 14 meters above ground. The air from the oven contains solvents and is therefore led to a thermal combustion plant (MEG-Therm), with 90% cleaning efficiency. The cleansed air is emitted through a smoke-stack 11 meters above ground. The rollers are cleansed with organic solvents. In three of the rolloffsetpresses the cleansing is done automatically and in the fourth manually. Media printing The department has manual and electric repro- and composing equipment, and a Misomex plate copying machine. The company use graphic material as film, developer and fixing-bath. At the department there is also equipment for test printing and a coal filter which reduces the emission of organic solvents. The equipment used is 2 pce Scanner Crosfield used for separating colours 1 pcs Misomex, plate copying machine 1 pcs Scitex assembler used for putting text and pictures together 4 pcs film developers 1 pcs filmutkörare Electrical/mechanical workshop In the workshops mostly service- and repairing work is done. The equipment used are for example lathes, cutters, drilling-machines and some welding units. Alkaline cleaners are used. Water is taken from the pipeline of the local water purification plant, and the waste water is led to the sewage treatment works. The surface water is led to Mölndalsån.

System Boundaries	
Nature Boundary	The company is not obligated to state other emission- or waste substances than the Swedish Environmental Protection law requires. Measurements have been done regarding emissions of CO_2 and NOx but an amount per ton printed paper can not be calculated from the information in the environmental report. For more information about the emissions see''about data''.
Time Boundary	The company is obligated to write an Environmental report once every year. Though the legislated limits can be changed only if the activity is changed.
Geographical Boundary	Sweden
Other Boundaries	The company states that they use district heating, but is not able to account for how much. The environmental report states that the company has some industrial waste, consisting of scrap-steel, wood and refuse, but they are not able to account for the amount The scrap-steel is recycled by Stena Metall Återvinning AB. The wood is splintered at Sävenäs. The refuse is combustioned at Sävenäs sopförbränning.

Date concieved: 1996-10-07 Data type: Unspecified Method: The amount in the table has been calculated from values from the environmental report regarding the Ag contents per liter waste water from the developers, how many films that are developed and the amount of waste water from every film developed. Notes: The rinsing water from the developing is contaminated with Ag. The three developing machines gave the following contributions to the contamination during 1996 : Dupont 5,63% Kodak 58,6% Plate developer 35,7%	Output	Emission	Ag	0.216268293			mg	Water	
Date concieved: 1996 Data type: Estimated Method: The hydrocarbon amounts were measured during 24 hours, and knowing this an estimation for the whole year has been done. It is based on the following assumption about the hours the plants have been in operation: catalyst 16 h / day, 5 days/week, 49 weeks/year cole filter 2 h / day, 5 days/week, 49 weeks/year general ventilation 24 h / day, 7 days/week, 52 weeks/year Another assumption that has been made is that the solvents contents on the weekends and the hollidays are the same as during the night of measuring. This assumption is probably rather on the large side, because it seems lightly that the hydrocarbon contents are lower during these periods. The approximation regarding the amount for the whole year based on measurements during just 24 hours is not very certain. The extent of the production at the time for measuring does not coinside with the average extent of production. In acount to this another approximation has to be done, which makes the estimation even more	Output	Emission	Hydrocarbon	0.00014878			tonne	Air	

uncertain. The taking and analysing of specimens is done by the company ÅF-IPK AB, Kvarnbergsgatan 2, Box 1551, 401 51 Göteborg, Sweden, Phone number +46 (0)31 7431000. The amount of total hydrocarbon is measured with a devise which detects flam ionization. The ionization causes a signal, in the detector. The signal is approximately proportiunal to the amount of carbon, which through conbustion becomes carbon dioxide. This method is commonly used, and found to be relyable. It is also one of the few that allows continuous determination of the variation of the carbon content. Different carbon combines give different signal levels, because of the carbon's bond. This gives an error to the result. The instrument gives readings in parts per million. To get the reading in mg/m3 one multiplies with the mole mass of the substance in question and devides with the number of carbon atoms in 1 m3 air. The instrument used is Bernard Atomic 3005, and it has been calibrated with a known sample. The taking of specimens were done during W23 and W50. The level of production were not the same on two occations. Also the flow of gas and its temperature were measured during these weeks, so that the concentration could be converted to an amount. The flow of gas is measured by a Pitot tube and a micromanometer. The temperature is measured by thermal converter. Notes: The emission of hydrocarbon has been measured at the catalyst (1), the cole filter (2) and the general ventilation (3). A hydrogen content has also been detected which comes from not confirmed sources (4). The different sourses make the following contributions to the contamination. 1. 16,9% 2. 4,23% 3. 76,3% 4. 2,54%

About Inventory

Publication	Environmental report from Elanders Wezäta AB for 1996, The Board of County in Göteborg and Bohus The Environmental Administration in the municipality of Göteborg. The Environmental Administration in the municipality of Göteborg. -- Data documented by: Maria Erixson and Sara Ågren, project employed for the database projet at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	To show the environmental load
General Purpose	The purpose of the Environmental report is to be the base for permission trial of activities that is harmful to the environment and further to make shore that the company comply with the decision.
Detailed Purpose	To control that the legislated limits are not exceeded.
Commissioner	- The Environmental Administration in the municipality of Göteborg Box 360 401 25 Göteborg Sweden.
Practitioner	Rössum, Thor VD - Elanders Wezäta AB Grafiska vägen 22 402 22 Göteborg Sweden.
Reviewer	- The Environmental Administration in the municipality of Göteborg Box 360 401 25 Göteborg Sweden
Applicability	There is little information about what kind of prints that are made by the company. For more information contact the company.
About Data	Measurements have been done regarding emissions of CO_2 and NO_x but an amount per ton printed paper can not be calculated from the information in the environmental report. CO_2 content has been measured in the outgoing air at the catalytic oxidation plant (1) and the thermal combustion plant (2). The CO_2 content in the air was at (1) 0,54% and at (2) 1,7%, in account of the whole production. The flows at the sites were also measured and the results were at (1) 5150 m3/h and at (2) 3700 m3/h. Knowing the flow one can calculate the amount CO_2 per hour, but the total amount for 1996 is impossible to calculate, because one can not from the environmental report get the information about how many hours the plants were in operation during 1996. The CO_2 contents were measured with an IR instrument of Binos type. The range of measurement of the instrument for CO_2 is 0-20%. The instrument has been calibrated with

	a gas, which contents are known (CO2=14,9vol%). The margin of error is +/- 2%. The emission of NOx during 24 hours was at the time of taking the spiecement 2,738 g in account of the whole production that day. There is no information pointing at the fact that the extent of the production this day was characteristic for the whole year. The total amount for 1996 is impossible to calculate, because one can not, from the environmental report, get the information about how many days the thermal combustion plant was in operation during 1996. The measuring was done in the following way. Air was continuously sucked through a gas preparation system, which dryes the gas. The NOx contents was then determined by a instrument (Binos), which registrats the contents continuously. The NO is detected with IR-spectrophotometry and NO2 with UV-spectrophotometry. The range of measurement is 0-300 ppm or 0-1000 ppm for NO and 0-50 ppm or 0-150 ppm for NO2. The instrument is calibrated with calibrating gas, which has the contents 906 ppm NO and 120 ppm NO2. The margin of error is +/- 2% for air (zero gas).

Technical system description	Waste-oil and oil emulsions are delivered to Reci's facility in Halmstad. The recieved amount fluctuates during the years. During 1997 the recieved amount of waste oil was 54 748 m3. At the facility the waste-oil is processed under the influence of heat and mechanical work. The oil is thereby purified from water and some pollution. The processed oil is sold as fuel oil, mainly to the cement industry and to power plants. Oil treatment facility The waste-oil is delivered by boat, ship or truck. It is sorted according to content and stored in cisterns. By heating of the oil, water and solid pollutant are derived. Heat to the process is delivered from an oil-fuelled boiler. The water goes into the water treatment facility and the solid pollutant sediments at the bottom of the tank (oil-sludge). If the oil contains light fractions or water that can not be separated from the oil by the influence of gravitation it is treated in a separate tank. At a temperature of 120-130ºC water and distillate is separated and the distillate is gathered in an accumulation tank. Emulsions are split up by heat and chemicals. Derived oil is treated as waste-oil and the water is treated in the internal water treatment facility. Water from the facility's drainage area is led to the water treatment facility in the surface water system. (Treatment of light fractions and emulsions are not part of the studied system) The produced oil is then, after filtration, pumped to an accumulation cistern for further transportation to a purchaser. Scrap derived from filtering is sent to Sävenäs, a waste fuelled power plant. To control the process the water content is analysed with the Karl-Fisher method. This generates a small quantity of COD-sludge. A sample is collected on each delivery. The sample is analysed respecting among other things PCB. COD-sludge and derived sludge from sedimentation in the oil tanks is transported to SAKAB for destruction. Water treatment facility The plant is divided in four main parts pre-precipitation, biological treatment, after-precipitation and UF/RO filtration. Chemicals are added during the pre-precipitation to split the incoming waste product. Oil and oil-sludge are separated before the water is pumped to tanks. The separated oil is sent to the accumulation tank and the oil-sludge is handled as above. In the tanks the water is biologically treated alternately by aerobe and anaerobe steps for twelve days. After the last step in biological treatment the water is pumped to the lamella separator where the clusters are separated. The water is then sent to the UF/RO part, where the water is filtrated through an ultra filter and treated with inverted osmoses. The filters are cleansed with acid- and alkaline detergents, which dissolves among other things salts. The rejected wastewater is pumped back to be sent through the UF/RO part again. The treated water is led to the nearest recipient, the Halmstad harbour. The quantity of outflow is measured and the emissions controlled according to Swedish standard. The accumulated clusters from the water treatment process are send to Reci's facility at Skarvik in Göteborg. The waste, named water-sludge, is de-watered and deposited at Torsviken in Göteborg.

System Boundaries	
Nature Boundary	Resources that are not seen as limited in Sweden are neglected e.g. land usage and fresh water. The electricity utilised by the system is only seen as a resource and the origin is not interpreted. The company is legislated to measure the following emissions: COD BOD-7 Sulphid Phenol Oil Cd Pb Cr Zn Ni
Time Boundary	The study only deals with retrospective data and no attempts are made to predict future events or conditions. 1997 is assumed as a suitable time frame to collect and interpret data.
Geographical Boundary	The geographical boundary for the converting of waste-oil is set to Sweden.
Other Boundaries	Emissions caused by treating oil- and water-sludge are not accounted for at Reci Halmstad as this is done at external plants. The phosphoric acid and the NaOH are supposed to leave with the water-sludge and are therefore not estimated as emissions at Reci Halmstad. The de-greasing agent leaves with

	the oil sludge, combusted at SAKAB, and is therefore not estimated as an emission at Reci Halmstad. The impact caused by the substances should though be taken under consideration when treated at Reci Göteborg and SAKAB. The amount of metals in the chemical Alpoclar 200 is so low that their impact per functional unit is neglected. No measurable emission from the cisterns to the air has occurred. · No spill occurs in the plants. · The loading and unloading step is neglected in terms of consuming resources or emitting outputs. The environmental impact from capital goods and activities serving the process are neglected e.g. personell, infrastructure and facilities. Moreover, maintenance and wear down of the system are neglected.
Allocations	The plant treats both waste-oil and emulsions so the emissions had to be allocated. Emissions are allocated according to the relative oil content of the substance. This approach is conducted as the pollutants are believed to origin from the oil. The waste-oil generally contains 70 % oil and the emulsions about 5 %. This means that the waste oil contributes with 70 % oil of total amount received and the emulsions with 5 % of total amount emulsions received. Thereby is waste-oil contributing with 96.9% to the total amount of the extracted oil, and should be accounted for this amount of the total emissions. This is calculated as follows: Waste-oil Amount received: 40 354 m3 Oil contents: 70% Pre-treated waste-oil Amount received: 14 394 m3 Oil contents: 85 % Emulsion Amount received: 25 701 m3 Oil contents: 5 % (40 354*0,70+14 394*0,85)/(40 354*0.70+14 394*0,85+25 701*0,05)=0,969

Date concieved: 1997 Data type: Economical information Method: Total amount used 10044 kg. Literature: The environmental report of 1997 for Reci Industri Halmstad. Product information for Alpoclar 200 from MB-Sveda AB. Notes: Alpoclar200 (polyaluminium chloride) is used in the pre-precipitation step at the water treatment facility. The chemical is supposed to leave with the treated water. Salesman: MB-Sveda Ltd Box 4072 203 11 Malmö Phone: +46 -40 35 28 00 Content: Water 60-70% Assay Al203 17-18 wt% Cl 21-22 wt% S04 1,0-1,5 wt% Sb 0,1 ppm (max) As 0,1 ppm (max) Cd 1,0 ppm (max) Cr 2,0 ppm (max) Cu 1,0 ppm (max) Pb 1,0 ppm (max) Fe 75,0 ppm (max) Mn 5,0 ppm (max) Hg 0,1 ppm (max) Ni 5,0 ppm (max) Zn 5,0 ppm (max) Se 0,5 ppm (max)	Input	Refined resource	Alpoclar 200	0.2744			kg	Technosphere	Sweden
Date concieved: 1997 Data type: Economical information Method: Totally was 2040 litres used. Literature: Environmental report of 1997 for Reci Industri Halmstad. Product information from Skandinaviska oljecentralen. Notes: The degreasing agent (Kallavfettningsmedel) is used to clean the tanks. It leaves with the derived oil sludge. Salesman: Skandinaviska Oljecentralen Stillefors 55614 Jönköping Sweden Phone: +46 -36 18 60 60 Content: Naphta 95-100% Oleylaminetoxilat 0,1-1,0% Dipropylenglykolmetyleter 0,1-1,0%	Input	Refined resource	Degreasing agents	0.0557			l	Technosphere	Sweden
Date concieved: 1997 Data type: Economical information Method: Electricity. Total usage 2878 MWh. Literature: Environmental report of 1997 for Reci Industri Halmstad	Input	Refined resource	Electricity	78.62			kWh	Technosphere	Sweden
Date concieved: 1997 Data type: Economical information Method: 1559 m3 fuel oil (Eldningsolja 4) has been used. Literature: Environmental report of 1997 for Reci Industri Halmstad Notes: The fuel oil is used in oil-fuelled boiler to heat up the waste-oil and emulsions.	Input	Refined resource	Fuel oil	0.0426			m3	Technosphere	Sweden
Date concieved: 1997 Data type: Economical information Method: 9048 kg was used in 1997. Literature: Environmental report of 1997 for Reci Industri Halmstad Notes: HCl (30%) is used as a detergent when the filters are cleaned in the UF/RO facility. It	Input	Refined resource	HCl	0.2472			kg	Technosphere	Sweden

is supposed to leave with the treated water.									
Date concieved: 1997 Data type: Economical information Method: Totally 98629 kg used. Literature: Environmental report of 1997 for Reci Industri Halmstad Notes: NaOH is used to adjust the pH-level in the biological treatment step at the water treatment facility. It is supposed to leave with the water sludge.	Input	Refined resource	NaOH	2.694			kg	Technosphere	Sweden
Date concieved: 1997 Data type: Economical information Method: Totally 1077 kg used Literature: Environmental report of 1997 for Reci Industri Halmstad Notes: Nitric acid, HNO3, is used as a detergent when cleaning the filters at the UF/RO facility. It is supposed to leave with the treated water.	Input	Refined resource	Nitric acid	0.0294			kg	Technosphere	Sweden
Date concieved: 1997 Data type: Economical information Method: Totally where 7255 kg used. Literature: Environmental report of 1997 for Reci Industri Halmstad Notes: Phosphoric acid (75%). The acid is used in the biological treatment of the wastewater as nutritive salt. The phosphoric acid is supposed to leave with the water sludge.	Input	Refined resource	Phosphoric acid	0.1982			kg	Technosphere	Sweden
Date concieved: 1997 Data type: Economical information Method: Total amount used 56356 kg. Literature: Environmental report of 1997 for Reci Industri Halmstad. Product information for PIX 111 from Wretman & Söner AB. Notes: PIX 111 (FeCl-solution) is used in the pre-precipitation step at the water treatment facility. The chemical is supposed to leave with the treated water. Salesman: Wretman & Söner Ltd Box 2040 183 02 Täby Content: Fe(III) 13,7 +/-0,2 % Cl 26-28%	Input	Refined resource	PIX 111	1.540			kg	Technosphere	Sweden
Date concieved: 1997 Data type: Unspecified, guesstimate Method: Total amount used 263 kg. Literature: The environmental report of 1997 for Reci Industri Halmstad. Product information for Sedipur CF 104 from MB-Sveda AB Notes: The polymer, Sedipur Cf 104, is used in the pre-precipitation step at the water treatment facility. The polymer is very soluble in water and is therefore supposed to leave with the water. Salesman: MB-Sveda AB Box 4072 203 11 Malmö Phone: +46 -40 35 28 00 Content: Akrylamid <0,1%	Input	Refined resource	Sedipur Cf 104	0.0070			kg	Technosphere	Sweden

Dimetylaminoakrylat unspecified amount. The akrylamid is very biologically decomposeable (Oecd-test 301C: 73% after 14 days). Since it takes about 12 days for the water to leave the biological part of the water treatment facility, no akrylamid is supposed to be measurable in the outflowing water. As the amount of dimetylaminoakrylat is unspecified and no other subtances are presented, Sepidur Cf 104 is supposed to contain up to 100% of dimetylaminoakrylat.									
Date concieved: 1997 Data type: Economical information Method: Total amount used 150 litre. Literature: Environmental report of 1997 for Reci Industri Halmstad Notes: Natriumhypoklorit (Swedish name) is used as a detergent when cleaning the filters at the UF/RO facility. It is supposed to leave with the treated water.	Input	Refined resource	Sodiumhypoclorite	0.0041			l	Technosphere	Sweden
Date concieved: 1997 Method: Totally where 2080 litre used during 1997. Used transfer oil is treated as waste-oil. Literature: Environmental report of 1997 for Reci Industri Halmstad. Bengt Borg production manager Reci Industri Halmstad. Notes: The transfer oil (Mobiltherm 605) is used to transfer heat from the powerplant to the tanks where oil and emulsions are heated.	Input	Refined resource	Transformer oil	0.0568			l	Technosphere	Sweden
Date concieved: 1997 Data type: Economical information Method: Total amount used 2700 litre. Literature: Environmental report of 1997 for Reci Industri Halmstad. Product information about TUFF 100 from Westlund processteknisk AB Notes: Alkaline detergent,TUFF 100, is used in the cleaning of the UF/RO filters. It is supposed to leave with the treated water. Salesman: Westlund processteknisk AB Vargmötesvägen 20 186 30 Vallentuna Sweden Phone: +46 -8 511 763 50 Content: Ka-lye 20-25 % Na-glukonat 4-7 % NTA-solution(48%) 3-5 % Tridecylalkoholetoxilat 10-15 % Na-kaprylaminodipropionat 1-5 %	Input	Refined resource	TUFF 100	0.074			l	Technosphere	Sweden
Date concieved: 1997 Data type: Economical information Method: The amount recieved is measured when pumped to the reception tanks. Total amount received; 54 748 m3. the water content is approximately at an average of 30%. Literature: Environmental report of 1997 for Reci Industri Halmstad Bengt Borg	Input	Refined resource	Waste oil	1.483			m3	Technosphere	Sweden

production manager Reci Industri Halmstad.									
Date concieved: 1997 Data type: Calculated Method: According to the ''Combustion of oil'' report in SPINE 0,007 g ashes per MJ fuel oil is emitted. The fuel oil used at Halmstad has 41 MJ/kg 950 kg/m3. (Anders Edholm) Total amount fuel oil used is 1559 m3. (Environmental report) This brings the total amount of emitted ashes to about 425 kg. Literature: ''Combustion of oil'' SPINE-report. Environmental report of 1997 for Reci Industri Halmstad. Emission calculations for Eo4 by Anders Edholm Reci Industri AB. Notes: Emitted with the unpurified fumes from the combustion of oil.	Output	Emission	Ashes	11.61			g	Air	Sweden
Date concieved: 1997 Data type: Calculated Method: Based on the resource use. As the value was presented as an interval in the product information, a geometrical average has been chosen. Literature: The environmental report of 1997 for Reci Industri Halmstad. Product information for Alpoclar 200 from MB-Sveda AB. Notes: Assay Al204 chemical in Alpoclar 200 The content of Alpoclar 200 is stated abowe, where it is regarded to as an resource inflow.	Output	Emission	Assay Al 204	0.048			kg	Ocean	Sweden
Date concieved: 1997 Data type: Monitored data, discrete Method: A sample proportional to the flow is taken once a month. This is done according to the SIS-standard SS 02 81 52.(Control program) The average value of Cd in the treated water was 0,0005 mg/l. The maximum value was 0,0012 mg/l. Total outflow of water was 43 169 m3 during the year. Total amount of Cd was aproximately 0,014 kg. (Environmental report) Literature: Environmental report of 1997 for Reci Industri Halmstad. Control program for Reci Industri Halmstad. Notes: Leaves with the outflow of treated water into the harbour basin.	Output	Emission	Cd	0.0004			g	Ocean	Sweden
Date concieved: 1997 Data type: Calculated Method: Based on the resource use. As the values was presented as intervals in the product information, geometrical averages has been chosen. Literature: The environmental report of 1997 for Reci Industri Halmstad. Product information for Alpoclar 200 from MB-Sveda AB. Product information for PIX 111 from Wretman & Söner AB. Notes: Cl substance in Alpoclar 200 and PIX 111. The contents of Alpoclar 200 and PIX11 are	Output	Emission	Cl	474.69			g	Ocean	Sweden

stated above, where they are regarded to as resource inflows.									
Date concieved: 1997 Data type: Calculated Method: Some carbon in the fuel oil is supposed to emit as CO Amount of carbon: 950 kg/m3 87,1 weight% 827,45 kg C/m3 (Anders Edholm) Oil consumed: 1559 m3 (Environmental report) According to a report in SPINE ''Combustion of oil'' carbon is emitted as HC 0,013 g/MJ CO2 75,8 g/MJ CO 0,013 g/MJ. Based on the molar weight and the assumption that hydrocarbons have a neclectable amount of hydrogen (weight percentage), some 0,0269% of the total amount of carbon will emit as CO. This brings the total emission of CO to about 810 kg/year. Literature: Environmental report of 1997 for Reci Industri Halmstad. ''Combustion of oil'' report in SPINE Emission calculations for Eo4 by Anders Edholm Reci Industri AB. Notes: Emitted with the unpurified fumes from the internal power plant.	Output	Emission	CO	22.12			g	Air	Sweden
Date concieved: 1997 Data type: Calculated Method: Amount of carbon: 950 kg/m3 87,1 weight% 827,45 kg C/m3 (Anders Edholm) Oil consumed: 1559 m3 (Environmental report) According to a report in SPINE ''Combustion of oil'' carbon is emitted as HC 0,013 g/MJ CO2 75,8 g/MJ CO 0,013 g/MJ. Based on the molar weight and the assumption that hydrocarbons have a neclectable amount of hydrogen (weight percentage), some 99,9467 % of the total amount of carbon will emit as CO2. This brings the total emission of CO2 to about 4727930 kg/year. Total amount CO2 emitted 4730 tonnes. Literature: Environmental report of 1997 for Reci Industri Halmstad. ''Combustion of oil'' report in SPINE Emission calculations for Eo4 by Anders Edholm Reci Industri AB. Notes: Emitted with the unpurified fumes from the oil-fuelled boiler.	Output	Emission	CO2	129.16			kg	Air	Sweden
Date concieved: 1997 Data type: Monitored data, discrete Method: A sample proportional to the flow is taken once a week This is done according to the SIS-standard SS 02 81 42. (Control program) The average value of COD in the treated water was 500 mg/l. The maximum value was 567 mg/l and the minimum 418 mg/l. Total outflow of water was 43 169 m3 during the year. Total amount of COD was 42400 kg. (Environmental report) Literature: Environmental report of 1997 for Reci Industri	Output	Emission	COD	1158.3			g	Ocean	Sweden

Halmstad. Control program for Reci Industri Halmstad. Notes: Leaves with the outflow of treated water into the harbour basin.									
Date concieved: 1997 Data type: Monitored data, discrete Method: A sample proportional to the flow is taken once a month. This is done according to the SIS-standard SS 02 81 52. (Control program) The average value of Cr in the treated water was <0,002 mg/l. Total outflow of water was 43 169 m3 during the year. Total amount of Cr was approximately 0,26 kg. (Environmental report) Literature: Environmental report of 1997 for Reci Industri Halmstad. Control program for Reci Industri Halmstad. Notes: Leaves with the outflow of treated water into the harbour basin.	Output	Emission	Cr	0.007			g	Ocean	Sweden
Date concieved: 1997 Data type: Calculated Method: Based on the resource use. As the amount was unspecified an estimation has been made (see data for Sedipur Cf 104 above). Literature: The environmental report of 1997 for Reci Industri Halmstad. Product information for Sedipur CF 104 from MB-Sveda AB. Notes: Dimetylaminoakrylat (Swedish name) substance in Sedipur CF 104. The content of Sedipur Cf 104 is stated abowe, where it is regarded to as an resource inflow.	Output	Emission	Dimetylaminoakrylat	0.007			kg	Ocean	Sweden
Date concieved: 1997 Data type: Calculated Method: Based on the resource use. As the value was presented as an interval in the product information, an average value has been chosen. Literature: The environmental report of 1997 for Reci Industri Halmstad. Product information for PIX 111 from Wretman & Söner AB. Notes: Fe (III) substance in PIX 111. Leaves with the treated water. The content of PIX 111 is stated abowe, where it is regarded to as an resource inflow.	Output	Emission	Fe	210.9			g	Ocean	Sweden
Date concieved: 1997 Data type: Calculated Method: Amount of carbon: 950 kg/m3 87,1 weight% 827,45 kg C/m3 (Anders Edholm) Oil consumed: 1559 m3 (Environmental report) According to a report in SPINE ''Combustion of oil'' carbon is emitted as HC 0,013 g/MJ CO2 75,8 g/MJ CO 0,013 g/MJ. Based on the molar weight and the assumption that hydrocarbons have a neclectable amount of hydrogen (weight percentage), some 0,0134 % of the total amount of carbon will emit as HC. This brings the total	Output	Emission	HC	5.11			g	Air	Sweden

emission of HC to about 187 kg/year. Literature: Environmental report of 1997 for Reci Industri Halmstad. ''Combustion of oil'' report in SPINE Emission calculations for Eo4 by Anders Edholm Reci Industri AB. Notes: Emitted with the unpurified fumes from the internal power plant.									
Date concieved: 1997 Data type: Economical information Method: Based on the resource used. Literature: The environmental report of 1997 for Reci Industri Halmstad. Notes: See above HCl resource.	Output	Emission	HCl	74.15			g	Ocean	Sweden
Date concieved: 1997 Data type: Calculated Method: Based on the resource use. As the value was presented as an interval in the product information, an average value has been chosen. Literature: The environmental report of 1997 for Reci Industri Halmstad. Product information for TUFF 100 from Westlund processteknik AB. Notes: KOH chemical in TUFF 100, leaves with the outflowing water. The content of TUFF 100 is stated abowe, where it is regarded to as an resource inflow.	Output	Emission	KOH	0.0166			l	Ocean	Sweden
Date concieved: 1997 Data type: Economical information Method: Based on the resource use. Literature: The environmental report of 1997 for Reci Industri Halmstad. Notes: Natriumhypoclorit (NaClO) leaves with the treated water. Supposed to be relative harmless since it can be used to disinfect food products or be used in swimming-pools.	Output	Emission	NaClO	0.004			l	Ocean	Sweden
Date concieved: 1997 Data type: Monitored data, discrete Method: A sample proportional to the flow is taken once a month. This is done according to the SIS-standard SS 02 81 52. (Control program) The average value of Ni in the treated water was 0,05 mg/l. The maximum value was 0,055 mg/l and the minimum 0,017 mg/l. Total outflow of water was 43 169 m3 during the year. Total amount of Ni was 7,12 kg. (Environmental report) Literature: Environmental report of 1997 for Reci Industri Halmstad. Control program for Reci Industri Hamstad. Notes: Leaves with the outflow of treated water into the harbour basin.	Output	Emission	Ni	0.1945			g	Ocean	Sweden
Date concieved: 1997 Data type: Economical information Method: Based on the resource	Output	Emission	Nitric acid	29.42			g	Ocean	Sweden

used. Literature: The environmental report of 1997 for Reci Industri Halmstad. Notes: HNO3 see above Nitric acid, resource.									
Date concieved: 1997 Data type: Calculated Method: According to a report from Studsvik ''NOx-utsläpp från oljeeldade pannor'' (Studsvik/E2-80/91) the emission is approximately 130 mg/MJ for Eldningsolja 4. Density: 950 kg/m3 Calorific equivalent: 41 MJ/kg Amount of energy supplied: 950*41 = 38950 MJ/m3 Amount of emitted NOx: 38950*130 = 5,06 kg/m3 (Anders Edholm) Oil consumed: 1559 m3. (Environmental report) Total amount NOx emitted 7884,54 kg. Literature: Environmental report of 1997 for Reci Industri Halmstad. Emission calculations for Eo4 by Anders Edholm Reci Industri AB. Notes: Emitted with the unpurified fumes from the oil-fuelled boiler.	Output	Emission	NOx	215.51			g	Air	Sweden
Data type: Calculated Method: Based on the resource use. As the value was presented as an interval in the product information, an average value has been chosen. Literature: The environmental report of 1997 for Reci Industri Halmstad. Product information for TUFF 100 from Westlund processteknik AB. Notes: Nta-solution (re-calculated to 100%) chemical in TUFF 100, leaves with the outflowing water. The content of TUFF 100 is stated abowe, where it is regarded to as an resource inflow.	Output	Emission	NTA-solution	0.0014			l	Ocean	Sweden
Date concieved: 1997 Data type: Monitored data, discrete Method: A sample proportional to the flow is taken once a week This is done according to the SIS-standard SS 02 81 45. (Control program) Literature: Environmental report of 1997 for Reci Industri Halmstad. Control program for Reci Industri Halmstad Notes: Leaves with the outflow of treated water into the harbour basin. Total outflow of water was 43 169 m3 during the year. Total amount of oil in the water was 8,96 kg. (Environmental report)	Output	Emission	Oil (aq)	0.2448			g	Ocean	Sweden
Date concieved: 1997 Data type: Calculated Method: The amount of oil per litre water in the surface water system is represented in the Environmental report for Reci Industri Halmstad. The data is given as one value for every month in mg/l. To calculate the total emission of oil leaving with the surface water the amount of surface water must be known. Data about the	Output	Emission	Oil (aq)	10.23			g	Ocean	Sweden

amount of precipitation in Halmstad is taken from the report ''Växtskyddsåret 1997''. The production manager, Bengt Borg has estimated the drainage area to 500 m2. The calculated amount of oil leaving with the surface water is 374,375 g/year. Month mm mg/l mg oil precipitation (oil/water) Oct 65 1.3 42250 Nov 65 1.55* 50375 Dec 30 1.8 27000 Jan 15 1.75* 13125 Feb 90 1.7 76500 Mar 25 1.55* 19375 Apr 45 1.4 31500 May 80 0.7 28000 Jun 40 0.3 6000 Jul 110 0.7* 38500 Aug 25 0.7* 8750 Sep 60 1.1 33000 Calculation: drainage area*mm precipitation*mg/l=mg oil emitted per month Values followed by * is estimated as an average value from the two closest months. This is done when data is lacking for the specific month. Precipitation data for Oct Nov Dec is taken from 1996, but are supposed to be representative for the same period of 1997. Literature: The environmental report of 1997 for Reci Industri Halmstad. Bengt Borg, production manager Reci Industri Halmstad. The report ''Växtskyddsåret 1997 Halland Skåne Blekinge'' published by: Växtskyddscentralen Box 12 230 53 Alnarp Sweden Notes: The precipitation data is taken from a table in the report ''Växtskyddsåret''. The data may therefore contain reading errors. It is not known how or where the data has been measured. The area of drainage is a coarse estimation. No infiltration to the ground or evaporation in the drainage area is supposed to take place, all precipitation leaves as oil contaminated surface water.									
Date concieved: 1997 Data type: Calculated Method: According to the ''Combustion of oil'' report in SPINE 0,03 g particulates per MJ fuel oil is emitted (data is valid for a smaller sized installation). The fuel oil used at Halmstad has 41 MJ/kg 950 kg/m3. (Anders Edholm) Total amount fuel oil used is 1559 m3.(Environmental report) This brings the total amount of emitted particulates to about 1821,7 kg. Literature: ''Combustion of oil'' SPINE-report Emission calculations for Eo4 by Anders Edholm Reci Industri AB. Environmental report of 1997 for Reci Industri Halmstad. Notes: Emitted with the unpurified fumes from the internal power plant.	Output	Emission	Particulates	49.77			g	Air	Sweden
Date concieved: 1997 Data type: Monitored data, discrete Method: A sample proportional to the flow is taken once a month. This is done according	Output	Emission	Pb	0.0019			g	Ocean	Sweden

to the SIS-standard SS 02 81 52. (Control program) The average value of Pb in the treated water was <0,002 mg/l. Total outflow of water was 43 169 m3 during the year. Total amount of Pb was 0,07 kg. (Environmental report) Literature: Environmental report of 1997 for Reci Industri Halmstad. Control program for Reci Industri Halmstad. Notes: Leaves with the outflow of treated water into the harbour basin.									
Date concieved: 1997 Data type: Monitored data, discrete Method: A sample proportional to the flow is taken once a week This is done according to the SIS-standard SS 02 81 28. (Control program) The average value of destillable phenols in the treated water was 2,2 mg/l. Total outflow of water was 43 169 m3 during the year. Total amount of destillable phenols was 42 kg. (Environmental report) Literature: Environmental report of 1997 for Reci Industri Halmstad. Control program for Reci Industri Halmstad. Notes: Leaves with the outflow of treated water into the harbour basin.	Output	Emission	Phenol	1.13			g	Ocean	Sweden
Date concieved: 1997 Data type: Calculated Method: Sulphur in the fuel oil is supposed to emit as SO2 Amount of sulphur: 950 kg/m3 <0.3 weight% S=< 2,85 kg/m3 this leads to an emission of 5,70 kg/m3 SO2. (Anders Edholm) Oil consumed: 1559 m3. (Environmental report) Total amount SO2 emitted 8886 kg. Literature: Emission calculations for Eo4 by Anders Edholm Reci Industri AB. Environmental report of 1997 for Reci Industri Halmstad. Notes: Emitted with the unpurified fumes from the oil-fuelled boiler.	Output	Emission	SO2	242.77			g	Air	Sweden
Date concieved: 1997 Data type: Calculated Method: Based on the resource use. As the value was presented as a interval in the product information, an geometrical average has been chosen. Literature: The environmental report of 1997 for Reci Industri Halmstad. Product information for Alpoclar 200 from MB-Sveda Ltd Notes: SO4 substance in Alpoclar 200 The content of Alpoclar 200 is stated abowe, where it is regarded to as an resource inflow. chosen. Literature: The environmental report of 1997 for Reci Industri Halmstad. Product information for TUFF 100 from Westlund processteknik AB. Notes: Natriumglukonat (Swedish name) chemical in TUFF 100, leaves with the outflowing water. The content of TUFF 100 is stated abowe, where it is regarded to as an resource inflow. Natriumglukonat is supposed to be relatively harmless as it can be found in food products.									
Date concieved: 1997 Data type: Calculated Method: Based on the resource use. Literature: The environmental report of 1997 for Reci Industri Halmstad. Product information for TUFF 100 from Westlund processteknik AB. Notes: Natriumkaprylaminodipropionat (Swedish name) chemical in TUFF 100, leaves with the outflowing water. The content of TUFF 100 is stated abowe, where it is regarded to as an resource inflow.	Output	Emission	Sodiumkaprylaminodiproponate	0.0092			l	Ocean	Sweden
Date concieved: 1997 Data type: Random samples Method: A sample test is done once a week according to the SIS-standard SS 02 81 17. (Control program) The average was less than 0,09 mg/l of treated water. The minimum value was <0,03 mg/l and the maximun value <0,35 mg/l. Total outflow of water was 43 169 m3 during the year. Total amount of sulphide was 2 kg. (Environmental report) Literature: Environmental report of 1997 for Reci Industri Halmstad. Control program for Reci Industri Halmstad. Notes: Leaves with the outflow of treated water into the harbour basin.	Output	Emission	Sulphid	0.0563			g	Ocean	Sweden
Date concieved: 1997 Data type: Monitored data, discrete Method: A sample proportional to the flow is taken once a week This is done according to the SIS-standard SS 02 81 12. (Control program) Total outflow of water was 43 169 m3 during the year. Total amount of suspended materials was 3119 kg. (Environmental report) Literature: Environmental report of 1997 for Reci Industri Halmstad. Control program for Reci Industri Halmstad. Notes: Leaves with the outflow of treated water into the harbour basin.	Output	Emission	Susp solids	85.21			g	Ocean	Sweden
Data type: Calculated Method: Based on the resource use. As the value was presented as an interval in the product information, an average value has been chosen. Literature: The environmental report of 1997 for Reci Industri	Output	Emission	Tridecylalkoholetoxilat	0.009			l	Ocean	Sweden

Halmstad. Product information for TUFF 100 from Westlund processteknik AB. Notes: Tridecylalkoholetoxilat (Swedish name) chemical in TUFF 100, leaves with the outflowing water. The content of TUFF 100 is stated abowe, where it is regarded to as an resource inflow.									
Date concieved: 1997 Data type: Monitored data, discrete Method: A sample proportional to the flow is taken once a month. This is done according to the SIS-standard SS 02 81 52. The maximum value was 0,037 mg/l and the minimum <0,006 mg/l. Total outflow of water was 43 169 m3 during the year. Total amount of Zn was 2,09 kg. (Environmental report) Literature: Environmental report of 1997 for Reci Industri Halmstad. Control program for Reci Industri Halmstad. Notes: Leaves with the outflow of treated water into the harbour basin.	Output	Emission	Zn	0.057			g	Ocean	Sweden
Date concieved: 1997 Data type: Economical information Literature: Environmental report of 1997 for Reci Industri Halmstad Notes: The systems functional unit. The processed oil is sold as fuel oil, mainly to the cement industry and to power plants.	Output	Product	Converted fuel oil	1			m3	Technosphere	Sweden
Date concieved: 1997 Data type: Unspecified Method: COD-sludge originates when the water contents is analysed with Karl-Fisher. Total amount 20 kg/year. Literature: Bengt Borg production manager Reci Industri Halmstad..	Output	Residue	COD-sludge	0.0005			kg	Technosphere	Sweden
Date concieved: 1997 Data type: Calculated Method: The amount of oil sludge that results from the processing of waste oil is calculated as 0,25% of the delivered waste oil from Stockholm and Göteborg and 0,75% of the surplus delivered. Total amount sedimentated 237,065 m3. Literature: Bengt Borg production manager, Reci Industri Halmstad. Notes: The oil sludge ,caused by sedimentation in the tanks, is derived when the tanks are cleaned. As this is not an every-year-procedure the amount sedimentated per year is estimated as above. The oil sludge is transported to SAKAB for destruction. Amount of pollutants in the oil sludge (Data from a sample taken 29/4-91) Sulphur 2,0 weight% Chloride 0,13 weight% Si 23200 mg/kg V 90 mg/kg Hg 3,5 mg/kg Al 3400 mg/kg Pb 800 mg/kg Fe 28800 mg/kg Cd <2 mg/kg Ca 4300 mg/kg Cu 1300 mg/kg Cr 400 mg/kg Ni	Output	Residue	Oil-sludge	0.0066			m3	Technosphere	Sweden

300 mg/kg Zn 5500 mg/kg The oil sludge also contains the degreasing agent Kallavfettningsmedel (see above).									
Date concieved: 1997 Data type: Unspecified, expert outspoke Literature: Bengt Borg, production manager, Reci Industri Halmstad. Notes: The scrap, derived from filtering, is transported to Sävenäs for combustion. Sävenäs is a waste fuelled power plant.	Output	Residue	Scrap	0.00026			tonne	Ground	Sweden
Date concieved: 1997 Data type: Unspecified Method: Total amount 501 m3. (Environmental report) Literature: Environmental report of 1997 for Reci Industri Halmstad. Bengt Borg production manager, Reci Industri Halmstad . Notes: Water sludge, caused by the biological step at the water treatment facility. It is transported to Reci's facility in Göteborg for de-watering and later deposition at Torsviken. Composition of the water sludge Dry substance 207 g/kg Pb 26 mg/kg Cu 120 mg/kg Cr 17 mg/kg Ni 30 mg/kg Zn 430 mg/kg Cd 0,20 mg/kg Hg <0,05 mg/kg Chloride 1300 mg/kg The data are from a sample taken 26/11-98 (Bengt Borg)	Output	Residue	Water-sludge	0.0137			m3	Technosphere	Sweden

About Inventory

Publication	Master thesis: ''LCA on converted fuel oil'' by Daniel Strandberg and Christer Wik, MSc students Technical environmental planning, Chalmers Univeristy of Technology -- Data documented by: Daniel Strandberg and Christer Wik, MSc students, Technical Environmental Planning, Chalmers University of Technology Documentation reviewed and classified by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	Internal use at Reci Industri
General Purpose	The objective of this study was to carry out a Life Cycle Assessment for converted fuel oil. The analysis involves outlining the environmental hazardous steps in the production. The result will be used internally to aid as an environmental improving guidance as well as to receive a better view of the process. Externally the result is a part of Reci's ISO 14000 certification, which acts as a guarantee to the customers. The quality of the inquiry is set due to the standards of a Master of Science thesis.
Detailed Purpose	Data about emissions from the process of converting waste-oil into fuel oil at Reci Industri Halmstad.
Commissioner	Schaff, Lars, environmental manager - Reci Industri AB Box 48047 418 21 Göteborg Sweden.
Practitioner	Strandberg, Daniel and Christer Wik - MSc students Technical Environmental Planning Chalmers University of Technology 41296 Göteborg Sweden.
Reviewer	Beckman, Torsten - Technical environmental planning Chalmers University of Technology 412 96 Göteborg Sweden
Applicability	The data are specific for processing of waste oil into fuel oil. As some of the data are allocated and some are achieved through estimations and coarse measurements the result should only be seen as an estimation of the emissions.
About Data	About data for the oil contamination in the surface water: · The precipitation data is taken from a table in the report ''Växtskyddsåret''. The data may therefore contain reading errors. It is not known how or where the data has been measured. · Some values are estimated as an average value from the two closest months. This is done when data is lacking for the specific month.

	· Precipitation data for Oct Nov Dec is taken from 1996, but are supposed to be representative for the same period of 1997. · The area of drainage is a coarse estimation. · No infiltration to the ground or evaporation in the drainage area is supposed to take place, all precipitation leaves as oil contaminated surface water. The oil-sludge, caused by sedimentation in the tanks, is derived when the tanks are cleaned. As this is not an every-year-procedure the amount that sediments per year is estimated as 0,25 % of the delivered waste-oil from Stockholm and Göteborg and 0,75 % of the surplus delivered. Mass balance · Inflow about 80 634 m3 (emulsions 25 701 m3). · Outflow is approximately 80 733 m3 When calculating the mass balance 1 ton is approximated to be equal with 1 m3 for all substances. The difference between the inflow and outflow is about 0,1 per cent. When considering our approximation and possible measurement errors it is believed to be a balance in masses. Some of the data about emissions to the air from the internal power plant has been taken from the SPINE-report ''Combustion of oil''. The data are general and no difference has been made between different types of oil.
Notes	The reviewer acted as supervisor for the Master thesis: ''LCA on converted fuel oil''

About Inventory

Publication	The Environmental Report from Götaverken Motor AB for 1996, The Environmental Administrationin the municipality of Göteborg. --- Data documented by: Maria Erixson and Sara Ågren, project employed for the database projet at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology ---
Intended User	To show the environmental load
General Purpose	The purpose of the Environmental report is to be the base for permission trial of activities that is harmful to the environment and further to make shore that the company comply with the decision.
Detailed Purpose	To control that the legislated limits are not exceeded.
Commissioner	- Swedish government via The Board of County in Göteborg and Bohus or The Environmental Administration in the municipality of Göteborg. .
Practitioner	Lindoff, Lennart - Götaverken Motor AB Box 8843 40271 Göteborg Sweden .
Reviewer	- Swedish government via The Board of County in Göteborg and Bohus or The Environmental Administration in the municipality of Göteborg.
Applicability	The extent of the production is not mentioned in the Environmental report. Because of this we have no functional unit which makes it impossible to use the data direct for life cycle analysis. Though, it is possible to get in touch with the company and try to get some more information. The function of the system and the components are not described satisfactory. For more information contact the company.

SPINE LCI dataset: Production of 0,005-0,02 mm double-rolled aluminium foil

Administrative	
Finished	Y
Date Completed	2002-05-06
Copyright	EAA
Availability	Public

Technical System	
Name	Production of 0,005-0,02 mm double-rolled aluminium foil
Functional Unit	1000 kg aluminium foil (0,005-0,02 mm)
Functional Unit Explanation	Aluminium foil with thickness between 0,005 mm and 0,02 mm.
Process Type	Gate to gate
Site	Not specified. See Geographical boundaries for further information.
Sector	Materials and components
Owner	Not specified. See Geographical boundaries for further information.
Technical system description	Aluminium foil is used in varying gauges and in a number of alloys for a variety of applications. It is available in thickness from 5 microns to 200 microns (i.e. 0,005 to 0,2 mm) and can be supplied in a range of finishes. This data set describes the production of aluminium foil in a thickness of 0,005-0,02 mm. The starting material for the production of rolled aluminium foil is aluminium slab (rolling ingot), which is first rolled into foil stock, i.e. the specific input for foil fabrication. In this documentation, the starting material is referred to as ''aluminium ingot'' when is comes from an external primary or secondary aluminium plant. It is also produced by remelting process scrap internally within this system (Ingot remelting and casting) and this input is referred to as ''casting scrap''. The included process steps are: - Aluminium foil production - 1. Sawing and scalping 2. Preheating 3. Hot rolling 4. Cold rolling foil stock 5. Cold rolling single 6. Final anneal 7. Finishing

	8. Packaging - Process scrap recycling - 9. Ingot remelting and casting Electricity production is included in the system. The process step ''Ingot remelting and casting'' is described in some further detail below. From the process steps 1-4, Sawing and scalping, Preheating, Hot rolling, and Cold rolling foil stock 643 kg scrap is going to the process step ingot remelting and casting. The process steps 5-8, Cold rolling single, Final anneal, Finishing, and Packaging contributes with additional 347 kg scrap. 44 kg scrap is recycled within the process ingot remelting and casting.

System Boundaries

Nature Boundary	--- BOUNDARIES VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- Cut-off criteria through out this inventory is basically relevance, as checked by the industry expert team monitoring the work and confirmed by reviewer I. Boustead. As a rough guideline ''less than 1% of total mass'' is applied for the inputs, i.e if the input is less than 1% of the total mass, then it is not included in the inventory table. The base for the choices of included inventory parameters is not further described in the EAA report.
Time Boundary	--- BOUNDARIES VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- The data derived from an industry survey from 1998 and includes literature data from reports dated 1998 and 1999.
Geographical Boundary	--- BOUNDARIES VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- It is not always explicit in the report where the different included process steps take place. Data may be acquired from outside of Europe, e.g. regarding ancillary processes. See litterature references (LitteratureRef) next to the flow table (FlowMetaData) for further information about the data sources for each process step.
Other Boundaries	See Nature boundaries for a specification of the cut-off criteria that has been applied. The production of primary or recycled aluminium is not included in the system.
Allocations	Allocations are not explicitly specified in the Environmental Profile Report 2000.
Systems Expansions	System expansions are not explicitly specified in the Environmental Profile Report 2000.

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, unspecified
Represents	Not relevant.
Method	PRODUCTION OF SEMI-FINISHED ALUMINIUM The data derive from an industry survey with a coverage ranging from 20% to 70%, depending on the product in question. INGOT REMELTING AND CASTING (RECYCLING OF PROCESS SCRAP) Data were obtained from aluminium-integrated cast house operations, i.e. cast houses associated with semi-finished aluminium production. The 1998 survey on semi-finished aluminium products also encompassed aluminium-integrated cast houses, with 37% coverage for the recycling of process scrap. TRANSPORTS Transport energy and air emission data have been taken from SAEFL Environmental Series 250 (1998) ''BUWAL 250'', table 16.9 ELECTRICITY For all manufacturing operations, the consumption of fossil fuels and emissions linked to electricity production was calculated according to the UCTPE 94 electrical energy model as described in BUWAL 250. Emissions from combustion only, i.e. without the precombustion contribution, have been considered where appropriate in order to make a direct comparision with the corresponding process emissions. Emission data for combustion came from a report prepared by EMPA for EEA (13 December 1997), showing the respective contributions of precombustion and combustion in 'BUWAL 250, table 16.9'. Although emissions from fuel combustion were often covered in the industry survey reporting, data calculated from BUWAL 250 were always used, inview of the fact that the survey results were not sufficiently reliable due to inconsistent use of conversion factors.
Literature Reference	---Aluminium foil production and process scrap recycling Industry survey from 1998 ---Transport energy, electricity, and air emission - SAEFL Environmental Series 250 (1998) ''BUWAL 250'', table 16.9 - EMPA report for EAA dated 27 April 1998, derived from Buwal 250 for national grid systems.
Notes	In this inventory profile it is possible to identify which process step (Aluminium foil production, Process scrap recycling) the flow is connected to, see Note-field for each specific flow. However, in order to get the numerical data devided on these two process steps, see Environmental Profile Report (EAA, 2000).

Notes: This substance derives from both the foil production and the process scrap recycling.	Output	Residue	Solid waste unspecified	21			kg	Technosphere	

About Inventory

Publication	Environmental Profile Report for the European Aluminium Industry, European Aluminium Association, April 2000 -- Data documented by: Maria Erixon, IMI, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, IMI, Chalmers University of Technology Published in SPINE@CPM: 8 May 2002 --
Intended User	LCA-practitioners.
General Purpose	The European Aluminium Association (EAA) aims to contribute to further environmental improvements in aluminium products in a life cycle concept.
Detailed Purpose	The purpose with the Environmental Profile Report 2000 is to provide LCA-practitioners with detailed and up-to-date information representing the aluminium industry activities in Europe. The purposes with formatting the Environmental Profile Report 2000 for the European Aluminium Industry to the data documentation format SPINE, according to the data documentation criteria applied at Centre for environmental assessment of Product and Material systems (CPM) are: - CPM and European Aluminium Association (EAA) are anxious to provide life cycle assessment (LCA) practitioners with accurate and up to date environmental data for aluminium production. - EAA is interested in the SPINE formatting procedure and result, as the format is a base for (and therefor somewhat similar to) the new Technical Specification in ISO, ISO 14048, regarding LCA data documentation format. - EAA is interested in the CPM data quality control and documentation criteria.
Commissioner	- EAA (European Aluminium Association) 12 Av. de Broqueville B-1150 Brussels .

Reviewer	Dr. Ian Boustead, - 2 Black Cottages West Grinstead, Horsham GB-West Sussex RH13 7BD
Applicability	--- SPECIFIC INFORMATION FOR THIS DATA SET --- ENERGY USE IN THE DIFFERENT INCLUDED PROCESS STEPS The energy directly consumed by the operations enclosed within the system bounderies, i.e. in the various process steps, are presented below. See the headline ''DATA SOURCES FOR FUELS/ENERGY PRODUCTION AND COMBUSTION'' in About Data for further information. -- Aluminium foil production--- Fuel oil (kg) 15,2 Gas (kg) 98 Electricity UCTPE* (kWh) 1780 ---Process scrap recycling--- Fuel oil (kg) 0,8 Gas (kg) 69 Electricity UCTPE* (kWh) 156 * UCTPE 94 is an electrical energy model for energy supporting all processes in this system (including transports), except electrolysis and cast house. It is described in BUWAL 250, see litterature references. --- GENERAL INFORMATION VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- RECOMMENDATIONS BY EAA WHEN USING THE DATA The data provided by the EAA members for their own process steps are the most up-to-date average data available for these processes, and it is recommended that they be used for LCA purposes. Older literature data should be disregarded, as it may no longer be representative due to technological improvements, progress in operating performance, changes with regard to raw materials or waste treatment, etc. To complete the product system inventory, data - on the production of consumer products, from semi-fabricated aluminium, - on the performance of consumer products in the use phase, and - on the recovery of scrap prior to remelting at the end of the product's useful life should be acquired. EAA recommend that these data be used in LCA studies in accordance with methodologies within the framework of the international standards in the ISO 14040-series. RELATED DATA SETS IN SPINE DATA FORMAT The data presented in the Environmental Profile Report is reformatted in to the SPINE format and structured according to the SPINE concept in as many separate activities (sub-systems) as possible. The system scope for the study as a whole is primary aluminium production, semi-finished aluminium production, and recycling. The SPINE formatting resulted in 7 activities. These activities are all published in the SPINE@CPM database. The production and recycling step are intended to be used together. For example, to obtain a cradle to gate-system for rolled aluminium sheet, the activity Primary aluminium production should be connected to the activity Production of rolled aluminium sheet. A recycling step (Aluminium recycling by refiners) could also be connected to such a system, depending on the scope. -- List of activities formatted in the SPINE-format, published in SPINE@CPM -- Primary aluminium production 1. Primary aluminium production Semi-finished aluminium product fabrication 2. Production of rolled aluminium sheet 3. Production of extruded aluminium profiles 4. Production of 0,02-0,2 mm single-rolled aluminium foil 5. Production of 0,005-0,02 mm double-rolled aluminium foil Recycling 6. Re-melting of aluminium scrap 7. Aluminium recycling by refiners Please note: The recycling process 6. Re-melting of aluminium scrap is included in the semi-finished aluminium product fabrication, i.e. activities 2-5. When designing a product system with the activities above where recycled aluminium is regarded, the activity Aluminium recycling by refiners should be used. The Re-melting of aluminium activity is only a specification if the user is specifically interested in this process step. RECYCLING RATES FOR ALUMINIUM PRODUCTS AFTER USE After use, aluminium products are a valuable re-usable resource. The European recycling

	rates for end products are currently around 95% for the automotive sector and 85% for the building sector. IMPROVEMENTS IN THE ENVIRONMENTAL PERFORMANCE OF ALUMINIUM PRODUCTS AND PROCESSES OVER THE PAST FEW YEARS Over the past few years EAA has achieved major improvements in the environmental performance of its production processes by means of the following: - improvement on existing technology - development and introduction of new technology and operations - increased recycling of all materials in the production process. Examples of major environmental improvements in aluminium products achieved over the past few years include: - weight reduction by downgauging in the packaging sector - energy savings through weight reduction and subsequent fuel reduction in the transport sector - reduction of maintenance in the building sector The previous Ecological Profile Report from EAA was published in 1996.
About Data	--- GENERAL INFORMATION VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- PRECISION According to EAA, the environmental data figures in the inventory table are usually accurate to a precision of 5%. DATA SOURCES FOR FUELS/ENERGY PRODUCTION AND COMBUSTION The electricity supply systems and fuel production and use (transport energy and emission data) have been taken from SAEFL Environmental Series 250 (1998) 'Buwal 250' and EMPA report for EAA dated 27 April 1998, derived from Buwal 250 for national grid systems. All emissions connected with total fuel consumption (i.e. production and combustion of oil, gas or coal) have been taken from SAEFL Environmental Series 250 (1998) 'Buwal 250', table 16.9. Emissions from combustion only, i.e. excluding the contribution of the production of the fuel, have been considered where appropriate in order to make a direct comparision with the corresponding process emissions. Emission data for combustion came from a report prepared by EMPA for EEA (13 December 1997), showing the respective contributions of production and combustion of fuels in 'BUWAL 250, table 16.9'. Although emissions from fuel combustion were often covered in the industry survey reporting, data calculated from BUWAL 250 were always used, in view of the fact that the survey results were not sufficiently reliable due to inconsistent use of conversion factors. REVIEW OUTSPOKE Ian Boustead has reviewed and commented on the Environmental Profile Report for the European Aluminium Industry, April 2000, which is a revision of the first Ecological Profile Report from EAA that were published in 1996. Ian Bousteds' review comments on the Environmental Profile Report for the European Aluminium Industry, April 2000: ''...I have received the detailed calculations on which this present environmental report is based. All of the queries that I raised after working through these reports were answered satisfactory.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000 ''Good-quality data were supplied by the EAA member companies, and the number of companies participating provides good coverage of the various processes, meaning that the results can be regarded as representative of the industryas a whole for the production of primary aluminium and subsequent conversion processes.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000 ''Because of the very fragmented nature of the recycling industry and wide variations in practices, it is recognised that the data presented for this sector of the industry can only be regarded as indicative. Nevertheless it is helpful to have such information from an authorative source.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000
Notes	REVIEWER Ian Boustead has reviewed and commented on the Environmental Profile Report for the European Aluminium Industry, which is a revision of the first Ecological Profile Report from EAA that were published in 1996. See AboutData for review comments.

SPINE LCI dataset: Production of 0,02-0,2 mm single-rolled aluminium foil

Administrative	
Finished	Y
Date Completed	2002-05-07
Copyright	EAA
Availability	Public

Technical System	
Name	Production of 0,02-0,2 mm single-rolled aluminium foil
Functional Unit	1000 kg aluminium foil (0,02-0,2 mm)
Functional Unit Explanation	Aluminium foil with thickness between 0,02 mm and 0,2 mm
Process Type	Gate to gate
Site	Not specified. See Geographical boundaries for further information.
Sector	Materials and components
Owner	Not specified. See Geographical boundaries for further information.
Technical system description	Aluminium foil is used in varying gauges and in a number of alloys for a variety of applications. It is available in thickness from 5 microns to 200 microns (i.e. 0,005 to 0,2 mm) and can be supplied in a range of finishes. This data set represents the describes of aluminium foil in a thickness of 0,02-0,2 mm. The starting material for the production of rolled aluminium foil is aluminium slab (rolling ingot), which is first rolled into foil stock, i.e. the specific input for foil fabrication. In this documentation, the starting material is referred to as ''aluminium ingot'' when is comes from an external primary or secondary aluminium plant. It is also produced by remelting process scrap internally within this system (Ingot remelting and casting) and this input is referred to as ''casting scrap''. The process steps are: - Aluminium foil production 1. Sawing and scalping 2. Preheating 3. Hot rolling 4. Cold rolling foil stock 5. Cold rolling single 6. Final anneal 7. Finishing 8. Packaging - Process scrap recycling 9. Ingot remelting and casting The production of electricity is included in the system. Some further details on the process step Ingot remelting and casting is given below From the process steps 1-4, Sawing and scalping, Preheating, Hot rolling, and Cold rolling foil stock 589 kg scrap is going to the process step Ingot remelting and casting The process steps 5-8 Cold rolling single, Final anneal, Finishing, and Packaging contributes with additional 234 kg scrap. 36 kg scrap is recycled within the process ingot remelting and casting.

System Boundaries	
Nature Boundary	--- BOUNDARIES VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- Cut-off criteria through out this inventory is basically relevance, as checked by the industry expert team monitoring the work and confirmed by reviewer I. Boustead. As a rough guideline ''less than 1% of total mass'' is applied for the inputs, i.e if the input is less than 1% of the total mass, then it is not included in the inventory table. The base for the choices of included inventory parameters is not further described in the EAA report.

Time Boundary	--- BOUNDARIES VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- The data derived from an industry survey from 1998 and includes literature data from reports dated 1998 and 1999.
Geographical Boundary	--- BOUNDARIES VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- It is not always explicit in the report where the different included process steps take place. Data may be acquired from outside of Europe, e.g. regarding ancillary processes. See litterature references (LitteratureRef) next to the flow table (FlowMetaData) for further information about the data sources for each process step.
Other Boundaries	See Nature boundaries for a specification of the cut-off criteria that has been applied.
Allocations	Allocations are not explicitly specified in the Environmental Profile Report 2000.
Systems Expansions	System expansions are not explicitly specified in the Environmental Profile Report 2000.

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, unspecified
Represents	Not relevant.
Method	PRODUCTION OF SEMI-FINISHED ALUMINIUM The data derive from an industry survey with a coverage ranging from 20% to 70%, depending on the product in question. INGOT REMELTING AND CASTING (RECYCLING OF PROCESS SCRAP) Data were obtained from aluminium-integrated cast house operations, i.e. cast houses associated with semi-finished aluminium production. The 1998 survey on semi-finished aluminium products also encompassed aluminium-integrated cast houses, with 37% coverage for the recycling of process scrap. TRANSPORTS Transport energy and air emission data have been taken from SAEFL Environmental Series 250 (1998) ''BUWAL 250'', table 16.9 ELECTRICITY For all manufacturing operations, the consumption of fossil fuels and emissions linked to electricity production was calculated according to the UCTPE 94 electrical energy model as described in BUWAL 250. Emissions from combustion only, i.e. without the precombustion contribution, have been considered where appropriate in order to make a direct comparision with the corresponding process emissions. Emission data for combustion came from a report prepared by EMPA for EEA (13 December 1997), showing the respective contributions of precombustion and combustion in 'BUWAL 250, table 16.9'. Although emissions from fuel combustion were often covered in the industry survey reporting, data calculated from BUWAL 250 were always used, inview of the fact that the survey results were not sufficiently reliable due to inconsistent use of conversion factors.
Literature Reference	---Aluminium foil production and process scrap recycling Industry survey from 1998 ---Transport energy, electricity, and air emission - SAEFL Environmental Series 250 (1998) ''BUWAL 250'', table 16.9 - EMPA report for EAA dated 27 April 1998, derived from Buwal 250 for national grid systems.
Notes	Includes electricity produced by nuclear and hydro power (hydro 263 kWh and nuclear 647 kWh). In this inventory profile it is possible to identify which process step (Aluminium foil production, Process scrap recycling) the flow is connected to, see Note-field for each specific flow. However, in order to get the numerical data devided on these two process steps, see Environmental Profile Report (EAA, 2000).

About Inventory

Publication	Environmental Profile Report for the European Aluminium Industry, European Aluminium Association, April 2000 -- Data documented by: Maria Erixon, IMI, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, IMI, Chalmers University of Technology Published in SPINE@CPM: 8 May 2002 --
Intended User	LCA-practitioners.
General Purpose	The European Aluminium Association (EAA) aims to contribute to further environmental improvements in aluminium products in a life cycle concept.
Detailed Purpose	The purpose with the Environmental Profile Report 2000 is to provide LCA-practitioners with detailed and up-to-date information representing the aluminium industry activities in Europe. The purposes with formatting the Environmental Profile Report 2000 for the European Aluminium Industry to the data documentation format SPINE, according to the data documentation criteria applied at Centre for environmental assessment of Product and Material systems (CPM) are: - CPM and European Aluminium Association (EAA) are anxious to provide life cycle assessment (LCA) practitioners with accurate and up to date environmental data for aluminium production. - EAA is interested in the SPINE formatting procedure and result, as the format is a base for (and therefor somewhat similar to) the new Technical Specification in ISO, ISO 14048, regarding LCA data documentation format. - EAA is interested in the CPM data quality control and documentation criteria.
Commissioner	- EAA (European Aluminium Association) 12 Av. de Broqueville B-1150 Brussels .
Practitioner	- EAA (European Aluminium Association) 12 Av. de Broqueville B-1150 Brussels .
Reviewer	Dr. Ian Boustead, - 2 Black Cottages West Grinstead, Horsham GB-West Sussex RH13 7BD
Applicability	--- SPECIFIC INFORMATION FOR THIS DATA SET --- ENERGY USE IN THE DIFFERENT INCLUDED PROCESS STEPS The energy directly consumed by the operations enclosed within the system bounderies, i.e. in the various production steps, are presented below. See the headline ''DATA SOURCES FOR FUELS/ENERGY PRODUCTION AND COMBUSTION'' in About Data for further information. Aluminium foil production--- Fuel oil (kg) 5,2 Gas (kg) 75 Electricity UCTPE* (kWh) 1475 ---Process scrap recycling--- Fuel oil (kg) 0,7 Gas (kg) 57 Electricity UCTPE* (kWh) 130 * UCTPE 94 is an electrical energy model for energy supporting all processes in this system (including transports), except electrolysis and cast house. It is described in BUWAL 250, see litterature references. --- GENERAL INFORMATION VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 ---

		RECOMMENDATIONS BY EAA WHEN USING THE DATA The data provided by the EAA members for their own process steps are the most up-to-date average data available for these processes, and it is recommended that they be used for LCA purposes. Older literature data should be disregarded, as it may no longer be representative due to technological improvements, progress in operating performance, changes with regard to raw materials or waste treatment, etc. To complete the product system inventory, data - on the production of consumer products, from semi-fabricated aluminium, - on the performance of consumer products in the use phase, and - on the recovery of scrap prior to remelting at the end of the product's useful life should be acquired. EAA recommend that these data be used in LCA studies in accordance with methodologies within the framework of the international standards in the ISO 14040-series. RELATED DATA SETS IN SPINE DATA FORMAT The data presented in the Environmental Profile Report is reformatted in to the SPINE format and structured according to the SPINE concept in as many separate activities (sub-systems) as possible. The system scope for the study as a whole is primary aluminium production, semi-finished aluminium production, and recycling. The SPINE formatting resulted in 7 activities. These activities are all published in the SPINE@CPM database. The production and recycling step are intended to be used together. For example, to obtain a cradle to gate-system for rolled aluminium sheet, the activity Primary aluminium production should be connected to the activity Production of rolled aluminium sheet. A recycling step (Aluminium recycling by refiners) could also be connected to such a system, depending on the scope. -- List of activities formatted in the SPINE-format, published in SPINE@CPM -- Primary aluminium production 1. Primary aluminium production Semi-finished aluminium product fabrication 2. Production of rolled aluminium sheet 3. Production of extruded aluminium profiles 4. Production of 0,02-0,2 mm single-rolled aluminium foil 5. Production of 0,005-0,02 mm double-rolled aluminium foil Recycling 6. Re-melting of aluminium scrap 7. Aluminium recycling by refiners Please note: The recycling process 6. Re-melting of aluminium scrap is included in the semi-finished aluminium product fabrication, i.e. activities 2-5. When designing a product system with the activities above where recycled aluminium is regarded, the activity Aluminium recycling by refiners should be used. The Re-melting of aluminium activity is only a specification if the user is specifically interested in this process step. RECYCLING RATES FOR ALUMINIUM PRODUCTS AFTER USE After use, aluminium products are a valuable re-usable resource. The European recycling rates for end products are currently around 95% for the automotive sector and 85% for the building sector. IMPROVEMENTS IN THE ENVIRONMENTAL PERFORMANCE OF ALUMINIUM PRODUCTS AND PROCESSES OVER THE PAST FEW YEARS Over the past few years EAA has achieved major improvements in the environmental performance of its production processes by means of the following: - improvement on existing technology - development and introduction of new technology and operations - increased recycling of all materials in the production process. Examples of major environmental improvements in aluminium products achieved over the past few years include: - weight reduction by downgauging in the packaging sector - energy savings through weight reduction and subsequent fuel reduction in the transport sector - reduction of maintenance in the building sector The previous Ecological Profile Report from EAA was published in 1996.
	About Data	--- GENERAL INFORMATION VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- PRECISION According to EAA, the environmental data figures in the inventory table are usually accurate to a precision of 5%. DATA SOURCES FOR FUELS/ENERGY PRODUCTION AND COMBUSTION

	The electricity supply systems and fuel production and use (transport energy and emission data) have been taken from SAEFL Environmental Series 250 (1998) 'Buwal 250' and EMPA report for EAA dated 27 April 1998, derived from Buwal 250 for national grid systems. All emissions connected with total fuel consumption (i.e. production and combustion of oil, gas or coal) have been taken from SAEFL Environmental Series 250 (1998) 'Buwal 250', table 16.9. Emissions from combustion only, i.e. excluding the contribution of the production of the fuel, have been considered where appropriate in order to make a direct comparision with the corresponding process emissions. Emission data for combustion came from a report prepared by EMPA for EEA (13 December 1997), showing the respective contributions of production and combustion of fuels in 'BUWAL 250, table 16.9'. Although emissions from fuel combustion were often covered in the industry survey reporting, data calculated from BUWAL 250 were always used, in view of the fact that the survey results were not sufficiently reliable due to inconsistent use of conversion factors. REVIEW OUTSPOKE Ian Boustead has reviewed and commented on the Environmental Profile Report for the European Aluminium Industry, April 2000, which is a revision of the first Ecological Profile Report from EAA that were published in 1996. Ian Bousteds' review comments on the Environmental Profile Report for the European Aluminium Industry, April 2000: ''...I have received the detailed calculations on which this present environmental report is based. All of the queries that I raised after working through these reports were answered satisfactory.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000 ''Good-quality data were supplied by the EAA member companies, and the number of companies participating provides good coverage of the various processes, meaning that the results can be regarded as representative of the industryas a whole for the production of primary aluminium and subsequent conversion processes.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000 ''Because of the very fragmented nature of the recycling industry and wide variations in practices, it is recognised that the data presented for this sector of the industry can only be regarded as indicative. Nevertheless it is helpful to have such information from an authorative source.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000
Notes	REVIEWER Ian Boustead has reviewed and commented on the Environmental Profile Report for the European Aluminium Industry, which is a revision of the first Ecological Profile Report from EAA that were published in 1996. See AboutData for review comments.

SPINE LCI dataset: Production of a Corrugated Board Box (182*62*182)

Administrative	
Finished	Y
Date Completed	2000-01-18
Copyright	FEFCO, Groupement Ondulé, KRAFT Institute
Availability	The database is available from KRAFT Institute without cost.

Technical System	
Name	Production of a Corrugated Board Box (182*62*182)
Functional Unit	One corrugated board box (182*62*182) mm
Functional Unit Explanation	The box is made of two layers of kraftliner and one layer of semichemical fluting.
Process Type	Gate to gate
Site	European average
Sector	Materials and components
Owner	European average

Technical system description	Corrugated board is composed of layers of paper: liner (linerboard) and fluting (corrugating medium) The four major paper grades used for the production of corrugated board boxes are Kraftliner, Testliner, Semichemical Fluting and Wellenstoff. The composition of the corrugated box depends of the function that it has to fulfil. Only the processes within the mill are included. That is, no transports to or from the mill are included. The forestry processes or paperproduction are included. Corrugated board is manufactured on a corrugator which consists of several steps running in line. In the process five steps are distinguished: 1. Shaping of the corrugated medium into continuous rolling waves (the flutes) and gluing the first linerboard facing. 2. Gluing one or more web of single faces and facings forming corrugeted board. 3. Creasing and cutting of the corrugated board web in the machine direction. 4. Cutting of the corrugated board web in the cross-machine direction. 5. Stacking of the corrugated sheets before finishing. The corrugated sheets are die-cut into box blanks i.e. any pre-cut section of corrugated board to be formed into a set-up box or portion of a box. The box itself is then ready for use.

System Boundaries

Nature Boundary	Emissions from fuel combustion outside the mill is not included in the data. Emissions to air from the sites have been reported. Emissions from incineration of rejects with energy recovery at the mill are included. Emissions in the steam of the paper mill are not included. Emissions to air originating from the use of biogas from the mills anaerobic wastewater treatment are included. Water that is taken in has to be treated before it is used in the process, and it is again treated after the process before it is released as effluent to a recipient. The substances in the effluent after wastewater treatment are reported.
Time Boundary	Thsi dataset is based on data from ''European Database for Corrugated Board-Life Cycle Studies'' where the data are from 1996. There will come an update on the database in the year 2000 where the data will be based on 1999.
Geographical Boundary	The data are average, based on 42 production plants, for production in Europe.
Other Boundaries	No transports to or from the mill are included. The forestry processes or the production of kraftliner and semichemical fluting are not included.
Allocations	Allocations have been made according to weight and proportions for the manufacturing of corrugated board boxes.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1996-01-01
Data Type	Derived, statistics
Represents	European average
Method	Data are all taken from the Eropean Database for Corrugated Board-Life Cycle Studies
Literature Reference	Eropean Database for Corrugated Board-Life Cycle Studies
Notes	Includes electricity produced by nuclear and hydro power (hydro 263 kWh and nuclear 647 kWh). In this inventory profile it is possible to identify which process step (Aluminium foil production, Process scrap recycling) the flow is connected to, see Note-field for each specific flow. However, in order to get the numerical data devided on these two process steps, see Environmental Profile Report (EAA, 2000).

About Inventory

Publication	The data are calculated from ''Eropean Database for Corrugated Board-Life Cycle Studies'' which is a public report published by FEFCO, Groupement Ondulé and KRAFT Institute. -- Data documented by: Åsa Ekdahl, M Sc. student at the dept. of Environmental Systems Analysis, Chalmers University of Technology and SKF Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 5 September 2001 --
Intended User	The intended users are LCA-pra
General Purpose	The purpose is to provide the industry and its customers the up-to-date knowledge, based on facts concerning the impact of the industry on the environment. Through this database the industry aims to make a contribution to the increasing need for basic environmental data for LCA studies, available in a transparent way. However, these data have been calculated for a box with the dimensions (182*62*182) mm.
Detailed Purpose	This data set has been documented specially for use in the study: ''LCA on SKF's Spherical Roller Bearing 24024''. The aim of the study is to descibe the environmental properties of the bearing as well as identify the processes contributing most to the environmental impact. It has also been calculated for a box with the dimensions (182*62*182) mm used for the specific bearing.
Commissioner	KRAFT Istitute - Norrtullsgatan 43 S-113 45 Stockholm .
Practitioner	Manufacurers of Corrugated Board in Europe - .
Reviewer	
Applicability	The data are applicable only to this specific box dimensions and composition of materials. Data for the production of Kraftliner and Semichemical fluting from the ''European Database for Corrugated Board-Life Cycle Studies'', that can be used together with this activity, is available in SPINE@CPM. These activites are named: - Production of Kraftliner - Production of Semichemical Fluting

About Data	
Notes	

SPINE LCI dataset: Production of Alkyl Polyglucosides (APG) from coconut oil

Administrative	
Finished	Y
Date Completed	95-01-01
Copyright	Carl Hanser Verlag
Availability	Public

Technical System	
Name	Production of Alkyl Polyglucosides (APG) from coconut oil
Functional Unit	1000 kg
Functional Unit Explanation	All emissions, use of resources and energy consumption is based on 1000 kg of APG.
Process Type	Cradle to gate
Site	Europe
Sector	
Owner	Europe
Technical system description	BRIEF DESCRIPTION: The following steps are involved in the production of APG: Coconut oil production: Process data for the production of coconut oil relate to the procurement and processing Philippine coconut oils. The country represents a major exporting country for this type of oil. Corn production: The process involves spreading of fertilisers and harvesting. Nitrogen fertiliser production: Nitrogen fertiliser is used for the corn production (cultivation of corn). Nitrogen is applied in the form of ammonia, which is manufactured by steam reforming of natural gas. Phosphorous fertiliser production: Phosphor fertiliser is used for the corn production (cultivation of corn). Phospate is applied as P2O5, which is produced by the action of sulphuric acid on phosphate rock. Potassium fertiliser production: Potassium fertiliser is used for the corn production (cultivation of corn). Potassium is generally applied in the form of KCl. The production process includes sylvite mining and processing, KCl production and potassium fertiliser production. Lime/lime stone production: Limestone is used for the corn production and is quarried from open pits. The process involved blasting, crushing screening and finally calcination of the limestone into lime. Sulphur production: No details were given om sulphur production. Glucose monohydrate production: Glucose monohydrate is produced from corn and sulphur. The process involves cleaning, wet milling, light milling, thourough milling, enzyme/enzyme hydrolysis and crystallisation. Salt production: Salt is used in the APG production process. No details were given on salt production. Caustic soda production: Caustic soda is used in the APG production process. No details were given on caustic soda production.

	APG production: APG is derived from fatty alcohols and glucose monohydrate by the Fischer Synthesis. Salt and caustic soda is also used in the process. Information concerning all the subsystems described above: Transports are included in the system. The fuels for the transports and the fuels for the processes are traced back to the extraction of petrochemical raw materials and/or extraction of bio fuels. The electricity data are based on the electricity profile for each country and the petrochemical and biomass raw materials for electricity production are traced back to the extraction process (same process as for fuel raw materials).

System Boundaries

Nature Boundary	All emissions are considered equivalent, independent of where they take place (locally, regionally, globally; in densely populated areas or rural areas).
Time Boundary	The process data used pertain mainly to 1992, being yearly averages where possible. It is recognised that operating processes and conditions are constantly evolving.
Geographical Boundary	This study examined the surfactant production in Europe, notably manufacturing processes conducted in Belgium, France, Germany, Italy, the Netherlands, Spain and the United Kingdom. Raw materials may be produced outside of Europe. Therefore, relevant input data from Malaysia, the Philippines and the United States of America have also been incorporated.
Other Boundaries	The detergent formulation, use and final disposal of the surfactants were not covered. The environmental effects associated with the manufacture of capital equipment and with energy and fuel requirements for plant and building conditioning (heat, air etc.) were not included, neither were those associated with personnel requirements. For electricity based on nuclear power and wind power, no emissions and resource exploits have been accounted for.
Allocations	Raw materials, energy and environmental emissions are allocated among co-products on an output weight basis, i.e. on the basis of mass. Co-products in this LCI include those materials that are currently recycled, reused or marketed in some beneficial way.
Systems Expansions	N/A (unless aggregated system from special type of comparative LCI study).

Flow Data

General Activity QMetaData

Date Conceived	1992
Data Type	Derived, unspecified
Represents	European average
Method	LC-inventory data from tables 1 and 3-5, pages 196-197 in lit.ref.
Literature Reference	Tenside Surfactants Detergents; 32. Jahrgang 2/1995; Carl Hanser Verlag; Munchen
Notes	The raw material data are given in ''kg'' and the energy data are given in ''MJ''. However, it is important to remember that the raw materials themselves have an energy content.

	Technology --
Intended User	Manufacturers and users of sur
General Purpose	-To produce an authoritative and comprehensive Life Cycle Inventory for major surfactant production in Europe through a common approach in order to facilitate objectivity in surfactant assessments on environmental grounds. -To secure the best possible validation of data and broad acceptance of the methodology and conclusions by industry, regulatory authorities, and academia, through assessment of the study by an appropriate expert review panel.
Detailed Purpose	-To establish an industry-wide inventory of the energy and emissions associated with the production of major surfactants in Western Europe under the conditions prevailing in 1992. -To bring together environmental data on the use of the main raw material sources - crude oil, natural gas, mineral, oleochemical, agricultural feedstock - for the processing pathways to the derived major surfactants. -To provide benchmarks for the processing steps of surfactant production against which individual producers can assess their own processes and identify opportunities for improvement. -To publish the results of the study and its conclusions in the open literature for access and reference by interested bodies.
Commissioner	- European LCI Surfactant Study Group (CEFIC/ECOSOL).
Practitioner	- Franklin Associates, Ltd. 4121 W. 83rd St., Suite 108 Prairie Village, KS 66208, USA.
Reviewer	Klöppfer, Prof. Dr. W. - C.A.U. Consultants Frankfurt, Germany
Applicability	It is generally not possible to replace one surfactant type by another without changing other components of a preparation, or altering performance characteristics. Therefore, it is not in general meaningful to compare surfactants on a weight basis. APGs comprise a comparatively new class of commercial surfactants. APGs show interesting synergy with other surfactants, which can enable the reduction of acrive ingredients at the same perfromance level. Besides their application in detergents they are well-suited to several cosmetic formulations and other surfactant applications, where special foaming abilities are required.
About Data	13 industrial companies participated in the project, including major surfactant manufacturers, raw material and intermediate suppliers, as well as surfactant users in Europe, some of whom are both manufacturers and users. Participating companies are BASF, Colgate-Palmolive, Condea, Enichem Augusta, Henkel, Hoechst, Hüls, ICI, Petresa, Procter & Gamble, Shell, Unilever and Wibarco. Process data were obtained directly from each company performing the process. These data were often proprietary. Therefore, technical process data from private corporations were collected from a minimum of three producers for each intermediate and surfactant type. The information is presented in the form of industry averages in order to preserve confidentiality. Fuel-related data for European countries were based on various governmental statistics and industry contacts (aggregated and provided by Dr. I. Bousted, The Open University, U.K.).
Notes	Data for other surfactants such as Alcohol sulphates (AS), Alcohol ethoxy sulphates (AES), soap, Secondary alkane sulphonates (SAS), Alcohol ethoxylates (AE) and Linear alkylbenzene sulphonates (LAS) were given in the same study.

Owner	
Technical system description	Exactly what techniques the data represent in this dataset is uncertain as the data are average data from literature. No specific production site has been studied. The text below only gives generic information about production of ammonia. Further information on interpretations of what the data represent is given under ''method'' in the flow data window. In theory, the synthesis of ammonia based on a methane feedstock, is (BAT N° 1, 1995): 1) 0.88 CH_4 + 1.24 H_2O ® 0.88 CO_2 +3 H_2 2) 3 H_2 + N_2 (from air) ® 2 NH_3 In industrial ammonia production the process may be subdivided into the following sections: a) Synthesis gas preparation 1) Gas production 2) Carbon monoxide conversion 3) Gas purification b) Compression c) Synthesis of ammonia The goal of synthesis gas preparation is to produce a gas mixture of nitrogen and hydrogen as pure as possible in the stoichiometric ratio of 1:3 (Ullman, vol. A 2, 1985). This can be done with different techniques. Currently in operation in Europe, the main types of production process for synthesis gas preparation are: a) Steam reforming of natural gas or other light hydrocarbons (liquidified natural gas, liquidified petroleum gas, naphtha) b) Partial oxidation of heavy fuel oil or vacuum residue Overall, gasification of hydrocarbons or coal can be seen as a partial oxidation at elevated temperatures. The main products are hydrogen and carbon monoxide. The necessary oxygen can be supplied either as steam, as oxygen or as air. If a catalyst is used and steam is the primary gasification medium, then the process is called steam reforming. If the reactant is oxygen or air and no catalysts are used, the process is called partial oxidation (Ullman, vol. A 2, 1985). About 85 % of world ammonia production is based on steam reforming concepts. Comparing natural gas reforming, heavy oil and coal gasification gives the approximate relative energy consumption figures of 1:1,3:1,7. Based on the known resources of fossil fuel, it is likely that natural gas will predominate as feedstock for the production of ammonia for the next 50 years at least. Today, about 77 % of world ammonia production is based on natural gas. In a long-term perspective, 50 to 100 years from now, coal may take over as feedstock, based on world reserves and consumption rate. Heavy oil may be attractive under special economical concerns, when natural gas is no longer available and the partial oxidation process could solve a waste problem (e.g. heavy residues and recycled plastics) (BAT N° 1, 1995) Three reforming techniques and one partial oxidation technique (of heavy residues) will be described briefly. Conventional steam reforming will be described more in detail and only deviations and additions will be stated for the other processes. Conventional Steam Reforming Desulphurization Most of the catalysts involved in the ammonia production process are sensitive to sulphur and sulphur compounds. The first step is therefore to desulphurize the feedstock. The feed gas is preheated to 350-400°C and is then treated in a desulphurization vessel. The sulphur that is not already in the form of hydrogen sulphide (H_2S) is hydrogenated to hydrogen sulphide, typically using a cobalt molybdenum catalyst. The hydrogen sulphide is then adsorbed on pelleted zinc oxide: 1) R-SH + H_2 ® H_2S + RH 2) H_2S + ZnO ® ZnS + H_2O By this reaction, the sulphur is removed to less than 0.1 ppm S in the gas feed. The hydrogen consumed in the reaction is usually recycled from the ammonia synthesis section. Primary Reformer The gas from the desulphurizer is preheated with steam to 500-600°C before entering the primary reformer. The process steam comes from an extraction turbine. In some plants a prereformer is used, in that case the gas steam mixture is reheated again in the section between the prereformer and primary reformer.

The primary reformer consists of a large number of high-nickel chromium alloy tubes filled with nickel-containing reforming catalysts. The reaction taking place is as follows:

a) $CH_4 + H_2O$ ® $CO + 3 H_2$
b) $CO + H_2O$ ® $CO_2 + H_2$

The first reaction is highly endothermic and additional heat is required to raise the temperature at the reformer outlet. The heat is supplied from burning of natural gas or other gaseous fuel, in the burners of a radiant box containing the tubes where the reactions take place. The flue-gas from the combustion of this fuel is the main source of emissions from the plant, consisting of carbon dioxide (CO_2), nitrogen oxides (NO_X) and small amounts of sulphur dioxide (SO_2) and carbon monoxide (CO) (BAT N° 1, 1995). Large amounts of carbon dioxide can also be released at the carbon dioxide removal stage if it is not used as feedstock in the production of urea.

Secondary Reformer
In the secondary reformer the remains of hydrocarbon are converted. To do this the temperature must be raised to increase the conversion. This is done by combustion of part of the gas with air. The air not only provides oxygen for the combustion but also nitrogen for the final synthesis of ammonia that takes place further on in the process chain. The process gas is mixed with air in a burner and then passed on over a second nickel-containing reformer catalyst.

Conversion of Carbon Monoxide
After the secondary reformer up to 99 % of the hydrocarbon feed is converted but there is still a 12-15 % content of carbon monoxide left. After cooling the carbon monoxide is therefore converted into carbon dioxide by using iron oxide/chromium oxide catalysts at high temperature and then copper oxide/zinc oxide-based catalysts at low temperature. This carbon monoxide conversion reduces the carbon monoxide content to about 0.2-0.4 %. A low residual carbon monoxide content is important for the efficiency of the process (BAT N° 1, 1995).

Carbon Dioxide Removal
The process gas now contains mainly hydrogen (H_2), nitrogen (N_2), carbon dioxide (CO_2) and excess process steam. Before ammonia can be synthesised carbon dioxide has to be removed. This is done in a chemical or a physical absorption process. The typical range of heat consumption in the modern chemical absorption process is 30-60 MJ/kmol CO_2. The physical absorption process may be designed for zero heat consumption but the mechanical requirements also have to be considered. Before entering the carbon dioxide removal system the process gas is cooled and the heat released during cooling is in many cases used for other heat demanding processes (BAT N° 1, 1995).

Methanation
As the ammonia synthesis catalysts are sensitive to carbon monoxide and carbon dioxide, these have to be removed completely by conversion to methane. With a nickel containing catalysts the following reactions take place at around 300°C:

$CO + 3 H_2$ ® $CH_4 + H_2O$
$CO_2 + 4 H_2$ ® $CH_4 + 2H_2O$

Methane will not react in the synthesis of ammonia, but water must be removed before entering the reaction chamber. Also, the synthesis gas is compressed before the final process stage (BAT N° 1, 1995).

Synthesis of Ammonia
The synthesis of ammonia takes place on an iron catalyst at around 100-250bar and 350-550°C:

$N_2 + 3H_2$ « $2 NH_3$

The reaction is exothermic and produced ammonia is separated by cooling. The equilibrium conditions of the reaction are quite unfavourable resulting in a poor conversion factor of only 20-30 % per pass. Loop pressure is maintained by substituting the ammonia that has been lead off with fresh synthesis gas.

The produced ammonia contains inerts (methane and argon). The level of inerts is kept low by taking out a purge stream from the loop. The purge stream is scrubbed with water to remove ammonia and is then used as fuel or sent to the desulphurization section where hydrogen is recovered.

Steam Reforming with Excess Air Secondary Reforming
The main difference from conventional steam reforming, is that in steam reforming with excess air in the secondary reformer the process is designed for reduced primary reforming by moving some of the duty to the secondary reformer. This is due to the low efficiency of the primary reformer. Reducing the primary reforming is done by decreasing the heat supply and thus the extent of reforming is reduced according to lower heat supply and lower temperature.

By increasing the internal firing by supplying more process air in the secondary reformer the same degree of total reforming as in conventional reforming is achieved. The process air requirement is about 50 % higher than in conventional reforming, this means increased compression capacity and energy demand. Usually, the process air compressor is driven by a gas turbine with the exhaust gas from the turbine being used as combustion air in the primary reformer (BAT N° 1, 1995).

	Before the synthesis gas enters the final stage of ammonia synthesis it passes a cryogenic purifier where all methane and excess nitrogen are removed. The cooling is produced by depressurisation and therefore no external cooling device is needed. By removal of essentially all impurities from the synthesis gas, a higher conversion per pass and a lower purge flow can be achieved in the ammonia synthesis. Heat Exchange Autothermal Reforming In this process the high-level heat from the secondary reformer outlet and the flue-gas from the primary reformer are recycled to the process itself. This is from a thermodynamic point of view better than to use the heat to raise steam as is done in conventional reforming. By using the heat in the gas from the secondary reformer in a newly developed primary reformer (heat exchange reformer), the fired furnace for heating of the primary reformer is eliminated. This reduces the emissions from the plant significantly as the flue-gas from the primary reformer is eliminated. Extra air or oxygen-enriched air is required in the secondary reformer for this autothermal process. Only two processes of this kind are presently in operation in Europe (BAT N° 1, 1995). Partial Oxidation of Heavy Oil The partial oxidation process is non-catalytic and takes place at high pressure (>50 bar) and high temperature (around 1400°C). Besides hydrogen, the formed gas also contains carbon dioxide, carbon monoxide, methane and some soot. The sulphur compounds in the feed are converted to hydrogen sulphide and then separated in a selective absorption step and reprocessed to elemental sulphur in a Claus unit (BAT N° 1, 1995). After conversion of carbon monoxide into carbon dioxide, the carbon dioxide is removed by using an absorption agent. The synthesis gas is then purified in a liquid nitrogen wash. In this unit practically all impurities are removed and nitrogen is added to give the stoichiometric ratio of hydrogen and nitrogen. The ammonia synthesis is quite similar to the one in conventional steam reforming, but simpler and more efficient. This is due to the high purity of the synthesis gas, therefore there is no need to take out a purge flow (BAT N° 1, 1995). Environmental Aspects The most important environmental impact owing to ammonia production is a large consumption of fossil fuel and emissions of fossil carbon dioxide (CO_2) as a consequence. There are also emissions of nitrogen oxides (NO_x), carbon monoxide (CO) and sulphur dioxide (SO_2). The latter is highly dependent on the type of fuel that has been used (BAT N° 1, 1995). In addition, there may be considerable leakage of natural gas (consisting mainly of methane, CH_4) due to the transport of natural gas in pipelines (Karlsson M pers. comm., 1998). System Boundaries	
Nature Boundary	The system starts with input of electricity, natural gas, crude oil and coal and ends with ammonia leaving the factory gate. Emissions and use of resources for production of electricity and emissions from extraction and combustion of energy resources are not included in this datset.
Time Boundary	The literature from which data are taken from are published in 1996 and 1998.
Geographical Boundary	Central and Eastern Europe.
Other Boundaries	
Allocations	Not applicable.
Systems Expansions	Not applicable.

Flow Data	
General Activity QMetaData	
Date Conceived	
Data Type	Derived, unspecified
Represents	European average
Method	According to Kongshaug (1998) 32.1 GJ/t NH_3 is the assumed average energy consumption for production of ammonia in Western Europe using the steam reforming process. About 41.2 GJ/t NH_3 is the assumed energy consumption for the most efficient plant 30 years ago and this gives a good indication of the energy consumption in a 30-year-old plant which has

	not been upgraded. The energy consumption for ammonia production using partial oxidation is 41-49 GJ/t NH3 (Kongshaug, 1998). The ammonia used in fertiliser production in Sweden is imported from Russia and Poland and it has been assumed that production techniques in these countries are comparable to the most efficient plants in Europe 30 years ago. This results in an energy consumption of 41.2 GJ/t NH3. When it comes to partitioning the energy consumption between the different energy sources natural gas, oil, coal and electricity, figures from Kongshaug (1998) and Patyk (1996), information on Hydro Agri's ammonia production in Europe and facts from EFMA have been taken into account. According to EFMA (Balken pers. comm., 1998) 0.20-0.29 GJ electricity/t NH3 is consumed when using the steam reforming process and 0.3 GJ/t NH 3 has therefore been chosen as representative for production in Central and Eastern Europe. According to Patyk (1996) there is a partition between the different energy sources natural gas, heavy oil and coal for production of ammonia used in Germany. This partition has been assessed to be representative for the rest of Western Europe when taking the other sources into account. This leads to the division of the energy consumption as follows: 31.6 GJ natural gas /t NH3, 5.33 GJ heavy oil/t NH3 and 3.94 GJ coal/t NH3.

About Inventory

Publication	Davis J, Haglund C (1999). ''Life Cycle Inventory (LCI) of Fertiliser Production - Fertiliser Products Used in Sweden and Western Europe''. SIK report no. 654. The Swedish Institute for Food and Biotechnology (SIK). Gothenburg, Sweden. -- Data documented by: Jennifer Davis, SIK (The Swedish Institute for Food and Biotechnology). Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The data are intended to be us
General Purpose	To generate an inventory of emissions and use of resources due to the production of fertilisers produced and used in Sweden.
Detailed Purpose	The purpose was not to compare the production of different fertilisers but to generate a thorough inventory of emissions and use of resources due to the production of different fertilisers used in Sweden. The data are intended to constitute a useful basis of input information in life cycle assessments of food production systems. The production of ammonia is one step in the line of production of fertilisers containg nitrogen.
Commissioner	- SIK AB, The Swedish Institute for Food and Biotechnology Box 5401 SE-402 29 Gothenburg Sweden .
Practitioner	Davis, Jennifer and Caroline Haglund - SIK AB Box 5401 402 29 Gothenburg Sweden.
Reviewer	-
Applicability	The dataset is applicable for production of ammonia in Central and Eastern Europe. It is included in the aggregated datasets for fertiliser production in Sweden (cradle to gate).
About Data	The data are gathered from reports and literature, i.e. information has not been taken from a specific site. The dataset is intended to be reresentative for production of ammonia that is used in fertiliser production in Sweden.
Notes	Internal review of the report was performed by: Olle Ramnäs, CTH (Chalmers University of Technology), Berit Mattsson and Magnus Stadig, SIK (The Swedish Institute for Food and Biotechnology).

SPINE LCI dataset: Production of ammonium nitrate

Administrative	
Finished	Y
Date Completed	1999-01-25
Copyright	
Availability	Public (confidential energy flow data are not included).

Technical System	
Name	Production of ammonium nitrate
Functional Unit	1 kg of ammonium nitrate (100 % ammonium nitrate)
Functional Unit Explanation	
Process Type	Gate to gate
Site	Hydro Agri AB Box 908 SE-731 29 Köping Sweden
Sector	Materials and components
Owner	Hydro Agri AB Box 908 SE-731 29 Köping Sweden
Technical system description	At the plant operated by Hydro Agri AB in Köping, ammonia and nitric acid are mixed in a reactor. The ammonium nitrate solution is then evaporated in three evaporators using the heat generated in the neutralisation of ammonia and nitric acid. The condensate from the first evaporator is partly recycled to the reactor. The pressure in the second and third evaporator is lower than in the first. The ammonium nitrate solution leaving the last evaporator has a concentration of 95 % ammonium nitrate. The steam from the evaporators is cleaned in a scrubber and further on used for district heating and heating of process water. References: Miljörapport Hydro Agri AB Köping (1998). Official environmental report. Hydro Agri AB, Box 908, 731 29 Köping. Personal communication: Karlsson L-H (1998). Hydro Agri AB, Köping. Tel. +46 (0)221 27800

System Boundaries	
Nature Boundary	The system starts at the incoming factory gate and ends at the outgoing factory gate, i.e emissions and use of resources due to the production of input materials and energy are not included in this dataset.
Time Boundary	The data are taken from production in 1997.
Geographical Boundary	The plant is situated in Köping, Sweden.
Other Boundaries	
Allocations	Energy consumption/production from the preceeding nitric acid production step is included in the energy figures. Emissions of nitrogen to water also include contribution from production of nitric acid.
Systems Expansions	Not applicable.

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	European average
Method	Amounts of ammonia and nitric acid consumed in the production of ammonium nitrate were calculated by using the molecular mass of nitric acid and ammonia respectively. A large fraction (97 %) of the nitric acid produced at the site is used for production of ammonium nitrate, which was calculated by subtracting the total amount of nitric acid consumed in the production of ammonium nitrate from the total amount of nitric acid produced at the site in 1997. Total amounts of emissions of nitrogen to water and consumption/production of energy due to the production of nitric acid and ammonium nitrate were divided by total amount of ammonium nitrate produced in 1997.

Applicability	The dataset is applicable for production of ammonium nitrate produced at Hydro Agri AB in Köping, Sweden. The ammonum nitrate is mixed with other components forming calcium ammonium nitrate (CAN) or NPK fertilisers.The dataset is included in aggregated datasets for fertiliser production at Hydro Agri AB in Köping (cradle to gate).

	Note that energy consumption/production in to the preceeding step of nitric acid production is included in this dataset.
About Data	Data are collected from the official environmental report distributed by Hydro Agri AB in Köping and also by contact with Lars-Håkan Karlsson and Bo Andersson, Hydro Agri AB in Köping. Energy flow data are confidential and are not included in this dataset.
Notes	Internal review of the report was performed by: Olle Ramnäs, CTH (Chalmers University of Technology), Berit Mattsson and Magnus Stadig, SIK (The Swedish Institute for Food and Biotechnology).

SPINE LCI dataset: Production of bearing rings

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Production of bearing rings
Functional Unit	One inner ring 232/530 IR and one outer ring 232/530 OR
Functional Unit Explanation	One spherical roller bearing 232/530 consists of following components: 1. one inner ring 2. one outer ring 3. one guide ring 4. one brass cage 5. 36 rollers (coated or non-coated) The functional unit for this process is one inner ring 232/530 IR (356 kg) and one outer ring 232/530 OR (387 kg). The data can be used (together with data for the other ingoing components) to calculate environmental impact for a complete spherical roller bearing 232/530. Dimensions of the bearing 232/530: di= 530 mm dy= 980 mm breadth= 355 mm The activities for the production of the other ingoing components are also available at SPINE@CPM: * Production of bearing rollers (á 9.2 kg) * Production of brass cages used for spherical roller bearings * Production of guide rings used for spherical roller bearings and the activity for the production of a complete SRB 232/530 can be found as: * Production of SKF Spherical Roller Bearing 232/530
Process Type	Cradle to gate
Site	SKF Sverige AB415 50 GÖTEBORG
Sector	Materials and components
Owner	SKF Sverige AB415 50 GÖTEBORG
Technical system description	The SKF spherical roller bearing 232/530 contains of an inner and an outer ring, 36 rollers, a guide ring and one brass cage. This data set describes the Production of bearing rings for the SKF spherical roller bearing 232/530. The following process steps are included in this dataset: 1. Production of clean bearing steel 2. Heating of ingot at the rolling mill 3. Forging of ingot into steel bars, 350 mm

4. Production of steel rings
5. Turning of steel rings at SKFs site in Göteborg
6. Heat treatment of bearing rings
7. Ring processes at SKFs site in Göteborg

1, 2, 3, 5 and 7 is documented and available in the SPINE@CPM database.

The mineral oil in the cutting fluid used at SKFs site in Göteborg is followed from the cradle with the activities:
8. Extraction of crude oil
9. Refining of crude oil
And to the grave with the activity:
10. Combustion of waste oil

The steel scrap from the ringprocesses at SKFs site in Göteborg is sent to Ovako Steel AB in Hofors for recycling.

All transports between the different sites are included and also the production of diesel, electricity, light fuel oil, LPG and heavy fuel oil.
The transports are:
A. Transport with truck from Hofors - Söderfors (ingot)
B. Transport with truck from Söderfors - Hofors (steel bars)
C. Train transport Hofors - Sävenäs (steel rings)
D. Train transport Sävenäs - Hofors (steel scrap for recycling)
E. Transport with truck Göteborg - Halmstad (cutting fluid)

1. Production of clean bearing steel:
Roller bearings must be produced from extremely clean steel that possesses maximum fatigue strength. SKF had realized this already by 1916 when they bought the Hofors Steel Mill, followed by the Hällefors Steel Mill in 1957. This cooperation with SKF has made the company now called Ovako Steel AB the world`s leading producer of bearing steel.
The steel produced at Ovako Steel AB in Hofors, Sweden, the raw material for the outer and inner rings, is completely produced from scrap. New data has been obtained for all process steps.

When the scrap arrives at Ovako Steel AB in Hofors it is sorted according to quality and alloy elements. The scrap is melted in an electric arc furnace where oxygen and carbon is added. The addition of oxygen and carbon makes the slag porous and in turn makes the process more effective. When the scrap is completely melted the slag is removed and the melt is poured into a ladle furnace where the steel is degassed and final adjustments of the alloys are made. The steel is then teemed uphill into ingot moulds. The moulds are finally removed.

2. Heating of ingot at the rolling mill:
At the rolling mill at Ovako Steel in Hofors the ingots are rolled into billets.
The ingots are first heated in a soaking pit to the proper rolling temperature. When the ingot has been rolled in the first stand of rolls it is transported to the oxygen-scarfing machine where surface defects are removed from the billet. The billet rolling is then continued in rolling stand 2 and 3. Depending on what will become of the ingot it is rolled to round or square billets. Finally the billets are inspected and surface defects, if any, are removed by grinding.

IN THIS SPECIFIC CASE THE INGOT IS ONLY HEATED IN THE SOAKING PIT AT THE ROLLING MILL. Instead of rolling in the rolling stands the ingot is transported to Scana Steel AB in Söderfors for forging into bars.

3. Forging of ingot into steel bars, 350 mm:
The ingot is after the rolling mill transported to Scana Steel AB in Söderfors for forging into bars, 350 mm, and then back to Ovako Steel AB in Hofors to the final treatment at the ring mill.
The ingot is cold when the process starts at the forge at Scana Steel AB in Söderfors. As a first step the ingot is heated in an oven. The first part of the oven heats the ingot from room temperature to 180°C immediately. The ingot is then transported through different temperature areas and is slowly heated until it reaches 1150°C. This heating process takes approximately 1-2 days.
The next process step is pressing in the forging press. The heated ingot is put in the press and edged into round shape. Finally the now nearly round bars are pressed complete round while rotating against a round swage in form of two half circles. The forging is completed and the forged bars are inspected and cooled in room temperature for approximately one day.
The forged bars are transported back to Ovako Steel AB in Hofors by truck.

4. Production of steel rings:
The production of the rings takes place at the ring mill (ring mill number 9) at Ovako Steel AB in Hofors, Sweden. The process steps for the inner and outer ring are completely the same, and therefore the process will be described only once.
The forged bars (blanks) from Scana Steel AB in Söderfors are cut cold in a Wagner sawing machine and heated in rotating hearth furnaces. The blanks are then upset and pierced in a press. The pierced blanks are subject to intermediate heating in a batch furnace before finish rolling in an axial/radial rolling mill. The rings are rolled to a certain profile specific to the demands of SKF.
After forging and rolling the rings have their final dimensions. The rings are heat treated to obtain the required material properties and the oxide scale formed during the treatment is then blasted off. The rings are packed and transported by train to SKF in Göteborg,

	Sweden. 5. Turning of steel rings at SKFs site in Göteborg: The rings from Ovako Steel AB are treated further at the SKF production plant in Göteborg. The ring processes at SKF can be divided into three main steps: 1. Soft treatment 2. Hardening 3. Hard treatment For large sized bearings more work is done by hand and a smaller quantity is produced. The soft treatment starts with turning for both rings. The rings are turned into their final shape. For the outer ring this also means that a channel with holes for lubrication is made. For the SRB 232/530 the turning process takes place at the C-factory in production channel 23 for both rings. After the turning both the rings are inspected by ultra sound. This is done for 100% of the rings of this dimension. The reason is to make sure that the material is solid and homogenous through the whole ring. If a crack would be discovered the whole ring will be scrapped. 6. Heat treatment of bearing rings After the ultra sound inspection the rings are hardened. The data set for the heat treatment of bearing rings is obtained from an earlier LCA study of medium-sized bearings by Åsa Ekdahl and can be found in SPINE@CPM database. In the hardening process the rings are heat treated to make the metal harder and tougher. The heat treatment proceeds through an oven with 9 different positions. The outer and inner rings are treated differently since the thickness of the rings differs. The processes as such are similar and the final material is for both rings bainite, but the temperatures and holding times to obtain the structure are different. First the rings are heated in the first part of the oven. The inner ring is heated to 885°C and the outer ring to 870°C. The function of the last part of the oven is to hold the temperature, during the specific time it takes for the material to get the right properties. The rings are then quenched in a salt bath to 210°C. The rings are kept in the salt bath for the time needed for the material to change. The temperature kept in the last salt bath is 235°C for both rings, but the holding time is longer for the inner ring. The salt bath is half sodium nitrite and half potassium nitrate kept in solution. The salt bath also gives the rings a protective layer of salt. 7. Ringprocesses at SKFs site in Göteborg The hard treatment begins with grinding. Both sides on both rings are ground because of the need of reference surfaces when inspected with ultra sound. Additional material is turned off and the scrap is sent back to Ovako Steel AB for recycling. After the turning the inner ring is polished and the outer ring is ground once again. This is the only difference between the two rings in the process at SKF. The jacket surface of the outer ring is spherically ground to be able to hold the rollers in place. In this step the outer ring also obtains its checked pattern on the inside, so that the lubricant can spread easily on the steel surface. The rings are now ready for assembling.

System Boundaries

Nature Boundary	For the process steps 1-4 both emissions to air and water are included. For the processes at SKFs site in Göteborg, emissions to air are not measured and could therefore not be reported in this study. The steel used for the rings are 100 % made from scrap and is not seen as a resource, but comes from the technosphere.. The steel scrap from the process at SKF, Göteborg is sent to Ovako Steel in Hofors for recycling and is therefore not seen as waste, but a co-product to the technosphere.
Time Boundary	The data was collected during the autumn 2002.
Geographical Boundary	The production of bearing steel, the hot rolling of ingot and the production of steel rings take place at Ovako Steel AB in Hofors, Sweden. The forging of ingot into steel bars, 350 mm, takes place at Scana Steel Söderfors AB in Söderfors, Sweden. The ringprocesses at SKF takes place in Göteborg, Sweden.
Other Boundaries	All production of electricity and other energy sources are included in this dataset. Average swedish electricity production has been used. In the activity ring processes at SKFs site in Göteborg, internal transport within SKF Industrial Area in Göteborg in included (1 km electric truck). BeTe Truck AB in Sweden has estimated the consumption of an electric truck: 0,75 kWh/km. The electricity production is included for all activities and is calculated as Swedish average electricity. The transports included are further described under ''function''. The production of electricity

	and diesel are included. The mineral oil in the cutting fluid (used at SKFs site in Göteborg) has been traced back to its cradle. The cutting fluid is an emulsion consisting of 4 % Castrol SW 3420. Castrol SW 3420 consists of 40% mineral oil according to the product data sheet (Castrol SW 3420). The amount of mineral oil has been accounted for. The activities ''Extraction of crude oil'' and ''Refining of crude oil'' have been used from SPINE@CPM. The mineral oil in the emulsion has also been traced to its grave. It is separated from the water content and burnt in Halmstad and used as energy source for the cement industry. The activity used is ''Combustion of waste''. It can also be found in SPINE@CPM database.
Allocations	Allocations have been made according to weight and production. For the activity 1-4 it is only allocated according to weight. For the process steps at SKFs site in Göteborg, energy consumption depends on how long the rings are processed in the different process equipment. This varies according to weight, but also according to size and desired properties of the final product. The cutting fluid used in the process is allocated according to weight.
Systems Expansions	Not applicable

About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Data reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The data is valild for production of bearing rings of the same material and weight, produced in the same way and at the same locations since the tranportation between the sites also are included in this dataset The data can be used (together with data for the other ingoing components) to calculate environmental impact for a complete spherical roller bearing 232/530. The activities for the production of the other ingoing components are also available at SPINE@CPM: * Production of bearing rollers (á 9.2 kg) * Production of brass cages used for spherical roller bearings * Production of guide rings used for spherical roller bearings and the activity for the production of a complete SRB 232/530 can be found as: * Production of SKF Spherical Roller Bearing 232/530
About Data	Data is gathered from interviews with Eva-Maria Arvidsson at Ovako Steel AB in Hofors, Sweden, Leif Hedström at Scana Steel AB in Söderfors, Sweden, Thomas Lundberg and Janne Bertilsson at SKF Large Bearings AB in Göteborg. Some data is obtained from existing databases (SPINE@CPM database) The energy and transport database from CIT Ekologik AB, 2002, has been used for average swedish electricity production data.
Notes	

SPINE LCI dataset: Production of bearing rollers (à 9,2 kg)

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Production of bearing rollers (à 9,2 kg)
Functional Unit	One bearing roller, 9.2 kg
Functional Unit Explanation	One spherical roller bearing 232/530 consists of following components: 1. one inner ring 2. one outer ring 3. one guide ring 4. one brass cage 5. 36 rollers (coated or non-coated) The functional unit for this process is ONE roller. The data can be used (together with data for the other ingoing components) to calculate environmental impact for a complete

	spherical roller bearing 232/530. The activities for the production of the other ingoing components are also available at SPINE@CPM: * Production of bearing rings * Production of brass cages used for spherical roller bearings * Production of guide rings used for spherical roller bearings and the activity for the production of a complete SRB 232/530 can be found as: * Production of SKF Spherical Roller Bearing 232/530 Dimensions of the bearing 232/530: di= 530 mm dy= 980 mm breadth= 355 mm
Process Type	Cradle to gate
Site	SKF Large Bearings
Sector	Materials and components
Owner	SKF Large Bearings
Technical system description	This activity describes production of bearing rollers (à 9,2 kg). 36 bearing rollers of this type are needed for one SKF spherical roller bearing 232/530. The bearing rollers are mounted into SKF spherical roller bearing 232/530. The bearing rollers are made from steel bars, 117 mm. The steel bars, produced at the Stockbridge Works in Sheffield by Corus Engineering Steels, are transported from Sheffield in England to Kode in Sweden for cutting and then finally to SKF in Göteborg for further processing into rollers. The following process steps are included in this dataset: 1. Cutting of steel bars (117 x 147 mm) 2. Turning of steel bars into bearing rollers 3. Transport E Factory - C Factory 4. Hardening of bearing rollers. 5. Transport C Factory - E Factory 6. Grinding of bearing rollers. 7. Handpolishing of bearing rollers. 8. Production of grinding paper. Process step 1,2,6 and 7 are documented according to SPINE and can be found in the SPINE@CPM database. The steel scrap is sent to Ovako Steel AB in Hofors, Sweden, for recycling. Also the train transport from Göteborg to Hofors are included in the dataset. As a first process step at SKF, the rollers are turned in the SMT lathe into desired shape. The steel scrap is sent to Ovako Steel AB, Hofors, for recycling. The rollers are then sent to the (hardening) heat treatment. The heat treatment is located in another factory within the SKF Gothenburg industrial area. The data set for the heat treatment is obtained from an earlier LCA study of medium-sized bearings performed by Åsa Ekdahl and is available at SPINE@CPM, LCI database: ''Heat treatment of bearing rings''. The only difference in the heat treatment for rings and rollers is that the rollers are hardened to martensite. This treatment does not demand as high temperatures and long holding times as for hardening to a bainitic structure. The rollers are heated to 845°C and are then quenched to 170°C in the salt bath. Another difference is that the rollers must be cooled very slowly to room temperature before they are tempered into the new structure at 220°C in the last salt bath. After the heat treatment the rollers are transported back to the E-factory and all sides of the rollers are ground and hand polished. The production of grinding paper is accounted for in this dataset and approximated with the activity ''Production of Kraftliner'' from SPINE@CPM database. The transport from Västervik (Slipnaxos AB) where the grinding paper is manufactured is NOT included. The last step before packing is inspection of material quality by ultra sound. Also the diameter of the rollers is inspected. A standard deviation of roller diameter of more than 5 mm is not allowed. The rollers for the non-coated bearing are now ready for assembling. The rollers for the coated bearings are sent to Halmstad for coating. For further infomation Round billets, 125 mm, are produced from the steel ingot at the rolling mill in Sheffield. No data was available for these activities, but they can be approximated with other similar datasets from SPINE@CPM database:. ''Production of clean bearing steel'' and '' Manufacturing of Hot Rolled square billets, 150 mm'' These activities are NOT included in this dataset.

System Boundaries	
Nature Boundary	Emissions to air are NOT measured for the process steps: * Cutting of steel bars (117x147 mm) * Turning of steel bars into bearing rollers * Grinding of bearing rollers * Handpolishing of bearing rollers and could therefore not be reported in this study. For all other steps the emissions to air are included. Emissions to water and the use of cutting fluid at SKF, Göteborg, could according to allocation difficulties and lack of time not be calculated. The steel used for the rollers are 100 % made from scrap and is not seen as a resource, but comes from the technosphere. The steel scrap from the process at SKF, Göteborg is sent to Ovako Steel in Hofors for recycling and is therefore not seen as waste, but a co-product to the technosphere.
Time Boundary	The data was collected during the autumn 2002.
Geographical Boundary	All processes take place in Sweden. The cutting of the steel bars takes place in Kode, Sweden, and the other process steps are site specific for SKF in Göteborg, Sweden.
Other Boundaries	Internal transport within SKF Industrial Area in Göteborg in included (2 km electric truck) BeTe Truck AB in Sweden has estimated the consumption of an electric truck: 0,75 kWh/km. For the cutting of steel bars (117x147 mm) internal transport with diesel truck is included (15 s). Assumptions were made at BeTe Trucks AB in Sweden how much energy a dieseltruck consume per hour (=6 litres/h (average value)). The heating value for diesel (=35, 31 MJ/litre) was found at Internet: www.fast-tech.com and the diesel consumption could be calculated to 0,88275 MJ/15 s. The diesel production is included in the dataset. The electricity production is included for all activities and is calculated as Swedish average Electricity. The production of grinding paper are approximated with production of Kraftliner (data obtained from SPINE@CPM database). The production of grinding paper takes place in Västervik, Sweden, but the transport from Göteborg to Västervik is not included in this dataset. The steel scrap from the process at SKF, Göteborg, is tranported by train to Ovako Steel in Hofors. This tranport is also included in the study.
Allocations	Allocations have been made according to weight and production. Energy consumption depends on how long the rollers is processed in the different process equipment. This varies according to weight, but also according to size and desired properties of the final product.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData	
Date Conceived	02-08-01 - 02-12-31
Data Type	Derived, mixed
Represents	European average
Method	Data is gathered from interviews with Niclas Thim, SKF Large Bearings, Sweden and with Lars Andersson, Corus Group Sweden AB. See under each sub activity for more detailed information.
Literature Reference	Miljörapport Hydro Agri AB Köping, (1998). Official environmental report. Hydro Agri AB, Box 908, 731 29 Köping. Personal communication: Andersson B (1998). About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Data reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The data is valild for bearing rollers of the same material and weight and with the same processing steps at the manufacturing. The data can be used (together with data for the other ingoing components) to calculate environmental impact for a complete spherical roller bearing 232/530. The activities for the production of the other ingoing components are also available at

	SPINE@CPM: * Production of bearing rings * Production of brass cages used for spherical roller bearings * Production of guide rings used for spherical roller bearings and the activity for the production of a complete SRB 232/530 can be found as: * Production of SKF Spherical Roller Bearing 232/530
About Data	Data is gathered from interviews with Niclas Thim, SKF Large Bearings, Sweden and with Lars Andersson, Corus Group Sweden AB. Data from the cutting process in Kode is obtained from the product manager in Kode and from Niclas Thim.
Notes	

SPINE LCI dataset: Production of Bearing Steel

Administrative	
Finished	Y
Date Completed	2000-01-17
Copyright	
Availability	Public

Technical System	
Name	Production of Bearing Steel
Functional Unit	one ton of produced bearing steel
Functional Unit Explanation	The bearing steel quality is SKF3, 100Cr6.
Process Type	Cradle to gate
Site	Steel Mill Ovako Steel AB 813 82 Hofors Sweden
Sector	Materials and components
Owner	Steel Mill Ovako Steel AB 813 82 Hofors Sweden
Technical system description	These are the process steps included in the data set: 1. Melting 2. Deslagging 3. Ladle Furnace Treatment 4. Degassing 5. Ingot Teeming 6. Stripping The bearing steel is produced completely from scrap which is melted in an electric arc furnace. The steel is teemed to ingots weighing 4200 kg each. The quality of the steel is SKF3, 100Cr6.

System Boundaries	
Nature Boundary	Emissions to air are considered. Emissions to soil are not considered. Emissions to water are not considered.
Time Boundary	The data are based on the production in 1998. The bricks used in the ladle furnace is from 1999 sent back to the producer for recycling. In 2000 the olivine is recycled.
Geographical Boundary	The Steel Mill is located in Hofors, Sweden.
Other Boundaries	Production of raw material is not included. Production of electricity is not included. Waste treatment is not included. Subsystems concearning employees are not included. Transports are not included.

Allocations	No allocations have been necessary. The data are simply divided by the total tons produced in 1998. This is because all the processes are the same no matter what steel type is produced.
Systems Expansions	not relevant

Flow Data

General Activity QMetaData

Date Conceived	1998-01-01
Data Type	Derived, unspecified
Represents	European average
Method	The data are from Ovako's purchase register and environmental report. It has been divided by the steel (in tons) produced in 1998.The data have not been allocated since all processes are used for every steel type.
Literature Reference	Ovako Steel internal information system
Notes	Energy flow data are confidential. Energy consumption/production from the preceeding nitric acid production step is included in these energy figures. Emissions of nitrogen to water also include contribution from production of nitric acid.

About Inventory

Publication	Master's thesis ''LCA on SKF's Spherical Roller Bearing 24024'' by Åsa Ekdahl, ESA-report 2001:1, Department of Environmental Systems Analysis (ESA), Chalmers University of Technology (ISSN 1400-9560) This report is available for download at ESAs web-site: http://www.esa.chalmers.se --- Data documented by: Åsa Ekdahl, M Sc. student at the dept. of Environmental Systems Analysis, Chalmers University of Technology and SKF Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 5 September 2001 ---
Intended User	The intended users of this dat
General Purpose	The general purpose for this data inventory is to document data in a way suitable for LCA studies.
Detailed Purpose	The data are to be used in the study: ''LCA on SKF's Spherical Roller Bearing 24024''. The aim of the study is to descibe the environmental properties of the bearing as well as identify the processes contributing most to the environmental impact.
Commissioner	Patrik Lindroth - SKF Sverige AB SRB Medium D3s3 415 50 Göteborg .
Practitioner	Ola Stuffe - Ovako Steel AB 813 82 Hofors Sweden .
Reviewer	
Applicability	The data are applicable to the production of bearing steel (SKF3, 100Cr6) at the Steel Mill at Ovako Steel in Hofors, Sweden.
About Data	
Notes	The data have been collected by Ola Stuffe at Ovako Steel under the supervision of Åsa Ekdahl.

SPINE LCI dataset: Production of beef. ESA-DBP

Administrative	
Finished	Y
Date Completed	2005
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Production of beef. ESA-DBP
Functional Unit	1 kg of beef
Functional Unit Explanation	
Process Type	Gate to gate
Site	Swedish Meats, Örebro, Sweden
Sector	Crop and animal production, hunting etc.
Owner	Swedish Meats, Örebro, Sweden
Technical system description	Excerpt from the report, see 'Publication': ''The Swedish meat consumption is quite constant, about 25 kg beef and 36 kg pork per capita each year. Domestic production accounts for 58% (139 million kg) and 79% (295 million kg) of the beef and pork production respectively. The company participating in the study, Swedish Meats, is one of the biggest food companies in Sweden, producing 58% of the slaughtered meat consumed. The company offers slaughtering and refining of beef, lamb and pork. The production of meat affects the environment in many ways. As for eutrofication and acidification, the largest contributor is the handling of manure; either in storage or as fertiliser in agriculture. Here ammonia in the form of emissions from manure and nitrogen leakage from crop cultivation are the most important substances, for acidification and eutrofication respectively. The cultivation of crop for use as fodder in the animal production affects the environment in other ways also, as an example the production of 1 kg of pork requires 11 m2 of land, out of which 9 m2 in Europe and 1.5 m2 in South America, the latter mainly for soy cultivation. A cow emits about 120-130 kg methane annually, which corresponds to the global warming potential of the carbon dioxide emissions from an average car driven 12 600 km. This methane is formed by micro organisms in the cow's stomach when fodder is broken down and most of this is released through the cow's mouth. This process is included in the system described in: Abelmann A. (2005). Environmental Potential of Increased Human Consumption of Grain Legumes. An LCA of food products. Master thesis. ESA report 2005:10, ISSN: 1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2005--10.pdf Other processes in the CPM Database also included in the above publication: - Sausage (Soy-Dog) production. ESA-DBP - Sausage (Pea-Dog) production. ESA-DBP - Sausage (Hot-Dog) production. ESA-DBP - Operation of 'Hot Dogs' producing facility. ESA-DBP - Pea cultivation. ESA-DBP - Production of pork. ESA-DBP - Rape seed cultivation. ESA-DBP - Wheat cultivation. ESA-DBP - Sugar beet cultivation. ESA-DBP - Soy bean processing. ESA-DBP - Soy bean cultivation. ESA-DBP

System Boundaries	
Nature Boundary	Data include use of energy, as well as emissions to the air and water.
Time Boundary	The data come from the report which was completed in 2002.
Geographical Boundary	Excerpt from the report, see 'Publication': ''Most ingredients in the two animal-based products originate from Sweden.

Other Boundaries	Excerpt from the report, see 'Publication': ''Not included are any aspects regarding personnel. (...) Some ingredients in the food processes have been judged to contribute very little to the overall process, and have therefore been excluded.''
Allocations	No information about the allocation in the report.
Systems Expansions	Not applicable

SPINE LCI dataset: Production of benzene (APME)

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Production of benzene (APME)
Functional Unit	1 kg benzene
Functional Unit Explanation	Typical uses for benzene is for styrene and ethyl benzene, cumene and phenol, cyclohexane, nitrobenzene and aniline, and detergent alkylate. Benzene can be extracted from pyrolysis gasoline through repeated distillation and directly from naphtha by a process known as catalytic reforming.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. Production of benzene include all major operations from extraction of crude oil and gas to catalytic reforming of naphtha, solvent extraction and fractional distillation. Most benzene is produced directly from naphtha by catalytic reforming, a process in which naphthenic compounds in naphtha are dehydrogenated. The basic feedstock is thus converted into a mixture of products, mainly benzene, toluene and xylene; hence, the process is often called the BTX process. Benzene and the other aromatics are isolated in the pure state form the output of the reformer by solvent extraction and fractional distillation. The output of benzene is maximised if the naphtha feed is rich in ring compounds containing 7 carbon atoms. In addition to the mentioned sub-processes, the following major processes are included: Crude oil extraction and delivery; oil refining for naphtha (fractional distillation); natural gas extraction, processing and deliver; coal mining and delivery. Also electricity production and production of other raw materials have been included on a cradle to gate basis, i.e. all materials and energies have been tracked back to the extraction of raw materials from the earth.

	Operating conditions: As the data are based on information from 14 plants in 6 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. Although benzene is usually present in small quantities in crude oil, its direct extraction is usually uneconomic. However, one by-product of naphta cracking is a liquid usually referred to as pyrolysis gasoline which is high in unsaturated aliphatic and aromatic hydrocarbons. The benzene fraction in pyrolysis gasoline can be extracted by repeated distillation and it is thought that about half of all benzene used in Europe is produced in this way. Benzene is also produced directly from naphtha by a process known as catalytic reforming. This process leaves the number of carbon atoms in teh starting feedstock unchanged but the output mixture contains a higher number of double bonds and aromatic rings. The basic petroleum feedstock is converted into a mixture of products of which the principal components are benzene, toluene and xylene (the process is often referred to as the BTX process). Benzene and other aromatics are isolated in the pure state from the output of the reformer by solvent extraction and fractional distillation. The relative proportions of benzene derived from the two sources vary from one operator to another but, in the later calculations, when the precise mix is unknown - as for example, when benzene is purchased on the open market - it is assumed that 50% is derived from each source. For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the year 1989-1995. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Data were supplied from 14 major benzene producers in Belgium, France, Germany Italy, Netherlands and UK. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Methodology report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Results are based on data supplied by 14 benzene production plants in 6 countries: Belgium, France, Germany, Italy, Netherlands and UK. Their total production was 3,2 million tonnes.

Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following general co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

Flow Data

General Activity QMetaData

Date Conceived	1989-1995
Data Type	Derived, mixed
Represents	See 'Function'
Method	European average data. Results are based on data supplied by 14 benzene production plants in 6 countries: Belgium, France, Germany, Italy, Netherlands and UK. Their total production was 3,2 million tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstram raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. Data from APMEs website www.lca.apme.org have been downloaded as exe-files. The files are opened and imported into Microsoft Excel. Further, the data from MS Excel is exported to a MS Access database.
Literature Reference	APME - Association of Plastics Manufacturers in Europe, website: http://lca.apme.org
Notes	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature used by CPM (CPM 2000:2). The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New names: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', report for benzene. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. --- Documented by Caroline Sjöberg and Sofia Haargaard, Volvo Technological Development Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 27 November 2001 --- Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 5 September 2001 ---
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses. 1. Provide APME member companies with information which will highlight potential areas for improving manufacturing processes 2. Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies - Internal company benchmarking - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	APME - Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels Belgium.
Practitioner	Boustead, Ian - .

Reviewer	-
Applicability	European average data. Results are based on data supplied by 14 benzene production plants in 6 countries: Belgium, France, Germany, Italy, Netherlands and UK. Their total production was 3,2 million tonnes. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for benzene production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data are probably fairly representative for production of benzene in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Note that emissions <0,5 mg (0,25 mg in data table) may be far below 0,5 mg in some cases. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission = 3,67 x {mass fraction of carbon in fuel}/{calorific value in MJ/kg} (kg/MJ fuel).

SPINE LCI dataset: Production of Blister Copper

Administrative	
Finished	Y
Date Completed	1998
Copyright	The International Copper Association
Availability	Public

Technical System	
Name	Production of Blister Copper
Functional Unit	1 kg of Blister Copper
Functional Unit Explanation	The purity of copper is approximately 98.5%.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	Data received for this study are based on pyrometallurgical operations only. This activity includes: 1) Copper ore mining; 2) Copper ore concentrate preparation and delivery; 3) Production of matte copper and 4) Production of blister copper. Production and use of electricity and fuel used in the processes are included. Below is a description of the included operations. -- 1) Ore mining --

	The copper ore mining method used is determined by the size, shape and depth below the surface of the ore body. Most copper ores are mined by open pit mining in which large quarries are opened, the ore broken away from the deposits by use of explosives and shovelled into trucks. Actual energy requirements vary widely depending on the characteristics of the mine and ore handling techniques used. The type and the amount of ore deposit and the overlying rock and dirt and the depth of the seam below the surface, affect the level of energy needed for mining the ore. The data for copper mining have been received from three mining companies. The data cover the mining of 45 million tonnes of ore. -- 2) Ore concentrate preparation and delivery -- It is normal practice for mining companies to prepare or concentrate before shipping to reduce the amount of material to be transported. The data mainly relates to transportation of ore concentrate by rail and sea. Transporting the concentrate by sea is exstensive. It is assumed that average shipping and rail transport distances were 10 000 km and 500 km respectively. The data cover preparation of 2 million tonnes of concentrate -- 3) Production of matte copper -- Here the ore concentrate, mixed with flux and other additives, is charged in a fuelfired smelting furnace where it is melted. The molten mass is allowed to separate into two layers. The upper slag layer, made up of iron silicate with less than 0,5% of copper, is normally discarded. The lower matte layer, with about 40% to 75% of copper, and containing most of original metal present, is transferred to the converting step to produce blister copper. -- 4) Production of blister copper -- During the production of blister copper the matte is converted to blister in a converter by oxidation in two stages. In the first stage iron sulphide is oxidised and fluxed to form slag which may contain copper (1-5%). The converter slag is ususally recycled back to the smelting furnace. With all the iron removed, the remaining copper sulphide is further oxidised to blister copper.

System Boundaries

Nature Boundary	Some of the data on air and water emissions was provided in a form which made it impractical to calculate emissions for unit mass of product output. For example, from an air emission value given in the units of mg/m3 of air, it is not possible to calculate the total emission unless the total volume of air is known and this is seldom measured in pactice. Therefor, where available, only emission values associated with the given amount of product made are used.
Time Boundary	The data comes from mining companies and producers of primary copper for the operations during the 12 month period in 1995 (information why the year 1995 was chosen is not available).
Geographical Boundary	The data comes mainly from European operations. Futher information of the geographical boundaries is not available.
Other Boundaries	The copper producing industry is international.
Allocations	The first thing that has been done to analyse this system is to break down the complex system into a series of separate sub-systems each of which produces a single product but which, when added together, exhibit the same charateristics as the original single system. In this study has co-product allocation and Stoichiometric allocation been applied. It is not often that practical processes exactly match for example the stoichiometric rules and an alternative method using mass must be applied.
Systems Expansions	Not applied

Represents	See 'Function'
Method	An LCA calculation of Blister Copper production. The tables that have been used are the tables 52, 54, 55, 56 and 57 in the Eco- profiles of Primary Copper. A report for The International Copper Association, January 1998. For the following subjects has a slightly different name been use here in SPINE compaired from the original tables in the IAC report: In SPINE: In the IAC report: Iron Ore Iron Natural Gas Gas/Condensate NaCl Sodium Chloride HC Hydrocarbons CH4 Methane Cu Cu++/Cu+++ Calcium Ca++ NO3-N NO3- Hazardous waste Regulated chemical
Literature Reference	Eco- profiles of Primary Copper. A report for The International Copper Association, January 1998.
Notes	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow

	with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature used by CPM (CPM 2000:2). The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New names: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.

About Inventory	
Publication	Ecoprofile of Primary Copper Production- A report for The International Copper Association By Dr. I. Boustead. 1998. -- Data documented by: Sofia Medin, Electrolux ESD Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	LCA practitioners
General Purpose	The purpose of this work was to produce life-cycle inventory data for the production of primary copper and the sub-processes based on data submitted by members of the International Copper Association from their own operations.
Detailed Purpose	The aim is to provide ''cradle to gate'' data for the production of blister copper, which is a sub-process in the production of primary copper
Commissioner	- The International Copper Association .
Practitioner	Boustead, Ian Dr - .
Reviewer	
Applicability	There is no recommendation of how to use the data from this report. This activity is part of a ''cradle to gate'' system for primary copper production. In the sequence of operations leading up to primary copper production there are six main stages involved. These are 1) Copper ore mining; 2) Copper ore concentrate preparation and delivery; 3) Production of matte copper; 4) Production of blister copper; 5) Production of copper anodes and 6) Production of primary copper. This activity only covers the stages 1) copper ore mining, 2) copper ore concentrate preparation and delivery, 3) Production of matte copper and 4) Production of blister copper. All six stages in the primary copper production have been described cumulatively in separate activities in the database.
About Data	The data used for electricity and fuel production in the calculations leading to the results reported comes from the reports of International Energy Agency. Data Assumtions: Data received from participating companies show sometime wide variation with respect to metal contents of ore and various intermediate products such as concentrates, gas dust and scrap. Therefor has the following assumptions been made: 1. Copper content in ore. Where actual data on copper content of the ore were available these were used. Otherwise the content was calculated on the basis of mass flow. 2. Copper content of matte according to published literature is between 40% to 75%. The assumption made, where the copper content in matte was not derived from mass flow, is therefor 60 %. 3.Average copper content of blister was assumed to be 98,5%, based on published litterature. 4. There is also some loss of copper during ore preperation and the smelting and recovery processes. The loss can be calculated from the mass flow if accurate contents of the input and output materials where known.Where this is not possible, the loss is assumed to be 1% at each step of the sequence of operations. It is further assumed that there is another 4% loss of copper during the operational steps from ore preperation to electro-refining, making the total loss of copper to 5%.
Notes	The results of the Ecoprofile study has been broken down into a number of categories, identifying the type of operation that gives rise to them. The categories are: 1. Fuel production 2. Fuel use 3. Process 4. Transport 5. Biomass (inputs and outputs associated with the use of biological materials such as wood)

SPINE LCI dataset: Production of brass cages used for spherical roller bearings

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Production of brass cages used for spherical roller bearings
Functional Unit	One brass cage, 55,6 kg
Functional Unit Explanation	One spherical roller bearing 232/530 consists of following components: 1. one inner ring 2. one outer ring 3. one guide ring 4. one brass cage 5. 36 rollers (coated or non-coated) The functional unit for this process is one brass cage. The data can finally be used (together with data for the other ingoing components) to calculate environmental impact for a complete spherical roller bearing 232/530 Dimensions of the bearing: di= 530 mm dy= 980 mm breadth= 355 mm The activities for the production of the other ingoing components are also available at SPINE@CPM: * Production of bearing rings * Production of bearing rollers (á 9.2 kg) * Production of guide rings used for spherical roller bearings and the activity for the production of a complete SRB 232/530 can be found as: * Production of SKF Spherical Roller Bearing 232/530
Process Type	Gate to gate
Site	SKF Sverige AB415 50 GÖTEBORG
Sector	Materials and components
Owner	SKF Sverige AB415 50 GÖTEBORG
Technical system description	Production of one brass cage CS 232/530 CAM, 55,6 kg. This cage is to be mounted into the SKF spherical roller bearing 232/530. The brass cage has the function of keeping the rollers separated in the bearing. The cage is made at SKFs site in Göteborg. The raw material is brass cylinders supplied by BecoTek AS in Norway. The brass for their production in Norway is bought from Olof Manners AB in Mölndal, Sweden. The production of brass is not included in this dataset, but must be followed from the cradle for a total environmental impact. The transport of brass from Mölndal in Sweden to Åmot in Norway is NOT included in the dataset. The following process steps are included in this dataset: (1 and 2 are described in separate activities in the SPINE@CPM database) 1. Production of turned brass cylinders, 205 kg. 2. Manufacturing of brass cages at SKFs site in Göteborg. 3. Transport of brass scrap from SKF in Göteborg to Västerås (where the brass is recycled at Nordic Brass AB). The mineral oil in the cutting fluid used at SKFs site in Göteborg is followed from the cradle with the activities: 4. Extraction of crude oil 5. Refining of crude oil And to the grave with the activity: 6. Combustion of waste oil Also the transport is considered: 7. Transport of cutting fluid emulsion from Göteborg to Halmstad where the cutting fluid emulsion is burnt. Diesel production and electricity production (Swedish average for manufacturing of brass

	cages at SKFs site in Göteborg, and European average for the production of turned brass cylinders) ARE included for the activities. --- First the brass is smelted in electric furnaces at the plant in Åmot, Norway. The smelt is then poured into a form and casted into desired shape. The cylinders formed are then turned in a turning machine and finally inspected and packed. All scrap produced in the process is recycled and used in the smelting process as raw material. The energy consumption was reported from BecoTek (= 1.19 kWh/kg). Also internal transport by electric truck (40 m for each cylinder) and diesel truck (40 m for each cylinder) were reported. The environmental impact is probably significantly higher since no other inflows or outflows from the process are measured. The brass cylinders are transported to SKF in Göteborg by truck. (weight of the turned brass cylinder is 205 kg) (this transport is NOT included in the dataset) At the SKF plant in Göteborg the brass cylinders are treated and processed in several steps to obtain the desired shape. 1. First the cylinders are turned in the Morando lathe. 2. The cylinders are then drilled. The drilling takes about 93 minutes and is the most time consuming step in the process. 3. To get rid of sharp edges from the drilling, the cages are then ground by hand. 4. The last step is to trumble the cages with trumble chips made of ceramic stones to get a smooth surface. The cages are then transported, by industrial trucks, to the C-factory at SKF where the final assembly into the SKF Spherical Roller Bearing 232/530 takes place. (1 km electric truck transport is included) The trumbling chips are NOT included in this study, since the amount of chips needed for one cage was insignificant. Also the energy consumption for the trumbling of the cages was neglected since it is very small in comparison to the energy consumption of the other process equipment. The brass-scrap from the SKF process is transported to Västerås, Sweden, for complete recycling. The cutting fluid is transported to Halmstad for destruction and use as energy source in the Cement-industry.

System Boundaries	
Nature Boundary	The production of brass is not included in this study, so the inflow of brass is coming from the technosphere. This MUST be accounted for when using this dataset. (Data from brassproduction is available e.g. from CIT Ekologik AB, Chalmers) Emissions to water and air are not known for the production of turned brass cylinders in Norway. Only energy consumption (1,19 kWh/kg brass) and internal transport (40 m electric truck and 40 m diesel truck) are included from that process . From SKF no emissions to air are included since they were not known and measured. The trumble chips are not followed from the cradle and not to the grave. The brass scrap that leaves the system is considered to be a co-product since it is used as raw material for new products and thus the boundary is the technosphere. The mineral oil in the cutting fluid has been accounted for. The cutting fluid is an emulsion with water and 4% of CASTROL SW 3420. According to the product data sheet for CASTROL SW 3420 it contains of 40% mineral oil. Databases for ''Extraction of crude oil'' and ''Refining of crude oil'' from SPINE@CPM have been used for tracing the mineral oil to its cradle. The activity ''Combustion of waste oil'' has been used for following the mineral oil to its grave. This is also a separate activity that can be found in SPINE@CPM database. When calculating the transport of cutting fluid from Göteborg to Halmstad the cutting fluid is not yet separated. This means that the weight of water is also included in ''cargo''.
Time Boundary	The data is collected during autumn 2002. No changes in the procedure are planned for the nearest future.
Geographical Boundary	The brass cylinders are produced in Åmot, Norway. The manufacturing of cages takes place at SKF in Göteborg, Sweden. The final disposal of brass and waste oil takes place in Sweden (Västerås and Halmstad).
Other Boundaries	The transports from Göteborg to Halmstad (cutting fluid emulsion) and from Göteborg to Västerås (brass scrap) are included with diesel production. In the activity ''Manufacturing of brass cages at SKFs site in Göteborg'' also internal transport within SKF industrial area 1 km electric truck is included and the electricity production needed for this (0,75 kWh/km). Internal transport (40 m electric truck and 40 m diesel truck) are included for the production of turned brass cylinders in Norway. Assumptions were made at BeTe Trucks AB in Sweden how much energy a dieseltruck and an electric truck consume per km (=0,75 KWh/km (el) and 0,3 litre/km (diesel)). The heating value for diesel (=35, 31 MJ/litre) was found at Internet: www.fast-tech.com and the diesel consumption could be calculated to 0,42372 MJ/40m. The diesel production is included in the dataset. All electricity production is included. Average European electricity is used for the activity '' Production of turned brass cylinders'' at BecoTek in Norway and Swedish average electricity is used for the activity ''Manufacturing of brass cages at SKFs site in Göteborg''. The refining of crude oil is assumed to take place in Sweden and thus Swedish average electricity production is used for this activity.

Allocations	Allocations have been made according to weight for the Production of turned brass cylinders in Norway. For the process at SKF in Göteborg the data is production specific to the specific cage. The time in the different process equipment can vary for different cages of different dimensions, and thus also energy consumption varies. The cutting fluid used in the process is allocated according to weight.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	02-08-01 - 02-12-31
Data Type	Derived, mixed
Represents	
Method	The data from the manufacturing of cages at SKF has been collected during a visit at the specific production site and from interviews with the production manager Christer Landgren. Much of the data is monitored e.g the consumption of cutting fluid, and the processing time for the cages in the diffferent process equipment. The brass cage is weighted before and after, to understand how much scrap is produced. For the production of brass cylinders in Norway at Beco Tek, the energy consumption is estimated by Eirik Hjerpaasen. Data for the production of brass is taken from a CIT database. For more specific information see under the sub activities: ''Production of turned brass cylinders'' and ''Manufacturing of brass cages at SKFs site in Göteborg''.

About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Thechnology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Data reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The data is valid for production of brass cages of this dimension at the specific site at SKF in Göteborg, Sweden. Note that the transportation of cutting fluid (Gbg-Halmstad) and brass scrap (Gbg-Västerås) must be the same since these transports are included in the dataset. The data can be used (together with data for the other ingoing components) to calculate environmental impact for a complete SKF spherical roller bearing 232/530. The activities for the production of the other ingoing components are also available at SPINE@CPM: * Production of bearing rings * Production of bearing rollers (á 9.2 kg) * Production of guide rings used for spherical roller bearings and the activity for the production of a complete SRB 232/530 can be found as: * Production of SKF Spherical Roller Bearing 232/530
About Data	Data is gathered from interviews with Eirik Hjerpaasen at BecoTek AS, Norway and Christer Landgren at SKF Sverige AB.
Notes	

SPINE LCI dataset: Production of butadiene

Administrative	
Finished	Y
Date Completed	1999-01-01
Copyright	APME
Availability	Public

Technical System	
Name	Production of butadiene
Functional Unit	1 kg butadiene
Functional Unit Explanation	Butadiene is a C4-hydrocarbon with two double bonds, which makes it very reactive. Butadiene is mainly used for producing PB, ABS, SB-rubber, nitrile rubber and chloroprene. Butadiene is a product mainly from steam cracking of naphta.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. Production of butadiene include all major operations from extraction of crude oil and gas to catalytic reforming of naphtha, solvent extraction and fractional distillation. A significant part of the butadiene used in Europe is derived directly from the steam cracking of natural gas or the naphta fraction of crude oil. Cracking is a three-stage process wich includes the steps: furnace, quench (for cooling) and separation (fractional distillation). In addition to butene isomers, the process also produces ethylene, propylene and a number of other hydrocarbons. Some of these will be extracted and some will be fed back to the furnace. An alternative source of butadiene is the dehydrogenation of the mixed butene fraction from steam cracking. The butenes are first purified to remove any non-C4 hydrocarbons and the iso-butene is removed with sulphuric acid. The mixture of 1- and 2-butene are mixed with steam and heated when the conversion to butadiene rapidly occurs in the presence of an iron oxide or calcium nickel phosphate catalyst. In addition to the mentioned sub-processes, the following major processes are included: Crude oil extraction and delivery; oil refining for naphtha (fractional distillation); natural gas extraction, processing and deliver; coal mining and delivery. Also electricity production and production of other raw materials have been included on a cradle to gate basis, i.e. all materials and energies have been tracked back to the extraction of raw materials from the earth. Operating conditions: As the data are based on information from 4 plants in 3 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. For raw materials, inputs as listed from APME, have been reocorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries	
Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values.

	Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the year 1989-1995. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Results are based on data supplied by 4 butadiene production plants in 3 countries: Italy, Netherlands and UK. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Metholodogy report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Data were supplied from 4 butadiene production plants in UK, Netherlands and Italy. Their total production was 452,000 tonnes. .
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following general co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

Flow Data

General Activity QMetaData

Date Conceived	1989-1995
Data Type	Derived, mixed
Represents	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been

	translated into the nomenclature by CPM (CPM 2000:2). The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New name: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.
Method	European average data. Results are based on data supplied by 4 butadiene production plants in 3 countries: UK, Netherlands and Italy. Their total production was 452,000 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied whereever there have been sufficient data from upstream raw material and fuel producers. In verticall averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the caluclations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emissions. For fuels and feedstock materials, actual gross calorific values (energy conten) have been used in teh calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. Data from APMEs website www.lca.apme.org have been downloaded as exe-files. The files are opened and imported into Microsoft Excel. Further, the data from MS Excel is exported to a MS Access database.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', report for Butadiene. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME´s web site http://lca.apme.org. -- Documented by: Sofia Boström, Volvo Technological Development Corporation Documentation reviewed by: Ann-Christin Pålsson, IMI, Chalmers University of Technology Published in SPINE@CPM: 24 May 2002 --
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to butadiene.
Detailed Purpose	Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses. 1. Provide APME member companies with information which will highlight potential areas for improving manufacturing processes 2. Provide valuable inventory data for downstream users of butadiene, for instance plastic manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: -Plastic waste management stidues - Internal company benchmarking - Product development. Detailed environmental information to customers of APME memebers for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-1993, the period to which the oldest group of Eco-profiles data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	APME - .
Practitioner	Ian Boustedt - .
Reviewer	
Applicability	European average data. Data were supplied from 4 butadiene producers in UK, Netherlands and Italy. Their total production was 432,000 tonnes. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison

	between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for butadiene production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data are probably fairly representative for production of butadiene in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission = 3,67 x {mass fraction of carbon in fuel}/{calorific value in MJ/kg} (kg/MJ fuel).

SPINE LCI dataset: Production of cameras, magazines and accessories

Administrative	
Finished	Y
Date Completed	1996-03-01
Copyright	
Availability	Public

Technical System	
Name	Production of cameras, magazines and accessories
Functional Unit	camera and 1,77 magazines
Functional Unit Explanation	The environmental load per produced camera and 1,77 magazines. There is also a production of accessoires that is not included in the functional unit. This is not a good functional unit because the basic components, such as metal plates etc, used in the production are not included. The optics are bought and not included.
Process Type	Gate to gate
Site	Victor Hasselblad AB Box 220 401 23 Göteborg Sweden
Sector	Consumer goods
Owner	Victor Hasselblad AB Box 220 401 23 Göteborg Sweden
Technical system description	Victor Hasselblad AB produces cameras, magazines and accessories. The main process consists of surface treatment of the material used in the cameras. The processes are chromium-plating, eloxering, nickel-plating, cadmium-plating, gold-plating, tumbling, degreasing and painting. The plates are shaped in the mechanical work shop. DETALIED DESCRIPTION The materials used for the components to the camera are aluminium, brass, steel, stainless steel and a small amount of magnesium. In the mechanical work-shop the components are shaped. SURFACE TREATMENT The surface treatment is the part of the productrion that is the most hazardous to the environment. All rinsing water and other leakage that may occur in the processes is led to the internal purification plant. The processes used are the following: Chromium-plating, eloxering, nickel-plating, cadmium-plating, gold-plating, tumbling, degreasing and painting. Chromium-plating: The goods that are plated with chromium is made of aluminium, brass or steel. The tubs

	contain 1-1,5 m3. The rinsing water is controlled manually, with a rotameter, exept for the rinse after the chrome, where a conductivity meter has been installed. Anodizing: The goods treated are made of aluminium and stainless steel. The black coloured bath is recirculated continiously through a filter. The rinsing water is controlled manually, with a rotameter, exept for the postpackning bath, where a conductivity meter has been installed. Nickel-plating: All the tubs contain 0,7 m3. Only aluminium is trated. The nickel and the copper baths are recirculated continiously through a filter. The rinsing water from the nickel-plating is secluded, so that no water is let out. The rinsing water is controlled manually, with a rotameter. Cadmium-plating: All the tubs contain 0,7 m3. Magnesium, brass and steel goods are plated. The rinsing water is controlled manually, with a rotameter. Gold-plating: Aluminium, brass, steel and stainless steel goods are plated with gold. The rinsing water is controlled manually, with a rotameter. The nickel bath is recirculated continiously through a filter. Trumbling: The goods that are trumbled consist of detaljs of aluminium (65%), brass (20%), steel (10%) and magnesium (5%). The rinsing water consist of fresh water from the municipal. Cooling water is kept in a cooling tank and used as rinse water. Degreasing: Degreasing with organic solvents is done in one machine, and alcaline degreasing in two machines. Rejected water is led to the internal purification plant. In the mecanical woorkshops there is a tricleaner, which is used occasionally. The cleaner has no recycling equipment. (The cleanber is planed to be taken out of production during 1995.) Painting: There are five spray boothes with water curtains at the department of lacquering. The system is secluded, and empied by RECI. There is also a convection kiln used to fire lacquered goods, and a belt furnace used to IR-fire lacquered goods. The finished components are assembled into cameras, magazines and accessories.

System Boundaries

Nature Boundary	The company is not obligated to state other emission- or waste substances than the Swedish Environmental Protection law requires.
Time Boundary	The company is obligated to write an Environmental report once every year. Though the legislated limits can be changed only if the activity is changed.
Geographical Boundary	Sweden
Other Boundaries	Only the painting and surface treatment departments are accounted for in the environmental report.
Allocations	
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1995
Data Type	Unspecified

Represents	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature by CPM (CPM 2000:2). The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New name: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.
Method	Study the environmental report The data in the table has been converted into amounts per functional unit. The data from the environmental report has therefore been devided by the annual production for 1995. The total production during 1995 is 13 000 cameras, 23 000 magazines and accessoires.
Literature Reference	Environmental report for Victor Hasselblad AB from 1996, The Environmental Administration in the municipality of Göteborg, Sweden Some information has been gathered through personal communication with Stig Wilén, Victor Hasselblad AB.
Notes	The average pH during 1995 was 8,5 and the average flow of waste water is 50 m3/day.

Date concieved: 1995 Data type: Monitored data, discrete Method: The arithmetic average value is given by five spiecements. Each spiecement is accumulated during two mounth. The aluminium is analysed according to Swedish standard ss 028152-2 by the laboratory KM-Lab (Box 1083, 581 10 Linköping, Sweden, Phone +46 (0)13 233600). The result is shown as a concentration, but given the two mounth waterflow it is converted to an amount representing the measuring periode. The five amounts sums up to the total emission for 1995. The instrument for taking of spiecements is controlled and calibrated continously. Three employees has passed a course in taking of spiecements. Notes: The water is led to Ryaverket (the local sewage treatment works).	Output	Emission	Al	2180			mg	Water	
Date concieved: 1995 Data type: Monitored data, discrete Method: The arithmetic average value is given by five spiecements. Each spiecement is accumulated during two mounth. The cadmium is analysed according to Swedish standard ss 028152-2 by the laboratory KM-Lab (Box 1083, 581 10 Linköping, Sweden, Phone +46 (0)13 233600). The result is shown as a concentration, but given the two mounth waterflow it is converted to an amount representing the measuring periode. The five amounts sums up to the total emission for 1995. The instrument for taking of spiecements is controlled and calibrated continously. Three employees has passed a course in taking of spiecements. Notes: The water is led to Ryaverket (the local sewage treatment works).	Output	Emission	Cd	17.6			mg	Water	
Date concieved: 1995 Data type: Monitored data, discrete Method: The arithmetic average value is given by five spiecements. Each spiecement is accumulated during two mounth. The chromium is analysed according to Swedish standard ss 028152-2 by the laboratory KM-Lab (Box 1083, 581 10 Linköping, Sweden, Phone +46 (0)13 233600). The result is shown as a concentration, but given the two mounth waterflow it is converted to an amount representing the measuring periode. The five amounts sums up to the total emission for 1995. The instrument for taking of spiecements is controlled and calibrated continously. Three employees has passed a course in taking of spiecements. Notes: The water is led to Ryaverket (the local sewage treatment works).	Output	Emission	Cr	1330			mg	Water	
Date concieved: 1995 Data type: Monitored data, discrete Method: The arithmetic average value is given by five spiecements. Each spiecement is accumulated during two mounth. The copper is analysed according to Swedish standard ss 028152-2 (margin of error +/- 5-20%)	Output	Emission	Cu	464			mg	Water	

by the laboratory KM-Lab (Box 1083, 581 10 Linköping, Sweden, Phone +46 (0)13 233600). The result is shown as a concentration, but given the two mounth waterflow it is converted to an amount representing the measuring periode. The five amounts sums up to the total emission for 1995. The instrument for taking of spiecements is controlled and calibrated continously. Three employees has passed a course in taking of spiecements. Notes: The water is led to Ryaverket (the local sewage treatment works).									
Date concieved: 1995 Data type: Monitored data, discrete Method: The arithmetic average value is given by five spiecements. Each spiecement is accumulated during two mounth. The nickel is analysed according to Swedish standard ss 028151 by the laboratory KM-Lab (Box 1083, 581 10 Linköping, Sweden, Phone +46 (0)13 233600). The result is shown as a concentration, but given the two mounth waterflow it is converted to an amount representing the measuring periode. The five amounts sums up to the total emission for 1995. The instrument for taking of spiecements is controlled and calibrated continously. Three employees has passed a course in taking of spiecements. Notes: The water is led to Ryaverket (the local sewage treatment works).	Output	Emission	Ni	2940			mg	Water	
Date concieved: 1995 Data type: Monitored data, discrete Method: The arithmetic average value is given by five spiecements. Each spiecement is accumulated during two mounth. The led is analysed according to Swedish standard ss 028152-2 by the laboratory KM-Lab (Box 1083, 581 10 Linköping, Sweden, Phone +46 (0)13 233600). The result is shown as a concentration, but given the two mounth waterflow it is converted to an amount representing the measuring periode. The five amounts sums up to the total emission for 1995. The instrument for taking of spiecements is controlled and calibrated continously. Three employees has passed a course in taking of spiecements. Notes: The water is led to Ryaverket (the local sewage treatment works).	Output	Emission	Pb	124			mg	Water	
Date concieved: 1995 Data type: Monitored data, discrete Method: The arithmetic average value is given by five spiecements. Each spiecement is accumulated during two mounth. The zink is analysed according to Swedish standard ss 028152-2 by the laboratory KM-Lab (Box 1083, 581 10 Linköping, Sweden, Phone +46 (0)13 233600). The result is shown as a concentration, but given the two mounth waterflow it is converted to an amount representing the measuring periode. The five amounts sums up to the total emission for 1995. The instrument for taking of spiecements is controlled and calibrated continously. Three employees has passed a course in taking of spiecements. About Inventory

Publication	The environmental report from Victor Hasselblad AB for 1995, The Environmental Administration in the municipality of Göteborg -- Data documented by: Maria Erixson and Sara Ågren, project employed for the database projet at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	To show the environmental load
General Purpose	The purpose of the Environmental report is to be the base for permission trial of activities that is harmful to the environment and further to make shore that the company comply with the decision.
Detailed Purpose	To control that the legislated limits are not exceeded.
Commissioner	- Swedish government via The Board of County in Göteborg and Bohus or The Environmental Administration in the municipality of Göteborg. .

Practitioner	Wilén, Stig - Victor Hasselblad AB Box 220 401 23 Göteborg Sweden.
Reviewer	- Swedish government via The Board of County in Göteborg and Bohus or The Environmental Administration in the municipality of Göteborg.
Applicability	The material used (optics and metal plates) for making cameras, magazines and accessories are not stated in the environmental report. Only the material used for treating the components are specified. For more information about the purchased amounts of material contact the company.
About Data	The average pH during 1995 was 8,5 and the average flow 50 m3/day.
Notes	

SPINE LCI dataset: Production of CAN fertiliser

Administrative

Finished	Y
Date Completed	1999-01-25
Copyright	
Availability	Public

Technical System

Name	Production of CAN fertiliser
Functional Unit	1 kg of CAN fertiliser
Functional Unit Explanation	Suprasalpeter, N 28 (27,6 % N) Calcium ammonium nitrate (CAN)
Process Type	Gate to gate
Site	Hydro Agri AB Box 516 SE-261 24 Landskrona Sweden
Sector	Materials and components
Owner	Hydro Agri AB Box 516 SE-261 24 Landskrona Sweden
Technical system description	At the plant operated by Hydro Agri AB in Landskrona nitric acid is mixed with gaseous ammonia, forming an ammonium nitrate solution of 92 %. The solution is evaporated with steam generated in the nitric acid plant to a concentration of 96 % in a vacuum evaporator. Process steam from the exothermic neutralisation of ammonia and nitric acid contains some ammonia and ammonium nitrate droplets. The main part of the droplets is separated in a cyclone followed by a Brink mist filter and the nitrogen is brought back to the process. The treated steam from the neutralisation and steam from the vacuum evaporator are condensed with cooling water. The heated cooling water is then partly used for internal heating and partly transported to a district-heating network. The condensate is then treated in an osmosis set-up to partition the nitrogen compounds into one of two parts. The minor part containing nitrogen compounds is used as process water in the nitric acid plant and the other part is let out from the plant. The ammonium nitrate solution is mixed with small amounts of sulphuric acid for pH regulation and dolomite in a Frieder-King blender. The warm solution is then granulated with dolomite, crushed recycled material, dust from the dustfilter and in some cases calcium sulfate (gypsum). The granulate is then put into a rotary drier where the material is dried using hot air. Lastly the material is screened, cooled and coated. Air from the rotary drier, rotary coolers and from general dust extraction operations contains product dust and small amounts of ammonia. Most of the dust is separated in two textile filter barriers and the remaining tailgas is then released from the plant in a stack, 25 m above the roof of the plant. Reference: Miljörapport Hydro Agri AB Landskrona (1998). Official environmental report. Hydro Agri AB, Box 516, 261 24 Landskrona

System Boundaries

Nature Boundary	The system starts at the incoming factory gate and ends at the outgoing factory gate, i.e production of electricity, steam and supply materials are not included in this dataset.
Time Boundary	The data are figures for production in 1997.
Geographical Boundary	Hydro Agri AB in Landskrona, Sweden.
Other Boundaries	
Allocations	Total amount of emissions of ammonia to air were divided by total amounts of nitrogen in the fertilisers produced in1997 and then multiplied by nitrogen content of the product. An average value for emissions of particulates (fertiliser dust) to air was given in mg/h and the assumed yearly operating time was 85% of the time of year. Total emissions per year were then calculated and divided by total amounts of fertiliser produced in 1997. Total amount of nitrogen (NO-3-N, NH4+-N) in the water leaving the site includes, besides emissions of nitrogen from the processes also nutrient leakage from the nearby area. The amount of nitrogen released from the nitric acid plant, the fertiliser plant and the chemical storage was subtracted from the total amount. The share of the remaining amount originating from nutrient leakage was assumed to be 60% and 40% was assumed to originate from fertiliser dust. The share coming from nutrient leakage was not included in the total amounts of emissions, which then were divided by the total amount of nitrogen in fertiliser produced in 1997 and multiplied by the nitrogen content of the product. Production of district heat arise from neutralisation of nitric acid with ammonia and total amount of district heat produced at the fertiliser plant was therefore divided by the total amount nitrogen in the fertilisers produced in 1997 and then multiplied by the nitrogen content of the fertiliser product. Total amounts of steam and electricity consumed in the fertiliser plant was divided by total amounts of fertilisers produced in 1997.
Systems Expansions	Not applicable.

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature by CPM (CPM 2000:2). The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New name: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.
Method	Amounts of ammonia and nitric acid consumed in the production of fertiliser was calculated by using the nitrogen content of the product and the molecular mass of nitric acid and ammonia respectively. Example: M(N): 14 g/mole M(NH3): 17 g/mole Þ 0.28 * (17g/mole) / (14 g/mole) /2 = 0.17 t NH3/t fertiliser Amount of dolomite consumed due to the fertiliser production was calculated by subtracting the amount of nitric acid and ammonia consumed from the amount fertiliser produced. Example: 1 - 0.17 t NH3/t fertiliser - 0.63 t HNO3/t fertiliser = 0.20 t dolomite /t fertiliser Total amount of emissions of ammonia to air were divided by total amounts of nitrogen in the fertilisers produced in1997 and then multiplied by nitrogen content of the product. An average value for emissions of particulates (fertiliser dust) to air was given in mg/h and the assumed yearly operating time was 85% of the time of year. Total emissions per year were then calculated and divided by total amounts of fertiliser produced in 1997. Total amount of nitrogen (NO-3-N, NH4+-N) in the water leaving the site includes, besides emissions of nitrogen from the processes also nutrient leakage from the nearby area. The amount of nitrogen released from the nitric acid plant, the fertiliser plant and the chemical storage was subtracted from the total amount. The share of the remaining amount originating from nutrient leakage was assumed to be 60% and 40% was assumed to originate from fertiliser dust. The share coming from nutrient leakage was not included in the total amounts of emissions, which then were divided by the total amount of nitrogen in fertiliser produced in 1997 and multiplied by the nitrogen

	content of the product. Production of district heat arise from neutralisation of nitric acid with ammonia and total amount of district heat produced at the fertiliser plant was therefore divided by the total amount nitrogen in the fertilisers produced in 1997 and then multiplied by the nitrogen content of the fertiliser product. Total amounts of steam and electricity consumed in the fertiliser plant was divided by total amounts of fertilisers produced in1997. See also ''Specific QMetaData''.

About Inventory

Publication	Davis J, Haglund C (1999). ''Life Cycle Inventory (LCI) of Fertiliser Production - Fertiliser Products Used in Sweden and Western Europe''. SIK report no. 654. The Swedish Institute for Food and Biotechnology (SIK). Gothenburg, Sweden. -- Data documented by: Jennifer Davis, SIK (The Swedish Institute for Food and Biotechnology). Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The data are intended to be us
General Purpose	To generate an inventory of emissions and use of resources due to the production of fertilisers used in Sweden.
Detailed Purpose	The purpose was not to compare the production of different fertilisers with each other, but to generate a thorough inventory of emissions and use of resources due to the production of different mineral fertilisers. The data are intended to constitute a useful basis of input information in life cycle assessments of food production systems.
Commissioner	- SIK AB, The Swedish Institute for Food and Biotechnology Box 5401 SE-402 29 Gothenburg Sweden .
Practitioner	Davis, Jennifer and Caroline Haglund - SIK AB Box 5401 402 29 Gothenburg Sweden.
Reviewer	-
Applicability	The data are applicable for production of CAN fertiliser produced and used in Sweden. It can be assumed that production of CAN in Sweden is representative for production of all CAN that is used in Sweden, but it is important to be aware of the fact that there may exist imports of CAN into Sweden.

	The dataset is included in an aggregated system for fertiliser production in Landskrona (cradle to gate).
About Data	The data are taken from a specific site in Sweden and are therefore reliable. The data are gathered from the official environmental report distributed by Hydro Agri AB in Landskrona and also from personal communication with people working there. There are only two sites in Sweden that produce CAN fertiliser and the site in Landskrona is representative for Swedish production of CAN.
Notes	Internal review of the report was performed by: Olle Ramnäs, CTH (Chalmers University of Technology), Berit Mattsson and Magnus Stadig, SIK (The Swedish Institute for Food and Biotechnology).

SPINE LCI dataset: Production of CAN fertiliser AGGR

Flow Chart

Technical System	
Name	Production of CAN fertiliser AGGR
Functional Unit	1 kg Nitrogen fertiliser
Functional Unit Explanation	
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The production route of CAN fertiliser produced at Hydro Agri AB in Landskrona can be seen in the aggregated activity window. For information about each separate production step, please see each included dataset. Emissions from transports, energy consumption and production of steam, district heat and electricity have been included in the system by using information and emission factors from the database in LCAiT 3.0. LCAiT 3.0 is a computer programme created by CIT Ekologik in Gothenburg for practitioners of life cycle assessments. Production/consumption of steam is assumed to replace/be produced by combustion of oil (efficiency of 0.90). Oil has been chosen as fuel source, as it in terms of emissions lies between coal and natural gas. Included transports and assumptions made regarding transports are described below (transports cannot be seen in the aggregated activity window). The ammonia used in production of fertilisers in Sweden is purchased at the spot market in the Baltic Sea. This ammonia mostly originates from Russia and Poland. The ammonia has been assumed to origin from the area around Moscow. It has been assumed that the ammonia is transported by train from Moscow to the harbour in Ventspils in Latvia (1000 km, train, diesel) and then transported by boat to Landskrona (400 km, ship, bulk carrier). Dolomite used at Hydro Agri AB in Landskrona comes from Hammerfall in Northern Norway. It is transported by truck (5 km, medium truck, rural, full) to a harbour close to Bodø, from where it is transported by boat (1800 km, ship, bulk carrier) to Landskrona.

SPINE LCI dataset: Production of clean bearing steel

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Production of clean bearing steel
Functional Unit	1000 kg ingot mould
Functional Unit Explanation	
Process Type	Gate to gate
Site	Ovako Steel AB SE-813 82 Hofors
Sector	Materials and components
Owner	Ovako Steel AB SE-813 82 Hofors
Technical system description	This activity is a process step included in the whole system activity ''Production of bearing rings'' and the system activity ''Production of bearing rollers (á 9.2 kg)'' (both can be found in the SPINE@CPM database). This gate-to-gate activity describes how steel ingot (used as raw material for bearing rings and rollers) is produced at the steel mill at Ovako Steel AB in Hofors. Roller bearings must be produced from extremely clean steel that possesses maximum fatigue strength. The steel produced at Ovako Steel AB in Hofors, Sweden, the raw material for the outer and inner rings, is completely produced from scrap. When the scrap arrives at Ovako Steel AB in Hofors it is sorted according to quality and alloy elements. The scrap is melted in an electric arc furnace where oxygen and carbon is added. The addition of oxygen and carbon makes the slag porous and in turn makes the process more effective. When the scrap is completely melted the slag is removed and the melt is poured into a ladle furnace where the steel is degassed and final adjustments of the alloys are made. The steel is then teemed uphill into ingot moulds. The moulds are finally removed. --- This dataset is an updated version of the previous dataset of ''Production of bearing steel''

	made by Åsa Ekdahl (also available at SPINE@CPM). Ovako Steel AB has made some improvements in the process and new data has been obtained for all process steps.

System Boundaries

Nature Boundary	The steel ingot is 100 % made from scrap and is not seen as a resource, but comes from the technosphere. The steel scrap from the process is recycled within the process and is not seen as waste, but a co-product to the technosphere.
Time Boundary	All data refers to year 1999. No changes are planned for the nearest future.
Geographical Boundary	The steel production takes place at the steel mill at Ovako Steel AB in Hofors, Sweden.
Other Boundaries	The electricity production is NOT included for the activity and must be followed from the cradle in order to get a correct result. The production of light fuel oil must be traced from the cradle, and is NOT included in this dataset. Production of raw material is not included. Waste treatment is not included. Subsystems concerning employees are not included. Transports are not included.
Allocations	Allocations have been made according to weight.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	02-08-01 - 02-12-31
Data Type	Derived, mixed
Represents	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature by CPM (CPM 2000:2). The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New name: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.
Method	The data has been gathered from interviews with the environmental manager Eva-Maria Arvidsson at OVAKO Steel AB in Hofors. Meassurements but also estimations has been made by her.
Literature Reference	Miljörapport Hydro Agri AB Landskrona (1998). Official environmental report. Hydro Agri AB, Box 516, 261 24 Landskrona Personal communication: Bertilsson G (1998). About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Data reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	LCA practitioners in general.
General Purpose	To fulfil a need for standard values to calculate energy use and exhaust emissions from production of clean bearing steel.
Detailed Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström. The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The data are applicable to the production of bearing steel at the Steel Mill at Ovako Steel in Hofors, Sweden.
About Data	Data is gathered from interviews with Eva-Maria Arvidsson at Ovako Steel AB in Hofors. This dataset is an updated version of the previous dataset of ''Production of bearing steel'' made by Åsa Ekdahl (also available at SPINE@CPM). Ovako Steel AB has made some improvements in the process and new data has been obtained for all process steps.
Notes	

SPINE LCI dataset: Production of cooling fluid, R134a

Administrative	
Finished	Y
Date Completed	1995
Copyright	IVF-Institutet för verkstadsforskning
Availability	Public

Technical System	
Name	Production of cooling fluid, R134a
Functional Unit	1 kg R134a
Functional Unit Explanation	1 kg of the cooling agent R134a, a gas at room temperature and 1 atm pressure.
Process Type	Cradle to gate
Site	Unspecified
Sector	
Owner	Unspecified
Technical system description	Production of cooling fluid R134a from cradle to gate (product), including most of the subsystems for the production. R134a is used as cooling fluid for refrigeratiors, AC systems in cars etc. It replaces the older R12 and has no impact on the ozonelayer. But it has a hight impact on the greenhouse effect (1300 times higher than CO2). Brief description ------------------------ This study includes the production of R134a and the production of the two components needed for the process: Hydrogenfluoride and trchlorethylen. Furthermore, it includes the production of acetylene, which is a component in the process of making trichlorethylen. Detailed description ------------------------------ For the production of R134a. INPUTS 1. Hydrogen fluoride - see below. 2. Trichlorethylene - see below. 3. Help chemicals - these have been registered as an input without data from the cradle. OUTPUTS 1. Hydrogen flouride - The flow has not been followed to the cradle. 2. Hydrochloric acid - The flow has not been followed to the cradle. 3. Rest chemicals - The flow has not been followed to the cradle. Energy - Data about energyconsumption for the production of 1 kg of R134a comes from ICI. An assumption has been made that the energy comes from oil and natural gas (50/50), since these are the most common energy carriers in chemical industrial processes. Emissions from incineration of these energy carriers have been included in the activity sheet. Electricity consumption is added in the activity sheet but the environmental load from the production of electricity has not been included. For the production of the first component, hydrogen fluoride. INPUTS 1. Hydrogen gas - general data from literature. 2. Fluoric gas - no data has been found. The gas has been registered as an input without data from the cradle. Energy - data missing. For the production of the second component, trichlorethylene: INPUTS 1. Acetylene - three compounds are needed to produce acetylene, see further down. 2. Chloric gas - general data from literature. OUTPUTS

	1. Hydrogen chloride - general data from literature. The output has not been followed to the grave. Energy - data missing. For the production of acetylen, one of the components in trichlorethylene: INPUTS 1. Natural gas - general data from literature. Half of the gas is used for energy production for the process and half of the gas as a component. 2. Oil - general data from literature. 3. Sulphuric acid - no data has been found. The acid has been registered as an input without data from the cradle. Energy for the production of acetylen: Specific data has not been found, but general data from literature has been used to calculate the energy needed for the processes.

System Boundaries

Nature Boundary	The environmental impact from the system is defined as the natural resources passing over the system borders, and the emissions and waste passing out over the system borders. Production of electricity is not included in the system.
Time Boundary	The data was collected during 1995. Changes in processes will probably occur as time goes by. Landfills are assumed to part of the Technosphere as long as they are used.
Geographical Boundary	The environmental impact caused by the processes and transports in the system are included in the analysis regardless of where around the world they are located. The potential environmental effects included are also included regardless of where around the world they can arise. The final products are assumed to be used in Sweden.
Other Boundaries	For some subsystems data has not been found on production of components. These components are described as not having been followed from the cradle. For the same reason, some emissions and by-products are not accounted for as followed to the grave or cradle. For the production of R134a: Help chemicals - these have been registered as an input without data from the cradle. Hydrogen flouride - the flow has not been followed to the cradle, Hydrochloric acid - the flow has not been followed to the cradle, rest Non defined help chemicals - the flow has not been followed to the cradle. For the production of the first component, hydrogen fluoride: Fluoric gas - no data has been found. The gas has been registered as an input without data from the cradle. For the production of the second component, trichlorethylene: Hydrogen chloride - general data from literature. The output has not been followed to the grave. For the production of acetylen, one of the components in trichlorethylene: Sulphuric acid - no data has been found. The acid has been registered as an input without data from the cradle. The end use, recycling and the use of the product R134a is not included in this system. For information on flows of energy in the different subprocesses, please see ''Function''.
Allocations	By-products are listed, but no impacts are allocated to them. All impacts are allocated to the R134a.
Systems Expansions	Not applicable

About Inventory

Publication	IVF Publication 95832, Llivscykelanalys med arbetsmiljö - en fallstudie av kylfrysar från Electrolux. Delrapport 2: Data (IVF skrift 95833 - Produktion av R134a. ISSN 0349-0653/ISRN IVF - S - 95/832SE -- Data documented by: Caroline Sjöberg, Volvo Technological Developement Corporation; Dept. of Environment and Chemistry. Internal review of documentation by: Dan Wahlström, Volvo Technological Development Corporation, Dept. of Environment and Chemistry Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 5 September 2001 --
Intended User	Companies within the engineeri
General Purpose	Production of R134a is a subprocess in an overall LCA for refrigerators. The overall general purpose of the project was to: * evaluate the possibilities for including occupational health issues in LCAs * to compare the total environmental impact with the occupational health impact from the cradle to the grave for old models of refrigerators compared to new models. * to compare the total impact with respect to environmental issues and occupational healt issues from the cradle to the grave for refrigerators with different cooling agents * to compare the environmental impact with respect tot environment and occupational health issues for the three phases production, use and waste management.
Detailed Purpose	For the production of R134a: the purpose was to analyse the environmental load of an aircondition unit for refrigerators, AC in cars or other industrial applications.

Applicability	This documentation is based on the IVF publication 95833. All data from the report is included in the documentation. According to the IVF publication 95833, the numbers are representive for an average R134a production. According to the IVF publication 95833, individual processes, like the production of R134a, can be used separately from the main processes (production of refrigerators), which here has been done for R134a. The production processes for materials in the subsystems has only been included in some cases, when data has been available.Data comes mainly from literature, and from ICI, and is collected during 1995. The processes for production of R134a have not changed significantly from 1995 to 2000.
About Data	General for the whole study of refrigerators: Consumption of chemical materials and other man-made materials are listed as inflows not followed to the cradle if production of the materials are not included in the study. By-products, for which no benefits have been accounted, are listed as outflows which are not followed to the grave. One of the aims of the study was to find as site-specific data as possible from the suppliers

	to Electrolux. This, however, proved to be impossible since many suppliers refused to communicate these type of data. Instead, the project group focused on mapping out all materials flows and using data from literature. Production of R134a has been estimated from documents, from ICI Norden, Tore Kofstad, March 1995, and McKenzie, personal contact in March 1995. Production of tricloroethylen has been estimated from the ''McKensie, C, ICI UK,'' through a personal contact with the author. Production of acethylene has been estimated from ''Elvers et al. Ullman's encyclopedia of industrial chemistry, fifth complete revised edition, vol A1, page 112'' No comparative studies have been carried out. The data in the report 95833 from IVF is considered to be of good quality by Volvo Technological Development.

SPINE LCI dataset: Production of Copper Anodes

Administrative	
Finished	Y
Date Completed	1998
Copyright	The International Copper Association
Availability	Public

Technical System	
Name	Production of Copper Anodes
Functional Unit	1 kg of anode copper
Functional Unit Explanation	The purity of copper is approximately 99.5% .
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	Data received for this study are based on pyrometallurgical operations only. This activity includes: 1) Copper ore mining; 2) Copper ore concentrate preparation and delivery; 3) Production of matte copper 4) Production of blister copper and 5) Production of copper anodes. Production and use of electricity and fuel used in the processes are included. Below is a description of the included operations. -- 1) Ore mining -- The copper ore mining method used is determined by the size, shape and depth below the

	surface of the ore body. Most copper ores are mined by open pit mining in which large quarries are opened, the ore broken away from the deposits by use of explosives and shovelled into trucks. Actual energy requirements vary widely depending on the characteristics of the mine and ore handling techniques used. The type and the amount of ore deposit and the overlying rock and dirt and the depth of the seam below the surface, affect the level of energy needed for mining the ore. The data for copper mining have been received from three mining companies. The data cover the mining of 45 million tonnes of ore. -- 2) Ore concentrate preparation and delivery -- It is normal practice for mining companies to prepare or concentrate before shipping to reduce the amount of material to be transported. The data mainly relates to transportation of ore concentrate by rail and sea. Transporting the concentrate by sea is extensive. It is assumed that average shipping and rail transport distances were 10 000 km and 500 km respectively. The data covers preparation of 2 million tonnes of concentrate -- 3) Production of matte copper -- Here the ore concentrate, mixed with flux and other additives, is charged in a fuelfired smelting furnace where it is melted. The molten mass is allowed to separate into two layers. The upper slag layer, made up of iron silicate with less than 0,5% of copper, is normally discarded. The lower matte layer, with about 40% to 75% of copper, and containing most of original metal present, is transferred to the converting step to produce blister copper. -- 4) Production of blister copper -- During the production of blister copper the matte is converted to blister in a converter by oxidation in two stages. In the first stage iron sulphide is oxidised and fluxed to form slag which may contain copper (1-5%). The converter slag is ususally recycled back to the smelting furnace. With all the iron removed, the remaining copper sulphide is further oxidised to blister copper. --5) Production of copper anodes -- The blister copper from the converter is transferred to anode furnace to reduce the residual sulphur as well as the oxygen levels in the metal. The data cover the production of 1 million tonnes of copper anodes.

System Boundaries

Nature Boundary	Some of the data on air and water emissions was provided in a form which made it impractical to calculate emissions for unit mass of product output. For example, from an air emission value given in the units of mg/m3 of air, it is not possible to calculate the total emission unless the total volume of air is known and this is seldom measured in pactice. Therefor, where available, only emission values associated with the given amount of product made are used.
Time Boundary	The data comes from mining companies and producers of primary copper for the operations during the 12 month period in 1995 (information why the year 1995 was chosen is not available).
Geographical Boundary	The data comes mainly from European operations. Futher information of the geographical boundaries is not available.
Other Boundaries	The copper producing industry is international. A considerable transport of ore, concentrate and final products are done. The data mainly relates to transportation of ore concentrate by rail and sea. It is assumed that average shipping and rail transport distances were 10 000 km and 500 km respectively.
Allocations	The first thing that has been done to analyse this system is to break down the complex system into a series of separate sub-systems each of which produces a single product but which, when added together, exhibit the same charateristics as the original single system. In this study has co-product allocation and Stoichiometric allocation been applied. It is not often that practical processes exactly match for example the stoichiometric rules and an alternative method using mass must be applied.
Systems Expansions	Not applied

About Inventory

Publication	Ecoprofile of Primary Copper Production- A report for The International Copper Association By Dr. I. Boustead. 1998. -- Data documented by: Sofia Medin, Electrolux ESD Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	LCA practitioners
General Purpose	The purpose of this work was to produce life-cycle inventory data for the production of primary copper and the sub-processes based on data submitted by members of the International Copper Association from their own operations.
Detailed Purpose	The aim is to provide ''cradle to gate'' data for the production of copper anodes, which is a sub-process in the production of primary copper.
Commissioner	- The International Copper Association .
Practitioner	Boustead, Ian Dr - .
Reviewer	
Applicability	There is no recommendation of how to use the data from this report. This activity is part of a ''cradle to gate'' system for primary copper production. In the sequence of operations leading up to primary copper production there are six main stages involved. These are 1) Copper ore mining; 2) Copper ore concentrate preparation and delivery; 3) Production of matte copper; 4) Production of blister copper; 5) Production of copper anodes and 6) Production of primary copper. This activity only covers the stages 1) to 5). All six stages in the primary copper production have been described cumulatively in separate activities in the database.
About Data	Data received from participating companies show sometime wide variation with respect to metal contents of ore and various intermediate products such as concentrates, gas dust and scrap. Therefor has the following assumptions been made: 1. Copper content in ore. Where actual data on copper content of the ore were available these were used. Otherwise the content was calculated on the basis of mass flow. 2. Copper content of matte according to published literature is between 40% to 75%. The assumption made, where the copper content in matte was not derived from mass flow, is therefor 60 %. 3.Average copper content of blister was assumed to be 98,5%, based on published litterature. 4.Average copper content of copper anode was assumed to be 99.5% based om published literature. 5. There is also some loss of copper during ore preperation and the smelting and recovery processes. The loss can be calculated from the mass flow if accurate contents of the input and output materials where known.Where this is not possible, the loss is assumed to be 1% at each step of the sequence of operations. It is further assumed that there is another 4% loss of copper during the operational steps from ore preperation to electro-refining, making the total loss of copper to 5%.
Notes	The results in the report of the Ecoprofile study has been broken down into a number of categories, identifying the type of operation that gives rise to them. The categories are: 1. Fuel production 2. Fuel use 3. Process 4. Transport 5. Biomass (inputs and outputs associated with the use of biological materials such as wood)

Technical System	
Name	Production of dimethylether from energy forest
Functional Unit	1 MJ
Functional Unit Explanation	The amounts in the table show the environmental load per MJ produced dimethylether.
Process Type	Gate to gate
Site	
Sector	Fuel
Owner	
Technical system description	Production of dimethylether using energy forest The wood from the energy forest (Willow) is dried and preheated before it is taken to the gasification. The gasification consists of two different steps, which are partial oxidation and pyrolysis. During the partial oxidation oxygen is added to the bio mass and carbon monoxide is produced. This is an exothermic reaction and therefore it emits heat. This heat is needed for the pyrolysis, during which carbondioxide and hydrogen are produced. The oxygen is separated from the air through distillation. The gas must also be cleansed from other kind of pollutants, because otherwise the methanol catalyst gets inactivated. The cleansed gas is compressed to synthesis-pressure (approximately 60 bar) and is then taken to the methanol-reactor.

System Boundaries	
Nature Boundary	The energy consumption and the emissions to air are accounted for. Also the raw material used is reported in the data.

Applicability	The data is taken from experimental production, and can therefore not be used with success to evaluate the present situation. Testing plants that need not function economically is not to be equalled to commercially producing plants. Because the environmental load is not proportional to the production amount this data should not be used on plants with much greater or smaller production. Data for the willow, which is used in to process can be found in SPINE in the activity ''Production of energy forest''.

SPINE LCI dataset: Production of Dowel Adhesive PVAC 3370

Administrative	
Finished	Y
Date Completed	2000-03-06
Copyright	Casco Products
Availability	Public

Technical System	
Name	Production of Dowel Adhesive PVAC 3370
Functional Unit	1 kg dry dowel adhesive Cascol 3370
Functional Unit Explanation	All emissions, use of resourses and energy consumption is based on 1 kg dry dowel adhesive Cascol 3370 (PVAC 2270). The adhesiver is delivered with 47% dry content. As an average 82 g of package material per kg dry adhesive is delivered.
Process Type	Cradle to gate
Site	Europe
Sector	
Owner	Europe
Technical system description	Dowel Adhesive PVAC 3370 (Cascol 3370) is a formulation of polyvinylacetate, fillers, solvent and additives. The adhesive is produced by Casco Products, Sweden. It is delivered in disposable containers (polyethylene/steel), polyethylene pailts or polypropylene drums. The production of the main raw materials is described below: 1. Natural gas production: The study includes winning, delivery to shore and storage. Natural gas is used in the production of raw materials for polyvinylacetate dispersion and solvent. 2. Crude oil production. The study includes winning, delivery to shore and storage. Crude oil is used in the production ofraw materials for polyvinylacetate dispersion and solvent. 3. There are various processes to produce acetylene and acetic acid, the main raw materials for vinylacetate production. It is not known which processes that are used in this case. 4. Vinylacetate is polymerised to polyvinylacetate with the help of radical forming catalysts. The temperature is often 70-80°C. In this case an emulsion polymerisation in the presence of wetting agent, protective colloides and catalyst is made. 5. Limestone is extracted from the earth, grinded and sieved to fit the specifications for the filler. Extraction an transports are accounted for. 6. Detailes of the process used for the solvent is not known. 7. The PVAc dispersion, filler, solvent and other additives are mixed together in the Casco Decorative Coatings' factory in Kristinehamn, Sweden. Overall information: Transports are included in the system.

System Boundaries	
Nature Boundary	All emissions are considered equivalent, independently of where they take place (locally, regionally, globally , in densly populated areas or rural areas) The emissions presented were chosen as relevant for the product type. Most of the used data are measured, some estimated.
Time Boundary	Most of the process data for the raw materials are valid for 1997, beeing yearly averages where possible. No great changes after that are estimated. The data from Decorative Coatings factory in Kristinehamn are from 1998.
Geographical Boundary	The production of the raw materials is made on different sites in Europe. The mixing of the raw materials is made at Decorative Coatings' factory, Kristinehamn, Sweden.
Other Boundaries	An average of the packages for the product is included in this study. The transportation to the users, use and final desposal of the adhesive is not included. The environmental effects associated with the manufacture of capital equipement and with energy and fuel requirements for plant and buildings conditioning (heat, air, etc) were not included, neither were those associated with personnel requirements.

	Water consumption was not included.
Allocations	Emissions and waste at the Decoraitve Coatings facory in Kristinehamn where the final mixing of teh raw materials is done are allocated on a mass basis among the products that may cause them. Energy required to heat storage buildings, etc is allocated on a mass basis among the products that are stored there.

Applicability	Dowel adhesive Cascol 3370 is suitable for dowel gluing. It should always be used for indoor purposes. For more information about adhesives please contact Casco Products, phone no 46 8 743 4000.
About Data	For the final production of dowel adhesive 3370 all data originates from Decorative Coatings factory in Kristinehamn. For raw materials and auxilary materials suppliers have participated on terms that their data will be treated confidentially. For the production of polyvinylacetate cradle to gate data wer provided, for vinylacetate monomer , filler, solvent and additives cradle to gate data. For fuel data from APME Ecoprofiles are used.. Raw materials used are mentioned under ''Object of study/Functions) Overall information: Transports are included in the system. The fuels for the transports are traced back to the extraction of petrochemical raw materials and the extraction of bio fuels. The electricity data are based on the electricity profiles for each country . For coal, lignite and natural gas data from ETH,Switzerland have been used. For other kinds of energy data from Vattenfall, Sweden have been used. These are combined into energy mixes for different countries according to statistics of 1995 from ''Annual Energy Review 1997'' (European comission) Building of the power plant is not included.

Technical System	
Name	Production of energy forest
Functional Unit	1 MJ
Functional Unit Explanation	The energy content in the produced energy forest (Willow)
Process Type	Gate to gate
Site	
Sector	Forestry
Owner	
Technical system description	Energy forest is the term for fast growing broad-leaf tree, as willow, grey alder, poplar and others. The most common is different kinds of willlow, because it gives a high production, and one can harvest several times before one needs to plant new trees, therefore willow is accounted for here. The whole cycle of growing willow takes 25 years. The cycle includes preparations, planting, six plantations of new trees and finally the process of breaking up the plantation after 25 years. When the trees are planted they are the fertilised with 15 kg/ha phosphorus and 40 kg/ha potassium. The second year, the plantation is fertilised with 45 kg/ha nitrogen, the third year with 125 kg/ha and the fourth year with 95 kg/ha. This information has been gathered through personal conversation with Stig Ledin at the Swedish Institute for Forestry of Deciduous. At the plantation the first, third and sixth year, the plants are fertilised with 60 kg/ha nitrogen. The second year the plantation is fertilised with 100 kg/ha nitrogen. The total energy consumption to prduce the fertilisers used during the 25 year period is 116824 MJ/ha Four litres of Roundup is sprayed on each ha before the planting is done. After the planting there is another pesticide sprayed on the ground, 2,5 litres Gardoprim per ha. The second year the procedure is repeated. The first year, at the plantations 2-6, four litres Roundup are sprayed on each ha, so that the whide disappears. The total amount of energy used to make the pesticides used during the 25 years-period is 4644 MJ/ ha. The production of the energy forest is estimated to be 10 tonnes per ha and year. Because the whole area can not be used the net harvest is 9 tonnes per ha and year. The harvest is done by direct splinting and is calculated to be totally 414000 kg/ha and then contain 50% water. The dry harvest is therefore 207000 kg per ha. After the first year the willow is cut 5400 kg/ha and the first real harvest can be taken the fifth year at approx. 27 000 kg/ha. There after another five harvests can be made every fourth year, at approx. 36 000 kg/ha each. The tractors used are assumed to be diesel driven. The diesel consumption is estimated be 633 litres per ha.

System Boundaries	
Nature Boundary	The boundary has been set at the forest edge, that is all activities run in the forest is accounted. Emissions to air and energy use is accounted for.
Time Boundary	The cycle of growing energy forest is 25 years.
Geographical Boundary	Sweden
Other Boundaries	It is not clear if the pesticides are accounted for. Energy contents in the used fertilisers and diesel are clearly accounted for in the table. Transportations of the wood and supply material, to and from the forest is not accounted for.

Technical System	
Name	Production of ethyl alcohol using energy forest and the CASH-method
Functional Unit	1 MJ
Functional Unit Explanation	The amounts in the table show the environmental load per MJ produced ethanol.

Process Type	Gate to gate
Site	
Sector	Fuel
Owner	
Technical system description	Ethyl alcohol can be produced of several kinds of renewable energy sources. The principle in the making of ethyl alcohol is to transform cellulose or farina in the raw material to fermentable sugar. After the fermentative process the water is removed through distillation and the remaining part is ethyl alcohol with high concentration. In the case studied here the producing plant is of the size 20 000 - 25 000 ton per year. This is considered to be a fairly small amount, which probably is not able to keep a plant in operation in economical terms. The raw material used is energy forest (Willow). The preparation consists of drying and grinding of the biomass, to enlarging the contact surface before the hydrolysis. The difference occurs in the hydrolysis. During the hydrolysis the sugar and lignin are separated. These data concern the CASH-method. In this method the hydrolys is done by adding sulfur dioxide and sulfuric acid. After this process the sugar is fermented into ethyl alcohol, which is separated through distillation. For further information see Von Sievers & Zacchi, 1993, A techno-economical comparison of three processes for the production of ethanol from wood, Kemisk Apparatteknik, LTH, 1993. In the process of making the ethyl alcohol biomass and by-products like methane are used to produce necessary processing steam. The only added source of energy is the energy forest and electricity. In the CASH-process also lignin pellets are produced.

System Boundaries

Nature Boundary	The energy consumption and the emissions to air are accounted for. Also the raw material used is reported in the data.
Time Boundary	The most advanced technology is used in the study.
Geographical Boundary	
Other Boundaries	
Allocations	The by-products are sorted in usable and unusable by-products. The unusable by-products are assumed to be useless, and are the energy use and emissions are allocated to the produced ethyl alcohol. The usable by-products carry their own environmental load.

Reviewer	
Applicability	The data is taken from experimental production, and can therefore not be used with success to evaluate the present situation. Testing plants that need not function economically is not to be equalled to commercially producing plants. Because the environmental load is not proportional to the production amount this data should not be used on plants with much greater or smaller production. Data for the CHAP-method and the Enzyme-method are also available in SPINE. Data for production of the raw material, energy forest, are also available in SPINE.

Technical system description	Ethyl alcohol can be produced of several kinds of renewable energy sources. The principle in the making of ethyl alcohol is to transform cellulose or farina in the raw material to fermentable sugar. After the fermentative process the water is removed through distillation and the remaining part is ethyl alcohol with high concentration. In the case studied here the producing plant is of the size 20 000 - 25 000 ton per year. This is considered to be a fairly small amount, which probably is not able to keep a plant in operation in economical terms. The raw material used is energy forest (Willow). The preparation consists of drying and grinding of the biomass, to enlarging the contact surface before the hydrolysis. The difference occurs in the hydrolysis. During the hydrolysis the sugar and lignin are separated. These data concern the CHAP-method. In this method the hydrolyse is done by adding highly concentrated hydrogen chloride, HCl. After this process the sugar is fermented into ethyl alcohol, which is separated through distillation. For further information Von Sievers & Zacchi, 1993, A techno-economical comparison of three processes for the production of ethanol from wood, Kemisk Apparatteknik, LTH, 1993.

SPINE LCI dataset: Production of extruded aluminium profiles

Administrative	
Finished	Y
Date Completed	2002-05-07
Copyright	EAA
Availability	Public

Technical System	
Name	Production of extruded aluminium profiles
Functional Unit	1000 kg extruded aluminium profile
Functional Unit Explanation	
Process Type	Gate to gate
Site	Not specified. See Geographical boundaries for further information.
Sector	Materials and components
Owner	Not specified. See Geographical boundaries for further information.
Technical system description	The inventory data cover the total semi-fabrication process steps, from extrusion billet production up to packaging before delivery, for the production of aluminium profiles such as those typically used in window or car component manufacture. The internal recycling of process scrap during the extrusion production is included. --- The starting material for the production of rolled aluminium extrusion is an extrusion billet (extrusion ingot). In this documentation the starting material is referred to as ''aluminium ingot'' when it comes from an external primary aluminium or secondary aluminium plant. Rolled aluminium extrusion is also produced by remelting process scrap (Ingot remelting and casting) and this input is referred to as ''casting scrap''. The billet is preheated before extrusion to the required profile. Further processing steps include stretching, sawing and ageing before packaging and shipment to customer. The included process steps are: - Production of semi-finished aluminium - 1. Sawing and scalping 2. Preheating

	3. Extrusion 4. Stretching 5. Sawing 6. Ageing 7. Packaging - Recycling of process scrap - 8. Ingot remelting and casting Production of electricity included in the system. Some further details on the process step Ingot remelting and casting is given below: From the process steps 1 and 3-6, Sawing and scalping , Extrusion, Stretching, Sawing and Ageing scrap is going to the process step Ingot remelting and casting. 268 kg scrap is delivered from Sawing and scalping and 309 kg scrap is delivered from Extrusion, Stretching, Sawing and Ageing. 23 kg casting scrap is recycled within the ingot remelting and casting process.

System Boundaries

Nature Boundary	--- BOUNDARIES VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- Cut-off criteria through out this inventory is basically relevance, as checked by the industry expert team monitoring the work and confirmed by reviewer I. Boustead. As a rough guideline ''less than 1% of total mass'' is applied for the inputs, i.e if the input is less than 1% of the total mass, then it is not included in the inventory table. The base for the choices of included inventory parameters is not further described in the EAA report.
Time Boundary	--- BOUNDARIES VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- The data derived from an industry survey from 1998 and includes literature data from reports dated 1998 and 1999.
Geographical Boundary	--- BOUNDARIES VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- It is not always explicit in the report where the different included process steps take place. Data may be acquired from outside of Europe, e.g. regarding ancillary materials. See litterature references (LitteratureRef) next to the flow table (FlowMetaData) for further information about the data sources for each process step.
Other Boundaries	See Nature boundaries for a specification of the cut-off criteria that has been applied.
Allocations	Allocations are not explicitly specified in the Environmental Profile Report 2000.
Systems Expansions	System expansions are not explicitly specified in the Environmental Profile Report 2000.

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, unspecified
Represents	Not relevant.
Method	PRODUCTION OF SEMI-FINISHED ALUMINIUM The data derive from an industry survey with a coverage ranging from 20% to 70%, depending on the product in question. INGOT REMELTING AND CASTING (RECYCLING OF PROCESS SCRAP) Data were obtained from aluminium-integrated cast house operations, i.e. cast houses associated with semi-finished aluminium production. The 1998 survey on semi-finished aluminium products also encompassed aluminium-integrated cast houses, with 37% coverage for the recycling of process scrap. TRANSPORTS Transport energy and air emission data have been taken from SAEFL Environmental Series 250 (1998) ''BUWAL 250'', table 16.9 ELECTRICITY For all manufacturing operations, the consumption of fossil fuels and emissions linked to electricity production was calculated according to the UCTPE 94 electrical energy model as described in BUWAL 250. Emissions from combustion only, i.e. without the precombustion contribution, have been considered where appropriate in order to make a direct comparision with the corresponding process emissions. Emission data for combustion came from a report prepared by EMPA for EEA (13 December 1997), showing the respective contributions of precombustion and combustion in 'BUWAL 250, table 16.9'. Although emissions from fuel combustion were often covered in the industry survey reporting, data calculated from BUWAL 250 were always used, inview of the fact that the survey results were not sufficiently reliable due to inconsistent use of conversion factors.
Literature Reference	---Rolled sheet production and process scrap recycling Industry survey from 1998 ---Transport energy, electricity, and air emission - SAEFL Environmental Series 250 (1998) ''BUWAL 250'', table 16.9 - EMPA report for EAA dated 27 April 1998, derived from Buwal 250 for national grid systems.

Notes	In this inventory profile it is possible to identify which process step (Extruded profile production, Process scrap recycling) the flow is connected to and if it derives from the energy use, see Note-field for each specific flow. However, in order to get the numerical data devided on these two process steps, see Environmental Profile Report (EAA, 2000).

Notes: This emission derives from the extruded profile production.	Output	Residue	Hazardous waste	1.6			kg	Technosphere	
Notes: The oil is reprocessed or burnt. This residue derives from the extruded profile production.	Output	Residue	Oil	1.7			kg	Technosphere	
Notes: This residue derives both from the extruded profile production.	Output	Residue	Sludge	29			kg	Technosphere	
Notes: This residue derives both from the extruded profile production and the process scrap recycling.	Output	Residue	Solid waste unspecified	23			kg	Technosphere	

About Inventory

Publication	Environmental Profile Report for the European Aluminium Industry, European Aluminium Association, April 2000 -- Data documented by: Maria Erixon, IMI, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, IMI, Chalmers University of Technology Published in SPINE@CPM: 8 May 2002 --
Intended User	LCA-practitioners.
General Purpose	The European Aluminium Association (EAA) aims to contribute to further environmental improvements in aluminium products in a life cycle concept.
Detailed Purpose	The purpose with the Environmental Profile Report 2000 is to provide LCA-practitioners with detailed and up-to-date information representing the aluminium industry activities in Europe. The purposes with formatting the Environmental Profile Report 2000 for the European

	Aluminium Industry to the data documentation format SPINE, according to the data documentation criteria applied at Centre for environmental assessment of Product and Material systems (CPM) are: - CPM and European Aluminium Association (EAA) are anxious to provide life cycle assessment (LCA) practitioners with accurate and up to date environmental data for aluminium production. - EAA is interested in the SPINE formatting procedure and result, as the format is a base for (and therefor somewhat similar to) the new Technical Specification in ISO, ISO 14048, regarding LCA data documentation format. - EAA is interested in the CPM data quality control and documentation criteria.
Commissioner	- EAA (European Aluminium Association) 12 Av. de Broqueville B-1150 Brussels .
Practitioner	- EAA (European Aluminium Association) 12 Av. de Broqueville B-1150 Brussels .
Reviewer	Dr. Ian Boustead, - 2 Black Cottages West Grinstead, Horsham GB-West Sussex RH13 7BD
Applicability	--- SPECIFIC INFORMATION FOR THIS DATA SET --- ENERGY USE IN THE DIFFERENT INCLUDED PROCESS STEPS The energy directly consumed by the operations enclosed within the system bounderies, i.e. in the various production steps, are presented below. See the headline ''DATA SOURCES FOR FUELS/ENERGY PRODUCTION AND COMBUSTION'' in About Data for further information. --- Production of semi-finished aluminium --- Fuel oil (kg) 0,65 Gas (kg) 66 Electricity UCTPE* (kWh) 1142 --- Recycling of process scrap --- Gas (kg) 35 Electricity UCTPE* (kWh) 179 * UCTPE 94 is an electrical energy model for energy supporting all processes in this system (including transports), except electrolysis and cast house. It is described in BUWAL 250, see litterature references. ENERGY CONSUMPTION - INFLUENCE OF ALLOY GRADE AND INGOT HOMOGENEISATION TREATMENT This data set represents an average aluminium alloy. Different alloy types have different energy consumption data; some alloys undergo ingot homogeneisation thermal treatment; hard alloys need more energy for rolling than soft alloys or unalloyed aluminium. In the table below you can find some examples of the variation. The values are presented per 1000 kg rolled aluminium sheet. Alloy groups: I. includes unalloyed aluminium (all 1xxx designations) II. includes alloyed aluminium designated 3xxx, 5xxx (Mg<2,5%), 6xxx and 8xxx III. includes alloyed aluminium designated 2xxx, 5xxx (Mg>2,5%) and 7xxx Electricity consumption (kWh) I II III Overall weighted average non-homogenised 592 642 661 622 homogenised 637 687 706 667 Gas consumption (kg) non-homogenised 79,3 79,6 79,5 79,5 homogenised 94,3 94,6 94,5 94,5 --- GENERAL INFORMATION VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- RECOMMENDATIONS BY EAA WHEN USING THE DATA The data provided by the EAA members for their own process steps are the most up-to-date average data available for these processes, and it is recommended that they be used for LCA purposes. Older literature data should be disregarded, as it may no longer be representative due to technological improvements, progress in operating performance, changes with regard to raw materials or waste treatment, etc. To complete the product system inventory, data - on the production of consumer products, from semi-fabricated aluminium, - on the performance of consumer products in the use phase, and - on the recovery of scrap prior to remelting at the end of the product's useful life should be acquired. EAA recommend that these data be used in LCA studies in accordance with methodologies within the framework of the international standards in the ISO 14040-series.

	RELATED DATA SETS IN SPINE DATA FORMAT The data presented in the Environmental Profile Report is reformatted in to the SPINE format and structured according to the SPINE concept in as many separate activities (sub-systems) as possible. The system scope for the study as a whole is primary aluminium production, semi-finished aluminium production, and recycling. The SPINE formatting resulted in 7 activities. These activities are all published in the SPINE@CPM database. The production and recycling step are intended to be used together. For example, to obtain a cradle to gate-system for rolled aluminium sheet, the activity Primary aluminium production should be connected to the activity Production of rolled aluminium sheet. A recycling step (Aluminium recycling by refiners) could also be connected to such a system, depending on the scope. -- List of activities formatted in the SPINE-format, published in SPINE@CPM -- Primary aluminium production 1. Primary aluminium production Semi-finished aluminium product fabrication 2. Production of rolled aluminium sheet 3. Production of extruded aluminium profiles 4. Production of 0,02-0,2 mm single-rolled aluminium foil 5. Production of 0,005-0,02 mm double-rolled aluminium foil Recycling 6. Re-melting of aluminium scrap 7. Aluminium recycling by refiners Please note: The recycling process 6. Re-melting of aluminium scrap is included in the semi-finished aluminium product fabrication, i.e. activities 2-5. When designing a product system with the activities above where recycled aluminium is regarded, the activity Aluminium recycling by refiners should be used. The Re-melting of aluminium activity is only a specification if the user is specifically interested in this process step. RECYCLING RATES FOR ALUMINIUM PRODUCTS AFTER USE After use, aluminium products are a valuable re-usable resource. The European recycling rates for end products are currently around 95% for the automotive sector and 85% for the building sector. IMPROVEMENTS IN THE ENVIRONMENTAL PERFORMANCE OF ALUMINIUM PRODUCTS AND PROCESSES OVER THE PAST FEW YEARS Over the past few years EAA has achieved major improvements in the environmental performance of its production processes by means of the following: - improvement on existing technology - development and introduction of new technology and operations - increased recycling of all materials in the production process. Examples of major environmental improvements in aluminium products achieved over the past few years include: - weight reduction by downgauging in the packaging sector - energy savings through weight reduction and subsequent fuel reduction in the transport sector - reduction of maintenance in the building sector The previous Ecological Profile Report from EAA was published in 1996.
About Data	--- GENERAL INFORMATION VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- PRECISION According to EAA, the environmental data figures in the inventory table are usually accurate to a precision of 5%. DATA SOURCES FOR FUELS/ENERGY PRODUCTION AND COMBUSTION The electricity supply systems and fuel production and use (transport energy and emission data) have been taken from SAEFL Environmental Series 250 (1998) 'Buwal 250' and EMPA report for EAA dated 27 April 1998, derived from Buwal 250 for national grid systems. All emissions connected with total fuel consumption (i.e. production and combustion of oil, gas or coal) have been taken from SAEFL Environmental Series 250 (1998) 'Buwal 250', table 16.9. Emissions from combustion only, i.e. excluding the contribution of the production of the fuel, have been considered where appropriate in order to make a direct comparision with the corresponding process emissions. Emission data for combustion came from a report prepared by EMPA for EEA (13 December 1997), showing the respective contributions of production and combustion of fuels in 'BUWAL 250, table 16.9'. Although emissions from fuel combustion were often covered in the industry survey reporting, data calculated from BUWAL 250 were always used, in view of the fact that the survey results were not sufficiently reliable due to inconsistent use of conversion factors. REVIEW OUTSPOKE

	Ian Boustead has reviewed and commented on the Environmental Profile Report for the European Aluminium Industry, April 2000, which is a revision of the first Ecological Profile Report from EAA that were published in 1996. Ian Bousteds' review comments on the Environmental Profile Report for the European Aluminium Industry, April 2000: ''...I have received the detailed calculations on which this present environmental report is based. All of the queries that I raised after working through these reports were answered satisfactory.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000 ''Good-quality data were supplied by the EAA member companies, and the number of companies participating provides good coverage of the various processes, meaning that the results can be regarded as representative of the industryas a whole for the production of primary aluminium and subsequent conversion processes.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000 ''Because of the very fragmented nature of the recycling industry and wide variations in practices, it is recognised that the data presented for this sector of the industry can only be regarded as indicative. Nevertheless it is helpful to have such information from an authorative source.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000
Notes	REVIEWER Ian Boustead has reviewed and commented on the Environmental Profile Report for the European Aluminium Industry, which is a revision of the first Ecological Profile Report from EAA that were published in 1996. See AboutData for review comments.

SPINE LCI dataset: Production of guide rings used for spherical roller bearings

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Production of guide rings used for spherical roller bearings
Functional Unit	One guide ring, 9.604kg
Functional Unit Explanation	One spherical roller bearing 232/530 consists of following components: 1. one inner ring 2. one outer ring 3. one guide ring 4. one brass cage 5. 36 rollers (coated or non-coated) The functional unit for this process is one guide ring. The complete name of the guide ring is: RG-232/530 C/243475, and it weighs 9.604 kg. The data can be used (together with data for the other ingoing components) to calculate environmental impact for a complete spherical roller bearing 232/530. Dimensions of the bearing 232/530: di= 530 mm dy= 980 mm breadth= 355 mm The activities for the production of the other ingoing components are also available at SPINE@CPM: * Production of bearing rings * Production of brass cages used for spherical roller bearings * Production of bearing rollers (á 9.2 kg) and the activity for the production of a complete SRB 232/530 can be found as: * Production of SKF Spherical Roller Bearing 232/530
Process Type	Cradle to gate

Site	SKF Mekan ABBox 89 641 21 Katrineholm
Sector	Materials and components
Owner	SKF Mekan ABBox 89 641 21 Katrineholm
Technical system description	The guide ring RG-232/530 C/243475 is manufactured at SKF Mekan AB in Katrineholm, Sweden. A guide ring is used in a spherical roller bearing and its function is to assure that the rollers stay in the raceways of the bearing. The raw material is recycled iron and steel scrap from their own processes and from SKF in Göteborg, but also pig iron produced in Russia. The production of guide rings is very similar to the production of bearing housings at SKF Mekan AB, and much data for the calculations is obtained from an earlier LCA study of the bearing housing SNL 511-609. The following process steps are included in this dataset: 1. Production of pig iron 2. Smelting of iron, type V10 3. Smelt iron in a ladle 4. Heating of smelt iron in a holding furnace 5. Smelt iron in a teaming ladle before casting 6. Casting of iron, type V10 7. Production of quartz sand 8. Cleaning and blastering of cast iron 9. Turning of cast iron rings 10. Phosphatising of cast iron rings In the main treatment there are many different chemicals added. The mineral oil in all of these chemicals is taken into account and followed from the cradle with the activities: ''Extraction of crude oil'' and ''Refining of crude oil''. Each of the process steps 1-10 are further described in separate activities in the SPINE@CPM database. In the dataset following transports are included: A. Transport of pig iron from Riga to Köping (578 km, freighter 2000 - 8000 dwt) B. Transport of pig iron from Köping to Katrineholm (70 km, truck 40/60, Euro 3) B. Transport of steel scrap from SKF Göteborg to Katrineholm (338 km, truck 40/60, Euro 3) C. Transport of quartz sand from Broby to Katrineholm (40 km, truck 40/60, Euro 3) -- 1. Production of pig iron: Pig iron is produced in Russia and is transported with freighter and truck to SKF Mekan AB in Katrineholm. The raw material is iron ore which is smelted in a blast furnace and rolled into billets. Since no information was available from the Russian producer, this dataset refer to production of pig iron at SSAB in Luleå, Sweden. 2. Smelting of iron, type V10 To produce one guide ring 33,75 kg smelted cast iron is needed. The smelt consists of: Pig iron: 3% Steel scrap: 25% Recycled iron: 58% (from their own processes) Steel scrap 14% (from cage manufacturing at SKF Göteborg) Alloying substances are added to give the material the optimal chemical composition. These substances are: Carbomax PK M 1,30% FeMn 0,10% FeS 0,02% Cu 0,07% SiC 1,10% The raw material and the alloying substances are divided into the right proportions according to a specific prescription and are then smelted in the electric furnaces. For the smelting process data from bearing housing was used, but the ingoing components were changed according to the prescription, type V10, which is used specific for guide rings. 3. Smelt iron in a ladle, 4. Heating of smelt iron in a holding furnace, 5. Smelt iron in a teaming ladle before casting: After the smelting process, the smelt is transported in a ladle to the furnace to keep it heated. The smelt is then transported in a teaming ladle to the casting process. The different ladles are preheated through combustion of LPG before use. 6. Casting of iron, type V10: In the casting process the guide rings are formed into a desired shape. A sand form is used, that in this case is a Novaset sand system. The Novaset sand system consists of a forming mass that is self-stiffened [26]: 15,65 kg sand 0,151 kg Novaset 400 0,044 kg Hardener 4030 When the form is rigid it is treated with isopropanol in order to make the surface tight.

	The smelt is then poured into the form and after the smelt has become hard enough, the formed is cracked. The Novaset sand is transported as non hazardous waste to a deposit. 7. Production of quartz sand: The quartz sand used for the sand form in the casting process, come from a sand pit in Broby, Sweden. Digging machines are used in the sand pit, and these are consuming diesel. The sand is dried to lower the moisture content and in the drying process, fuel oil is used. Both production and combustion of diesel and heavy fuel oil are included in this dataset. 8. Cleaning and blastering of cast iron : When the cast iron have been cooled it is cleaned and blastered. It means that remaining material from the casting process (e.g. sand) is removed. This process is identical for bearing housing and guide rings. The casted iron components are cleaned and blastered to get rid of remaining sand and to treat the surface. 9. Turning of cast iron rings: The first step in the final treatment of the guide ring is turning. In this step the ring is turned to its final shape. Iron scrap is returned as raw material and reused in the smelting process. 10. Phosphatising of cast iron rings: When the ring has been turned into its final shape, it is phosphatised. This is done to protect the surface from corrosion by adding rust inhibitors. First the ring is defatted in a highly alkaline bath. Then it is washed and treated in a bath with phosphoric acid. Finally it is treated in an oil-bath with corrosion protective agents and dried. The rings are packed and transported to SKF in Göteborg by truck. The packaging material and the transport by truck from Katrineholm to Göteborg are NOT included in this study.

System Boundaries

Nature Boundary	Recycled iron and steel scrap are not considered as resources and are not followed from the cradle. The nature boundary is the technosphere. Many of the chemicals used in the process are not followed from the cradle, since it was too time consuming and the impact was assumed to be very small since the total amount and the substances according to product data sheets not were considered hazardous. The mineral oil in the different chemicals is taken into consideration though and is followed from the cradle. The steel scrap from the process is not followed to the grave, since it is reused in the process. The steel scrap is considered to be a co-product ending in the technosphere.
Time Boundary	The data was collected during the autumn 2002 and no changes in the procedure are planned for the nearest future.
Geographical Boundary	All activities except for the production of pig iron take place in Sweden. The production of pig iron takes place in Russia.
Other Boundaries	In the dataset following transports are included: A. Transport of pig iron from Riga to Köping (578 km, freighter 2000 - 8000 dwt) B. Transport of pig iron from Köping to Katrineholm (70 km, truck 40/60, Euro 3) B. Transport of steel scrap from SKF Göteborg to Katrineholm (338 km, truck 40/60, Euro 3) C. Transport of quartz sand from Broby to Katrineholm (40 km, truck 40/60, Euro 3) All transports are included in the system, with diesel production (for truck transports) and heavy fuel oil (for freighter from Riga to Köping).. The Electricity production is included for all activities. Swedish average electricity is used for the processes in Sweden, and European average electricity is used for the pig iron production in Russia..
Allocations	Most of the data is allocated according to weight. See each separate activity.
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	02-08-01 - 02-12-31
Data Type	Derived, mixed
Represents	Not relevant.

Method	Data has been gathered from interviews and supplied material from Marja Andersson, SKF Mekan AB, in Katrineholm. She is responsible for environmental questions and much of the data comes from the environmental report from year 2001. SKF Mekan AB has recently published an LCA of Bearing Housing and much data was the same for the guide ring, and could be used directly. See under each separate sub activity for more detailed information.
Literature Reference	Rasmus Beckman and Henrik Olsson; Vilken miljöpåverkan uppstår vid tillverkningen av ett lagerhus?; Master Thesis at Kalmars University; August 2002.
Notes	In this inventory profile it is possible to identify which process step (Extruded profile production, Process scrap recycling) the flow is connected to and if it derives from the energy use, see Note-field for each specific flow. However, in order to get the numerical data devided on these two process steps, see Environmental Profile Report (EAA, 2000).

About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.

Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases. The detailed purpose in the study from where much of the data is obtained, was to calculate the environmental impact from production of a bearing housing.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The data is valid for casted iron products with the same amount of ingoing components (prescription V10) and with the same production process and process equipment as in this study. The data is site specific for SKF Mekan AB in Katrineholm, since the transports from the suppliers are included. The data can be used (together with data for the other ingoing components) to calculate environmental impact for a complete SKF spherical roller bearing 232/530. The activities for the production of the other ingoing components are also available at SPINE@CPM: * Production of bearing rings * Production of brass cages used for spherical roller bearings * Production of bearing rollers (á 9.2 kg) and the activity for the production of a complete SRB 232/530 can be found as: * Production of SKF Spherical Roller Bearing 232/530
About Data	Data is gathered from interviews with Marja Andersson, SKF Mekan AB, Katrineholm. The production of guide rings is very similar to the production of bearing housings at SKF Mekan AB, and much data for the calculations is obtained from an earlier LCA study of the bearing housing SNL 511-609: Rasmus Beckman and Henrik Olsson; Vilken miljöpåverkan uppstår vid tillverkningen av ett lagerhus?; Master Thesis at Kalmars University; August 2002. See each separate activity.
Notes	

SPINE LCI dataset: Production of Hardener 2542 for melamine urea formaldehyde resins 1241 and 1242 production

Administrative	
Finished	Y
Date Completed	2003-03-26
Copyright	Casco Products
Availability	

Technical System	
Name	Production of Hardener 2542 for melamine urea formaldehyde resins 1241 and 1242 production
Functional Unit	1 kg hardener 2542
Functional Unit Explanation	All emissions, use of resourses and energy consumption is based on 1 kg hardener 2545. The hardener is delivered with 70% active substance
Process Type	Cradle to gate
Site	Europe
Sector	
Owner	Europe
Technical system description	Hardener 2542 is a mixture of resorcinol, kaolin, formic acid, thickener and water. Mixing of the raw materials takes place in Akzo Nobel Decorative Coatings plant in Kristinehamn. The hardener is delivered in tank trucks, disposable containers (polyethylene/steel), Fluid bags (polyethylene), Plastic jerrycans (polytethylene) Return containers or Steel drums.

	Packages are not included in the study. The production of the main raw materials is described below: 1. Oil production: The study includes winning, delivery to shore and storage. Oil is used in the production of resorcinol via benzene or propene 2. Resorcinol is deliverd by two different supplier. One uses propen and oxygen in the Hock process. An american manufacturer uses the sulphonation process to produce resorcinol form benzene, oleum , sodium hydroxide and trona. 3. Kaolin is extracted from the earth. Extraction and transports are accounted for. 4. Formic acid is produced from Sulphuric Acid and Sodium formate. Cradle to gate data from the supplier were used. 5. A cellulose derivative is used as thickener. Data for the actual thickener were not available but could be replaced by cradle ot gate data for a similar one. 6. The raw materials, additives and water are mixed at ambient temperatures. Overall information: Transports are included in the system.

System Boundaries

Nature Boundary	All emissions are considered equivalent, independently of where they take place (locally, regionally, globally, in dense populated areas or rural areas) The emissions presented were chosen as relevant for the product type. Most of the used data are measured, some estimated.
Time Boundary	Most of the process data for the raw materials are valid for 1998, beeing yearly averages where possible. No great changes after that are estimated. The data from Decorative Coatings factory in Kristinehamn are from 1999.
Geographical Boundary	The production of the raw materials for resorcinol is made in Japan and the US and the other raw materials on different sites in Europe. The production of Hardener 2542 is made at Decorativ Coatings' factory, Kristinehamn, Sweden.
Other Boundaries	Packages are not included in this study. The transportation to the users, use and final desposal of the hardener is not included. The environmental effects associated with the manufacture of capital equipment and with energy and fuel requirements for plant and buildings conditioning (heat, air, etc) were not included, neither were those associated with personnel requirements. Water consumption was not included. The Japanese resorcinol manufacurer missed data emission and waste data . The american manufacturer seemed to have overestimated raw material use (including emissions and waste resulting form raw materials)
Allocations	Emissions and waste at the Akzo Nobel Decoraitve Coatings plant in Kristinehamn where the hardener is produced are allocated on a mass basis among the products that may cause them. Energy required to heat storage buildings, etc is allocated on a mass basis among the products that are stored there.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	1999
Data Type	Derived, unspecified
Represents	Not relevant.
Method	Accounted as an inventory profile. Data from suppliers and litterature were used. For emission and waste data in our own factory data were taken from environmental report 1999 and Producktion Statistics 1999. Allocations were made on mass basis. For further information see About data.
Literature Reference	For further information see About data.
Notes	In this inventory profile it is possible to identify which process step (Extruded profile production, Process scrap recycling) the flow is connected to and if it derives from the energy use, see Note-field for each specific flow. However, in order to get the numerical data devided on these two process steps, see Environmental Profile Report (EAA, 2000).

About Inventory

Publication	Data documented by: Birgit Nilsson, Casco Products, Sweden Documentation reviewed by: Karolina Flemström, IMI- Industrial environmental informatics, Chalmers University of Technology, Sweden Published in SPINE@CPM: 2003-05-28
Intended User	Users of Melamine-Urea-Formald
General Purpose	
Detailed Purpose	To provide LCI data to producers of load bearing rniture and other wood products where Melamine-Urea-Formaldehyde adhesives 1241 or 1242 with hardener 2542 are used.
Commissioner	- Europe.
Practitioner	Nilsson, Birgit - Casco Products Box 11538, S-10061 Stockholm, Sweden .
Reviewer	
Applicability	Hardener 2542 is used with MUF 1241 or 1242 for the production of load -bearing timber structures and finger joints. It is widely used in the European gluelam industry. The two adhesives mentioned above can be found in the database. More information about adhesives and hardeners can be given by Casco Products, phone no 46 8 743 4000.
About Data	For the production of hardener 2542 all data originates from Akzo Nobel Decorative Coatings plant in Kristinehamn. For raw materials and auxilary materials suppliers have participated on terms that their data will be treated confidentially. Cradle -to -gate data. were provided for all the raw materianls. Data for the thickener were replaced by data for a similar product. Overall information: Transports are included in the system. The fuels for the transports are traced back to the extraction of petrochemical raw materials and the extraction of bio fuels. The electricity

	data are based on the electricity profiles for each country. For coal, lignite and natural gas data from ETH,Switzerland have been used. For other kinds of energy data from Vattenfall, Sweden have been used. These are combined into energy mixes for different countries according to statistics of 1997 from ''Annual Energy Review 1999'' (European comission) Building of the power plant is not included.
Notes	

SPINE LCI dataset: Production of Hardener 2545 for urea formaldehyde resins

Administrative	
Finished	Y
Date Completed	2000-03-10

Availability	Public

Technical System	
Name	Production of Hardener 2545 for urea formaldehyde resins
Functional Unit	1 kg dry hardener 2545
Functional Unit Explanation	All emissions, use of resourses and energy consumption is based on 1 kg dry hardener 2545. The hardener is delivered with 70% dry content. As an average 20.4 g package material per kg dry hardener is delivered.
Process Type	Cradle to gate
Site	Europe
Sector	
Owner	Europe
Technical system description	Hardener 2545 is a mixture of urea, kaolin, inorganic salts, thickener, water and auxilary materials.The hardener is produced by Casco Products, Sweden. It is delivered in tank trucks, disposable containers (polyethylene/steel), Fluid bags (polyethylene), Plastic jerrycans (polytethylene) Return containers or Steel drums. The production of the main raw materials is described below: 1. Natural gas production: The study includes winning, delivery to shore and storage. Natural gas is used in the production of ammonia. 2. Ammonia and urea production: Ammonia is produced from natural gas, air and water in a steam reforming process. In the process carbon dioxide is produced. The urea plant is situated on the same site as the ammonia plant. Urea is produced by reacting ammonia and carbon dioxide at 150 bar at an operation temparature of 185-190°C. The carbon dioxide used in the urea process comes from the ammonia process. Excess carbon dioxide is accounted for as emission to air. 3. Kaolin is extracted from the earth. Extraction an transports are accounted for. 4. Ammonium Chloride is produced by the Solvay process. 5. The raw materials, additives and water are mixed together at Casco Products Decorative Coatings' factory in Kristinehamn, Sweden. Overall information: Transports are included in the system.

System Boundaries	
Nature Boundary	All emissions are considered equivalent, independently of where they take place (locally, regionally, globally , in densly populated areas or rural areas) The emissions presented were chosen as relevant for the product type. Most of the used data are measured, some estimated.

Time Boundary	Most of the process data for the raw materials are valid for 1997, beeing yearly averages where possible. No great changes after that are estimated. The data from Decorative Coatings factory in Kristinehamn are from 1998.
Geographical Boundary	The production of the raw materials natural gas, ammonia, is made on different sites in Europe. The production of Hardener 2545 is made at Decorativ Coatings' factory, Kristinehamn, Sweden.
Other Boundaries	An average of the packages for the product is included in this study. The transportation to the users, use and final desposal of the hardener is not included. The environmental effects associated with the manufacture of capital equipement and with energy and fuel requirements for plant and buildings conditioning (heat, air, etc) were not included, neither were those associated with personnel requirements. Water consumption was not included. For ammonium chloride emissoins from the Solvey plant were not included.
Allocations	Emissions and waste at the Decoraitve Coatings facory in Kristinehamn where the hardener is produced are allocated on a mass basis among the products that may cause them. Energy required to heat storage buildings, etc is allocated on a mass basis among the products that are stored there.

Applicability	Hardener 2545 is used with urea formaldehyde wood adhesives like Cascorit 1206, 1205, 1202 and 1274. It is widely used in the European wood working industry for example for furniture, veneering and so on. It is cured in hot- or high frequency presses. The Wood adhesives mentioned above can be found in the database. Data describing Casco Products hardener 2580 is also available in the database. More information about adhesives and hardeners can be given by Casco Products, phone no 46 8 743 4000.
About Data	For the production of hardener 2545 all data originates from Decorative factory in Kristinehamn. For raw materials and auxilary materials suppliers have participated on terms that their data will be treated confidentially. For urea gate-to gate data wer provided, for kaolinand additives cradle -to -gate data. For ammonia and fuel data from APME Ecoprofiles are used. For ammonium chloride no supplier data wer availible. Instead litterature data (Ullman, p.256) were used. Raw materials used are mentioned under ''Object of study/Functions) Overall information: Transports are included in the system. The fuels for the transports are traced back to the extraction of petrochemical raw materials and the extraction of bio fuels. The electricity data are based on the electricity profiles for each country . For coal, lignite and natural gas data

	from ETH,Switzerland have been used. For other kinds of energy data from Vattenfall, Sweden have been used. These are combined into energy mixes for different countries according to statistics of 1995 from ''Annual Energy Review 1997'' (European comission) Building of the power plant is not included.

Extraction and transports are accounted for. 4. Ammonium Chloride is produced by the Solvay process. 5. Details of the aluminium sulphate process at the supplier are not known. Cradle to gate data was provided by the supplier. 6. The raw materials, additives and water are mixed together at Casco Products Decorative Coatings' factory in Kristinehamn, Sweden. Overall information: Transports are included in the system.

System Boundaries

Nature Boundary	All emissions are considered equivalent, independently of where they take place (locally, regionally, globally , in densly populated areas or rural areas) The emissions presented were chosen as relevant for the product type. Most of the used data are measured, some estimated.
Time Boundary	Most of the process data for the raw materials are valid for 1997, beeing yearly averages where possible. No great changes after that are estimated. The data from Decorative Coatings factory in Kristinehamn are from 1998.
Geographical Boundary	The production of the raw materials natural gas, ammonia, is made on different sites in Europe. The production of Hardener 2580 is made at Decorativ Coatings' factory, Kristinehamn, Sweden.
Other Boundaries	An average of the packages for the product is included in this study. The transportation to the users, use and final desposal of the hardener is not included. The environmental effects associated with the manufacture of capital equipement and with energy and fuel requirements for plant and buildings conditioning (heat, air, etc) were not included, neither were those associated with personnel requirements. Water consumption was not included. For ammonium chloride emissons from the Solvey plant were not included.
Allocations	Emissions and waste at the Decoraitve Coatings facory in Kristinehamn where the hardener is produced are allocated on a mass basis among the products that may cause them. Energy required to heat storage buildings, etc is allocated on a mass basis among the products that are stored there.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, unspecified
Represents	Not relevant.
Method	Accounted as an inventory profile. Data from suppliers and litterature were used. For emission and waste data in our own factory data were taken from Environmental Report 1998 and Production Statistics 1998. Allocations were made on mass basis.
Literature Reference	
Notes	In this inventory profile it is possible to identify which process step (Extruded profile production, Process scrap recycling) the flow is connected to and if it derives from the energy use, see Note-field for each specific flow. However, in order to get the numerical data devided on these two process steps, see Environmental Profile Report (EAA, 2000).

About Inventory

Publication	-- Data documented by: Birgit Nilsson, Casco Products, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden Published in SPINE@CPM: 7 August 2001 --
Intended User	Users of urea formaldehyde woo
General Purpose	
Detailed Purpose	To provide LCI data to producers of flooring, carpentry, furniture and other wood products where urea formaldehyde wood adhesives with hardener 2580 are used.
Commissioner	- Casco Products Box 11538, S-10061 Stockholm, Sweden .
Practitioner	Nilsson, Birgit - Casco Products Box 11538, S-10061 Stockholm, Sweden .
Reviewer	
Applicability	Hardener 2580 is used with urea formaldehyde wood adhesives like Cascorit 1206, 1205, 1202 and 1274. It is widely used in the European wood working industry for example for furniture, veneering and so on. It is cured in hot- or high frequency presses. The wood adhesives mentioned above can also be found in the database. Data describing Casco Products hardener 2545 is also available in the database. More information about adhesives and hardeners can be given by Casco Products, phone no 46 8 743 4000.
About Data	For the production of hardener 2580 all data originates from Decorative factory in Kristinehamn. For raw materials and auxilary materials suppliers have participated on terms that their data will be treated confidentially. For urea gate-to gate data were provided, for kaolin, aluminium sulphate and additives cradle- to- gate data. For ammonia and fuel data from APME Ecoprofiles are used. For ammonium chloride no supplier data were availible.

	Instead litterature data (Ullman, p.256) were used. Raw materials used are mentioned under ''Object of study/Functions) Overall information: Transports are included in the system. The fuels for the transports are traced back to the extraction of petrochemical raw materials and the extraction of bio fuels. The electricity data are based on the electricity profiles for each country . For coal, lignite and natural gas data from ETH,Switzerland have been used. For other kinds of energy data from Vattenfall, Sweden have been used. These are combined into energy mixes for different countries according to statistics of 1995 from ''Annual Energy Review 1997'' (European comission). Building of the power plant is not included.
Notes	

SPINE LCI dataset: Production of high-density polyethylene

Administrative	
Finished	Y
Date Completed	1991
Copyright	
Availability	Public

Technical System	
Name	Production of high-density polyethylene
Functional Unit	1 kg
Functional Unit Explanation	1 kg HDPE.
Process Type	Gate to gate
Site	Neste Polyeten AB Neste Polyeten AB Stenungsund
Sector	Materials and components
Owner	Neste Polyeten AB Neste Polyeten AB Stenungsund
Technical system description	The system consists of production of high-density polyethylene (HDPE). The raw material used is ethylene, which is delivered to the sight via pipeline. HDPE is polymerised in a fluidised bed of catalytic sand at a maximum of 110 deg. Celsius and 21 bar. The polymerisation catalyst (Ziegler-Natta catalyst) consists of metal compounds precipitated in extremely fine quarts sand. The base resin is removed from the reactor in the form of a powder, which is modified by the admixture of additives in an intensive mixer. The melted plastic material from the intensive mixer is converted into a pelletised product in subsequent extrusion and pelletising equipment.

System Boundaries	
Nature Boundary	In the system only emissions to air and water are accounted for at the nature boundary.
Time Boundary	
Geographical Boundary	
Other Boundaries	Raw material, the product and the energy consumption are accounted for.

About Inventory

Publication	Tillman, A-M., H Baumann, E. Eriksson, and T. Rydberg, ''Life Cycle Analysis of Selected Packing Materials. Quantification of Environmental Loadings'' Offprint from SOU 1991:77. Chalmers Industriteknik, Göteborg, Sweden 1992. -- Data documented by: Maria Erixon and Sara Ågren, project employed at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Henrikke Baumann and Anne-Marie Tillman (responsible for the course material) and Ann-Christin Pålsson (resonisble for classification of the dataset), Technical Environmental Planning, Chalmers University of Technology --
Intended User	A Life Cycle Assessment practi
General Purpose	The data set is part of a study about packaging and the environment.
Detailed Purpose	Exercise material in LCA coarse given at Teknisk Miljöplanering at Chalmers University of Technology, Sweden.
Commissioner	
Practitioner	Tillman, Anne-Marie - Technical Environmental Planning Chalmers University of Technology 412 96 Göteborg Sweden.
Reviewer	
Applicability	The data are valid for Swedish conditions at a specific plant, but can be used as an approximation to other countries and other plants. One should though be aware of the fact that the situation in other countries may be very different and depending on this one gets an unreliable result. The data are based on old sources and should therefore not be regarded as information describing the current situation. The emissions caused by the production of the energy used in the system are not accounted for.

SPINE LCI dataset: Production of hot mix for asphalt pavement.

Administrative	
Finished	Y
Date Completed	2001-02-09
Copyright	
Availability	Public

Technical System	
Name	Production of hot mix for asphalt pavement.
Functional Unit	1 kg of hot mix.
Functional Unit Explanation	To get an idea of the order of magnitude of the functional unit, an example is the model of the asphalt pavement studied in the report: 1235 ton of hot mix are used per layer of 1 km road. The road is 13 m wide. 2 layers are needed for the construction of the road. 3 layers will be added during the maintenance operations over 40 years.
Process Type	Cradle to gate
Site	Sweden
Sector	Construction
Owner	Sweden
Technical system description	Production of hot mix. To produce hot mix, bitumen and aggregate are mixed at the asphalt mixing plant, the hot mix process also uses electricity and a fuel (EO oil). An asphalt additive can be added to the mix but is not included in this inventory. The plant is located in Sweden. The bitumen is received from a storage that is supplied by a Swedish refinery but the raw material (crude oil) is from Venezuela. The aggregate is a crushed rock quarried in the vicinity of the asphalt mixing plant. The inventory includes the production of the raw materials (bitumen and aggregate) as well as the production of the fuel (EO oil) in Norway. In general all flows are followed from the cradle (nature). The energy and material resources are traced back to the extraction of natural resources. The production of electricity used in different parts of the system studied have been included. The production of electricity includes operation and maintenance of the power plants and the production of fuel used for the electricity production. National electricity grids has been applied when no spcecific electricity supplier is known. All transports inlude the environmental load from cradle to gate: all inputs are tracked to the cradle, being material or energy.. (for instance the fuel production, cradle to gate is included) The following systems are the most importanat systems included: 1. At the asphalt mixing plant plant: For 1kg of hot mix, the material and energy required at the asphalt mixing plant are as follows: - Wetfix I (adhesion promoter) 240 mg (not included in this inventory) - Bitumen 0,06 kg - Aggregate 0.94 kg - Electricity 0,036 MJ - Heat from EO oil combustion 0,285 MJ Note that 10% of the raw material fed to the process are recovered during maintenance of the asphalt pavement. 90% of the bitumen and aggregate quantities given above are allocated an impact from cradle to the gate while the remaining 10% are considered as material inputs and are not followed from the cradle. 1.1. Heat The emissions due to heat production and the production of fuel for heat is inventoried from cradle to gate. It includes the extraction of the crude oil, the transports and the refining.

1.2. Bitumen
The bitumen inventory includes the extraction of bitumen in Venezuela, the transport by tanker to the refinery, the refining, the transport by ship to the storage, the storing, and the transport by lorry to the asphalt mixing plant. All energy requirements are tracked to the cradle (fuel or electricity).

1.2.1. Extraction of bitumen
The data for extraction in Venezuela are estimated with the help of different litterature references.

1.2.2. Refining
The refining in Nynäshamn is included.

1.2.3. Storage of bitumen
The emissions at the storage and cradle to gate inventory for the fuels used at the storage.

1.3. Aggregate
The aggregate inventory only includes emissions due to the combustion of fuel and the electricity production for the crushing and the transport of aggragate to the asphalt mixing plant by lorry. But this is considered to include most of the environmental load.
For the crushing, the same fuel as at the asphalt mixing plant is used.

2. Transports

2.1. To the refinery
The tanker was approximated by a Swedish model (max. capacity 300 000 ton) using heavy fuel oil with a sulphur content of 2,6%. The loading factor is of around 70% according to the competent personnel at the harbour of Nynäs. The distance between Venezuela and Nynäshamn is approximated to 10 000 km.

2.2. To the storage
A smaller tanker (4 400 ton) is used to model the transport between the refinery and the storage. The distance is 225 nautic miles (416,5 km) and the loading factor of the tanker is assumed to be 50%.

2.3. To the hot mix plant

2.3.1. Recovered material to the hot mix plant
The hot mix milled during maintenance is transported back to the hot mix plant by lorry. 10% of the raw materials for hot mix are recovered from the milled asphalt pavement. The transport of the recovered material is assumed to cover a distance of 50 km.

2.3.2. ''New'' material to the hot mix plant
The quarried and crushed aggregate is assumed to be transported over 5 km by lorry. The bitumen is assumed to cover a distance of 200 km by lorry between the storage and the asphalt mixing plant. Both lorries are 24 ton maximum total weight with a loading factor of 50%.

Over the total cradle to gate inventory, electricity is required, although the electricity input is tracked to the cradle and its impact is included (emissions and natural resource use), it is of interest to inform about the internal flow of electricity. The total electricity requirements are as follows:

Electricity - biomass 6,00e-04 kWh
Electricity - coal 4,55e-04 kWh
Electricity - hydro 9,08e-03 kWh
Electricity - natural gas 1,06e-04 kWh
Electricity - nuclear 8,75e-03 kWh
Electricity - oil 3,73e-05 kWh
Electricity - wind 4,99e-05 kWh

Note that the production of electricity is tracked to the cradle and included in the inventory (as natural resource use, emissions etc.).

For litterature references see: ''About data''

System Boundaries

Nature Boundary	No emissions from the asphalt mixing plant are included since they are not measured. The emissions derived from the heat use is however included. The aggregate inventory only includes emissions due to the combustion of fuel and the electricity production for the crushing and the transport of aggregate to the asphalt mixing plant by lorry. Different environmental impact due to different emissions in different geographical locations have not been taken into accont. All environmental flows of one substance from different locations have been added to one figure.
Time Boundary	Data were obtained between 1992 and 2001. They are applicable for hot mix used in a Swedish road today.

Geographical Boundary	One typical hot mix plant in Sweden (not average) has been studied. For bitumen, all the segments but the extraction are located in Sweden. For the aggregate, all segments are in Sweden Fuels come from Norway. Extraction of crude oil (bitumen) takes place in Venezuela.
Other Boundaries	Recycled material: Note that 10% of the raw material fed to the asphalt mixing plant are recovered during maintenance of the asphalt pavement. No environmental load are included for their production. They are displayed as refined resource input from the technosphere and are not followed from the cradle. Other boundaries: The transport of the different fuels from refinerys to the vehicle or the plant where it is combusted are not included. Environmental influence caused by the production of machines, industrial plants and infrastructure are not included.
Allocations	REFINING Although the crude oil contains 60-65% of bitumen, only 40% of the refinery's impact is allocated to the bitumen. The remaining 60% and the margin of efficiency are allocated to the lighter products of the refinery. This allocation is based on both mass and technological knowledge: the bitumen content in the crude oil is around 65% by mass but the lighter fractions have much higher energy requirements by mass unit for their processing. The lighter fractions also have a higher economical value.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	2001-02-09
Data Type	Derived, unspecified
Represents	Flows to and from nature for a cradle to gate inventory of 1 kg of hot mix asphalt pavement excluding the asphalt additives that are usually used.
Method	Data are from the appendix no. 6 in the litterature reference.
Literature Reference	RIES Adeline - ''Life cycle assessment of an adhesion promoter used in hot mix for asphalt pavement'' - Akzo Nobel / Chalmers University of Technology - 2001.
Notes	For the amount of hot mix required for 1 km of road, refer to the ''Functional unit explenation'' in the technical system.

About Inventory	
Publication	RIES Adeline - ''Life cycle assessment of an adhesion promoter used in hot mix for asphalt pavement'' - Akzo Nobel / Chalmers University of Technology - 2001. -- Data documented by: Adeline Ries, thesis worker at Akzo Nobel Surface Chemistry Internal review at Akzo by: Klas Hallberg, Akzo Nobel Surface Chemistry Documentation review at CPM by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	Akzo Nobel Surface Chemistry.
General Purpose	The purpose is to determine the environmental impact from a hot mix asphalt pavement on an average Swedish countryside road. It is possible to compare its impact with the impact from an adhesion promoter called Wetfix I. Then calculations can show how much the asphalt additive needs to extend the life of the asphalt pavement for the whole system to have a lower environmental load. If the adhesion promoter does not extend the life of the road at all an addition of it will simply increase the environmental load.
Detailed Purpose	To assess the environmental impact of a mass unit of asphalt pavement. To identify the segments of the life cycle that contribute most to the total impact.
Commissioner	- Akzo Nobel Surface Chemistry AB 444 85 Stenungsund Sweden.
Practitioner	Ries, Adeline - 47bis rue Saint Georges F-37210 Rochecorbon France.
Reviewer	Ramnäs, Olle - Chemical Environmental Science Chalmers University of Technology 412 96 Göteborg Sweden
Applicability	Swedish hot mix production with bitumen from Venezuela. Since the transport of crude oil to the refinery is a big contributor to the environmental load, any change of vehicle, the fuel used or the distance would affect the results a lot. Some asphalt mixing plants may not use recovered material or to a different ratio. Since the raw materials are among the main sources of emissions and resource use, the fact that 10% of the raw materials are allocated no impact for in this model is of importance.
About Data	Most electricity used correspond with the Swedish average (electricity grid from 1999 and inventory for each electricity production published in 1997) [Brännström-Norberg et al., 1996], [Brännström, 1998] and [Directorate general for energy, 1999]. For the electricity used in other countries (Norway) respective electricity grids [Directorate general for energy, 1999] are used. Some fuels used are derived from Statoil activities in Norway (North-Sea extraction of crude oil, production of fuel...) [Statoil, 1999] Productions and transport: 1. At the asphalt mixing plant plant - Data are derived from the IVL report [Stripple, 1995] and from sources within Akoz Nobel Surface Chemistry regarding the use of Wetfix I. 1.1. Heat The emissions due to heat production are derived from the IVL report [Stripple, 1995]. The production of fuel for heat is inventoried from cradle to gate using Statoil's environmental report 1999 [Statoil, 1999]. 1.2.1. Extraction of bitumen The data for extraction in Venezuela are estimated. The data are derived from both the IVL study [Stripple, 1995] and the Statoil corresponding data for North-Sea crude oil extraction [Statoil, 1999]. 1.2.2. Refining The inventory is derived from [Stripple, 1995]. The oil used as a fuel at the refinery is estimated by data corresponding to crude oil from North-Sea [Statoil, 1999]. 1.2.3. Storage of bitumen The emissions at the storage and cradle to gate inventory for the fuel used at the storage are derived from the IVL study [Stripple, 1995]. This is the only inventory where the cradle to gate inventory for the fuel is not from Statoil. 1.3. Aggregate The aggregate data are derived from [Stripple, 1995]. 2. Transport data used are for average vehicles [NTM, 2000] The references mentioned above: [Brännström-Norberg et al., 1996]

Notes	The bitumen is inventoried as a natural energy resource use. The use of bitumen in asphalt is indeed making the heat it contains unavailable and the use can be expressed in MJ thus making it possible to compare with other use of energy resources. The publication reports the results of the study of a system which includes the construction of the asphalt pavement and its maintenance over 40 years. In that system, the adhesion improver Wetfix I is used in the hot mix. The person stated as Reviewer were the examiner for the Master of Science thesis.

SPINE LCI dataset: Production of hot rolled steel rings

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Production of hot rolled steel rings
Functional Unit	One ton of hot rolled steel rings
Functional Unit Explanation	The steel rings produced in this study will be further processed into bearing rings and used for SKF spherical roller bearing 232/530.
Process Type	Gate to gate
Site	Ovako Steel AB SE-813 82 Hofors
Sector	Materials and components
Owner	Ovako Steel AB SE-813 82 Hofors
Technical system description	This activity is a subactivity for the whole system activity ''Production of bearing rings'' available in the SPINE@CPM database. When producing the bearing rings the forged steel bars need to be further processed into steel rings at at ring mill . This dataset represents the environmental impact from the making of steel rings from steel bars, 350 mm, at the ring mill at Ovako Steel AB in Hofors, Sweden. The production of the rings takes place at the ring mill (ring mill number 9) at Ovako Steel AB in Hofors, Sweden. The process steps for the inner and outer ring are completely the same, and therefore the process will be described only once. The forged bars (blanks) from Scana Steel AB in Söderfors are cut cold in a Wagner sawing machine and heated in rotating hearth furnaces. The blanks are then upset and pierced in a

	press. The pierced blanks are subject to intermediate heating in a batch furnace before finish rolling in an axial/radial rolling mill. The rings are rolled to a certain profile specific to the demands of SKF. After forging and rolling the rings have their final dimensions. The rings are heat treated to obtain the required material properties and the oxide scale formed during the treatment is then blasted off. The rings are finally checked and packed.

System Boundaries

Nature Boundary	Emission to air and water are included.
Time Boundary	All data refers to year 1999. No changes are planned for the nearest future.
Geographical Boundary	The production of steel rings takes place at the ring mill at Ovako Steel AB in Hofors, Sweden.
Other Boundaries	The production of LPG and Electricity are NOT included in this dataset, but must be followed from the cradle in order to obtain the complete environmental impact of this activity. No internal transport is considered.
Allocations	Allocations have been made according to weight.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	02-08-01 - 02-12-31
Data Type	Derived, mixed
Represents	Flows to and from nature for a cradle to gate inventory of 1 kg of hot mix asphalt pavement excluding the asphalt additives that are usually used.
Method	The data has been gathered from interviews with Eva-Maria Arvidsson at Ovako Steel AB in Hofors. Most data is monitored.
Literature Reference	RIES Adeline - ''Life cycle assessment of an adhesion promoter used in hot mix for asphalt pavement'' - Akzo Nobel / Chalmers University of Technology - 2001.
Notes	For the amount of hot mix required for 1 km of road, refer to the ''Functional unit explenation'' in the technical system.

About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The data are applicable to the production of steel rings from forged steel bars, 350 mm, at the Ring Mill at Ovako Steel in Hofors, Sweden.
About Data	Data is gathered from interviews with Eva-Maria Arvidsson at Ovako Steel AB in Hofors, Sweden.
Notes	

SPINE LCI dataset: Production of hydrogen (cracker) (APME)

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Production of hydrogen (cracker) (APME)
Functional Unit	1 kg hydrogen (from cracker)
Functional Unit Explanation	Typical uses for hydrogen is mainly for hydrogenation reactions, as reducing agent in metals production and as a fuel. Hydrogen (cracker) is one of several products produced in a cracker, among ethylene, propylene and a mixture of butene isomers.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. All flows have been followed to the cradle. However, only the main production process is been described here. The hydrogen is a by-product from the process described below. In this dataset, it is the hydrogen that is of main interest. The output fractions from an oil refinery are complex mixtures of predominantly unreactive saturated hydrocarbons. The first processing step in converting such fractions into feedstock suitable for the petrochemical industries is cracking. Essentially a cracker performs two functions in (a) reducing the complexity of the input mixture into a smaller number of low molecular mass hydricarbons and (b) introducing unsaturation into the hydrocarbons so that they become more reactive. Cracking is a three-stage process. Although it is possible to identifiy schematically the three processes, in practise, they behave as a single unit and information on the process characteristics is usually available only for the overall system. The raw hydrocarbon feed from the refinery is fed to the furnace section where it is raised

	to a high temperature. The reaction products that are formed depend upon the composition of the feed, the temperature of the furnace and the residence time. The cracker operator chooses temperature and residence time to optimise product mix from a given feed. Upon leaving the furnace, the hydrocarbon gas is quench cooled to inhibit further reactions. It is then passed to the separation stage where the individual hydrocarbons are separated from one another by fractional distillation. The principal products from the cracker are ethylene (ethene), propylene (propene) and a mixture of butene isomers. Usually there will be some hydrogen and a number of other hydrocarbons, some of which will be separated, others will be fed back to the furnace and yet others will be used as fuels. Cracker feeds may be naphtha from oil refining or natural gas or a mixture of both. Frequently, other refinery hydrocarbons are also used. When natural gas feeds are used, the primary function of the cracker is to introduce unsaturation into the molecules. For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries	
Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the year 1990-1996. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Data were supplied from 10 hydrogen crackers in OECD countries in Western Europe. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Metholodgy report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Metholodogy report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Results are based on data supplied by 10 hydrogen crackers in OECD countries in Western Europe. Their total production was 810,000 tonnes.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery

	products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

Flow Data

General Activity QMetaData

Date Conceived	1990-1996
Data Type	Derived, mixed
Represents	Flows to and from nature for a cradle to gate inventory of 1 kg of hot mix asphalt pavement excluding the asphalt additives that are usually used.
Method	European average data. Results are based on data supplied by 10 hydrogen crackers in OECD countries in Western Europe. Their total production was 810,000 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstram raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. Data from APMEs website www.lca.apme.org have been downloaded as exe-files. The files are opened and imported into Microsoft Excel. Further, the data from MS Excel is exported to a MS Access database.
Literature Reference	APME - Association of Plastics Manufacturers in Europe, website: http://lca.apme.org
Notes	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature used by CPM (CPM 2000:2). The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New names: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.

Reports are available at APME's web site http://lca.apme.org. -- Documented by Caroline Sjöberg and Sofia Haargaard, Volvo Technological Development Documentation reviewed by: Ann-Christin Pålsson, IMI, Chalmers University of Technology Published in SPINE@CPM: 3 April 2002 --

Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses. 1. Provide APME member companies with information which will highlight potential areas for improving manufacturing processes 2. Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies - Internal company benchmarking - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.

Practitioner	Boustead, Ian - .
Reviewer	Not available -
Applicability	European average data. Results are based on data supplied by 10 hydrogen crackers. Their total production was 810,000 tonnes. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for hydrogen production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data are probably fairly representative for production of hydrogen in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg)

	for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission = 3,67 x {mass fraction of carbon in fuel}/{calorific value in MJ/kg} (kg/MJ fuel).
Notes	The following substance names have been changed from the nomenclature used by APME to adapt to nomenclature according to CPM report 2000:2. Flow Data	
General Activity QMetaData	
Date Conceived	1991
Data Type	Unspecified
Represents	Flows to and from nature for a cradle to gate inventory of 1 kg of hot mix asphalt pavement excluding the asphalt additives that are usually used.
Method	The data are taken from Tillman, A-M., H Baumann, E. Eriksson, and T. Rydberg, ''Life Cycle Analysis of Selected Packing Materials. Quantification of Environmental Loadings'' Offprint from SOU 1991:77. Chalmers Industriteknik, Göteborg, Sweden 1992, where the data is based on both information from Lars Karlsson, Rosenlewen Emballage AB and Chalmers Industripark, Resurs- och avfallssnäla förpackningar, Electrolux-PADD'', 1990, Göteborg.
Literature Reference	Tillman, A-M., H Baumann, E. Eriksson, and T. Rydberg, ''Life Cycle Analysis of Selected Packing Materials. Quantification of Environmental Loadings'' Offprint from SOU 1991:77. Chalmers Industriteknik, Göteborg, Sweden 1992
Notes	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature used by CPM (CPM 2000:2). The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New names: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.

Applicability	The data are valid for Swedish conditions, but can be used as an approximation to other countries. One should though be aware of the fact that the situation in other countries may be very different and depending on this get one gets an unreliable result. The data are based on old sources and should therefore not be regarded as information describing the current situation. There is no raw material going in to the system, which most lightly is the case. The raw material is high-pressure polyethylene. The emissions caused by the production of the electricity used in the system are not accounted for.

SPINE LCI dataset: Production of insulation glass wool

Administrative	
Finished	Y
Date Completed	2002-03-03
Copyright	The declaration does not say if there are any copyrights.
Availability	Public

Technical System	
Name	Production of insulation glass wool
Functional Unit	1 kg glass wool.
Functional Unit Explanation	The functional unit of 1 kg insulation glass wool gives the possibility to compare different suppliers of glass wool insulation.
Process Type	Gate to gate
Site	Sweden
Sector	Manufacturing

Owner	Sweden
Technical system description	The production of glass wool starts with the melting of the raw material, together with additives in a furnace. The excess energy is used for heating the industry. The binding agent is added to the compound at the same time as a spinning machine turns the material into thin threads. In the furnace the binding agent is cured and the glass wool insulation is cold down and cut into the right size.

System Boundaries

Nature Boundary	Emissions to air are included. Emissions to water or soil are not included. What happens after the emissions are released is not included, for example when the emissions react with compounds in the air and affects the environment in another ways.
Time Boundary	The data is from 2002 and as soon as there are any changes the environmental product declaration is updated.
Geographical Boundary	The data is from a Swedish company and everything within the system is in Sweden.
Other Boundaries	The inventory data contains data for production of glass wool and the energy consumption when producing glass wool. Extraction of resources, transportation, use during its lifetime and waste handling are not included. Production of electricity is also not included.
Allocations	The environmental product declaration does not say how the allocation is made when the industry produce more than one product.
Systems Expansions	Not relevant.

About Inventory

Publication	Environmental product declaration, Saint-Gobain Isover, 2002-03-03 -- Data documented by: Annika Olsson, 2002-10-10

	Documentation reviewed by: Karolina Flemström, IMI, Chalmers University of Technology Published in SPINE@CPM: 2002-12-10 --
Intended User	The intended user of this inve
General Purpose	The purpose for an environment product declaration is to inform customers and other interested parties of the impact of the environment for a specific product. Also to give the possibility to compare two different, but similar, products or suppliers.
Detailed Purpose	In this case the specific purpose is to use the inventory data for insulation in a master´s thesis: Life-cycle assessment of two ventilation systems, by Annika Olsson, Chalmers University of Technology, 2002.
Commissioner	Lindab Ventilation AB - .
Practitioner	Olsson, Annika - - .
Reviewer	Bogeskär, Malin -
Applicability	The data are from a specific company producing glass wool and the data is only applicable for this company. The functional unit of 1 kg insulation glass wool may not be the best functional unit if the purpose of a study is to compare two different insulation materials, since it does not say anything about the main function of the insulation. The main function for insulation is the ability to insulate and thermal conductivity describes the material's ability to keep air still in the insulation and to reduce heat radiation. A good functional unit in this case would be the ability to insulate. Thermal conductivity is the most important characteristic for an insulating material. Thermal conductivity describes the material capacity of heat transmission. The rate of the thermal conductivity for an insulating material should be as low as possible. Materials with a low thermal conductivity have a good ability to minimize the convection in the insulation and reduce heat radiation. The conductivity varies between 0.030 and 0.045 W/m°C depending on the structure of the insulation. Thermal conductivity increases with increased temperature. Glass wool has low weight, is resilient and has good resistance to external influence. It is suited for soft insulation products like insulation for spiral ducts and technical insulation for sheets and sheeting.
About Data	The environmental product declaration, this documenation is based on, does not describe any methods for acquire numerical data. They are certified according to ISO 14001. The company follows the regulation from EU and the BYKR (Byggsektorns Kretsloppsråd) the data will be up-dated as soon as there are any changes. The data has been used without any changes of the Environmental product declaration performed by Saint-Gobain Isover.

SPINE LCI dataset: Production of insulation rock wool

Administrative	
Finished	Y
Date Completed	2000-04-01
Copyright	The declaration does not say if there are any copyrights.
Availability	Public

Technical System	
Name	Production of insulation rock wool
Functional Unit	1 kg rock wool.

Functional Unit Explanation	The functional unit of 1 kg insulation rock wool gives the possibility to compare different suppliers of rockwool insulation.
Process Type	Gate to gate
Site	Sweden
Sector	Manufacturing
Owner	Sweden
Technical system description	The production of rock wool starts with the melting of the raw material, together with additives in a furnace. The excess energy is used for heating the industry. The binding agent is added to the compound at the same time as a spinning machine turns the material into thin threads. In the furnace the binding agent is cured and the rockwool insulation is cold down and cut into the right size. The rock wool is for transporting heated or cooled air in a ventilation system, so the mineral wool has a surface of prestressed aluminum foil on one side. The aluminum foil is used to prevent to much heatlosses when the ambient air is cooler than the air in the ducts. The foil is also used to prevent the air from condensate.

System Boundaries

Nature Boundary	The nature boundaries includes the emission to air from the production of rock wool. Emissions to water or soil are not included. What happens after the emissions are released is not included, for example when the emissions react with compounds in the air and affects the environment in another ways.
Time Boundary	The data is from 2000 and there are no known time limitation when using this data.
Geographical Boundary	The data is from a Swedish company and everything within the system is in Sweden.
Other Boundaries	The inventory data contains data for production of rockwool. The stone raw material consist of diabase and lime and the extraction of these resources is included. The extraction and production of the packaging material is included. The electricity consumption for all parts is added together to one number. Extraction of following refined resources: ammonia, formaldehyde, phenol and urea is not included. Transportation, use during its lifetime and waste handling is also not included.
Allocations	The environmental product declaration does not say how the allocation is made when the industry produce more than one product.
Systems Expansions	Not relevant

Commissioner	Lindab Ventilation AB - .
Practitioner	Annika Olsson - .
Reviewer	Bogeskär, Malin -
Applicability	The data are from a specific company producing rockwool and the data is only applicable for this company. The functional unit of 1 kg insulation rock wool may not be the best functional unit if the purpose of a study is to compare two different insulation materials, since it does not say anything about the main function of the insulation. The main function for insulation is the ability to insulate and thermal conductivity describes the material's ability to keep air still in the insulation and to reduce heat radiation. A good functional unit in this case would be the ability to insulate. Thermal conductivity is the most important characteristic for an insulating material. Thermal conductivity describes the material capacity of heat transmission. The rate of the thermal conductivity for an insulating material should be as low as possible. Materials with a low thermal conductivity have a good ability to minimize the convection in the insulation and reduce heat radiation. The thermal conductivity varies between 0.030 and 0.045 W/m°C depending on the structure of the insulation. Thermal conductivity increases with increased temperature. Rock wool is often used when the method of application is high temperature or high demands of fire resistance. Rock wool is also used if there are demands for high compression strength, for example in the ground. When the temperature of the air is below the temperature of the ambient air there is a risk for condensate to occur at the outside of the ducts. To prevent this the ducts must be provided with an insulation that keeps the surface temperature higher than the dew point for the ambient air. For this condensation prevention a steam break is needed. When the temperature of the air is higher than the ambient temperature, it is of great importance to eliminate as much heat losses as possible. For the minimization of heat losses a thermal insulation is needed. For the ability to use hot or cool air in the duct system, mineral wool with a surface of prestressed aluminum foil on one side is needed. The aluminum foil works as a steam break. The thickness of the insulation in this case is set to 100 mm. The thickness is a normal thickness of insulation for ventilation systems and with this thickness the heat losses will be at an acceptable level. The theoretical heat loss for ducts with a diameter of 200 mm, an airflow of 5 m/s and a 20 °C temperature difference between the indoor temperature and

	the ambient air is 0,035 °C per unit of length. With larger diameter and larger insulation thickness the temperature loss will be reduced.
About Data	The environmental product declaration, this documenation is based on, does not describe any methods for acquire numerical data. They are certified according to ISO 14001. Because the company follows the regulation from EU and the BYKR (Byggsektorns Kretsloppsråd) the data will be up-dated as soon as there are any changes. The data has been used without any changes of the Environmental product declaration performed by Paroc AB.

SPINE LCI dataset: Production of iron oxide yellow colorant containing Bermodol SPS 2532

Administrative	
Finished	Y
Date Completed	2004-04-01
Copyright	
Availability	Public

Technical System	
Name	Production of iron oxide yellow colorant containing Bermodol SPS 2532
Functional Unit	1 kg
Functional Unit Explanation	Since the amount of colorant used depend on the specific color the customer wants it's not possible to use ''enough colorant to paint a square meter of wall'' without also specifying a specific shade of iron oxide yellow. Therefore 1 kg is used instead. To give an idea of the magnitude of the Functional unit: A couple of drops of colorant are normally used in a can of paint.
Process Type	Cradle to gate
Site	Sweden
Sector	
Owner	Sweden
Technical system description	The Colorant is produced by mixing polyethylene glycol, iron oxide yellow pigment, water and Bermodol SPS 2532. The plant is located in Sweden. Bermodol SPS 2532 is received from Akzo Nobel in Stenungsund, Sweden. The pigment is produced in Germany. Local water is used and the use of water is assumed to cause no environmental impacts. Polyethylene glycol is produced in the Netherlands. In general all flows are followed from the cradle (nature). The energy and material resources are traced back to the extraction of natural resources. National electricity grids have been used when the specific electricity supplier is unknown. The following are the most important systems included: 1. At the colorant manufacturer For 1kg of colorant these are the material requirements: Pigment 0,54kg Bermodol SPS 2532 0,23kg Water 0,20kg Polyethyleneglycol 0,03kg The production of the colorant is a simple mixing of the ingredients and according to the manufacturer it causes no emissions and uses very little energy. 1.1. PolyethyleneGlycol Since no data could be found for the production of polyethylene glycol in the Netherlands data for the production of polyethylene glycol at Akzo Nobel in Stenungsund, Sweden is used instead.

	1.2. Pigment Since data from the pigment manufacturer in Germany could not be used, cradle to gate data for production of iron oxide in Sweden is used instead. 1.3 Bermodol SPS 2532 The Bermodol SPS 2532 inventory includes cradle to gate data for the raw materials needed and for the steam that is used in the process. All important transports are also included in the inventory. Since the study is cradle to gate, the data in the flow table are the emissions and the resource use needed to manufacture: The colorant, all the raw materials needed to produce the colorant, and so on all the way back to the extraction of natural resources from the cradle (nature). Many of the raw materials (Glycol and Bermodol SPS 2532) are to some extent petrochemical and oil is used both as an energy carrier and as the main component of petrochemical materials. Oil use is accounted for in MJ regardless whether it's used as an energy carrier or not.

System Boundaries

Nature Boundary	No emissions from the colorant manufacturer are included since they are not measured. Different environmental impacts depending on the geographical location of the emission have not been considered. All material flows of the same substance are added together, regardless of where they originate.
Time Boundary	Data is chosen to model the production of colorant in 2003 as accurately as possible.
Geographical Boundary	The production of colorant and Bermodol SPS 2532 is locvated in Sweden The pigment is produced in Germany and the glycol is produced in the Netherlands.
Other Boundaries	Environmental impacts caused by the production of machines, production plants and infrastructure is not included, neither is the environmental impact caused by the employees involved in the manufacture of the colorant and its raw materials. Only emissions and resource use that are considered to be relevant from an environmental point of view are included. Thus the use of air and water as natural resources is not included. Compounds that are emitted or used in small amounts compared to their environmental hazardousness or scarcity are also excluded from the inventory. All major transports are included. Emission data from transports in Sweden is based on simulations conducted by Volvo trucks and Scania in 1997. Transports in Europe is based on supplied values for Euro II engine with ECL-diesel. The emission and resource use data for environmental class 1 diesel has been taken from a life cycle inventory of the vehicle fuels presented by the Swedish transport and communications research board (KFB)
Allocations	Allocations have been done exclusively on mass basis. For example, when emission data from environmental reports, or data that covers the emission from an entire production plant the emissions have been distributed on the total weight of the production of the plant.

About Inventory

Publication	S.Bengtsson, L. Sjöborg, Study of environmental costs and environmental impacts in the chemical industry -- Data documented by:. Stefan Bengtsson, M Sc. student at Chalmers University of Technology and Akzo Nobel. Documentation reviewed by: Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology Published in SPINE@CPM: May 2004
Intended User	Akzo Nobel Surface Chemistry,

General Purpose	The LCA is performed to be used together with a study of environmental costs on the same system, to allow comparisons between environmental costs and environmental impacts in chemical industry.
Detailed Purpose	- Compare environmental impact caused by this colorant with environmental impacts of the colorant that this colorant was developed as an environmentally favourable alternative to - To track down the steps in the lifecycle with the largest environmental impacts
Commissioner	Akzo Nobel Surface Chemistry - .
Practitioner	Stefan Bengtsson and Li Sjöborg Akzo Nobel Surface Chemistry - .
Reviewer	Molander, Sverker, Chalmers University of Technology departm -
Applicability	Swedish production of iron oxide yellow colorants containing nonyl phenol ethoxylates. Since neither pigment nor transports affect the results very much the results could be used for colorants using other pigments produced elsewhere. The largest contribution to the environmental impact is caused by the production of Bermodol SPS 2532. The data should be usable for colorants with similar compositions as the studied colorant.
About Data	All production data have been obtained from technicians or sales managers of the different companies involved. Discussions with technicians have been more extensive for the raw materials produced at Akzo Nobel than for other raw materials. Electricity data is based on the electricity profile of the country in question. (1995 electricity profile). Data for transports in Sweden are average data for long distance transports in Sweden for trucks produced 1995 or later, with catalysts. For transports outside of Sweden average data for older trucks without catalysts is used. A large part of environmental impact data is based on environmental reports.
Notes	

SPINE LCI dataset: Production of iron oxide yellow colorant containing Berol 09

Administrative	
Finished	Y
Date Completed	2004-04-01
Copyright	
Availability	Public

Technical System	
Name	Production of iron oxide yellow colorant containing Berol 09
Functional Unit	1 kg
Functional Unit Explanation	Since the amount of colorant used depend on the specific color the customer wants it's not possible to use ''enough colorant to paint a square meter of wall'' without also specifying a specific shade of iron oxide yellow. Therefore 1 kg is used instead. To give an idea of the magnitude of the Functional unit: A couple of drops of colorant are normally used in a can of paint.
Process Type	Cradle to gate
Site	Sweden
Sector	
Owner	Sweden

Technical system description	Production of colorant. Colorant is produced by mixing monoethylene glycol, iron oxide yellow pigment, water and Berol 09. The plant is located in Sweden. Monoethylene glycol and Berol 09 is received from Akzo Nobel in Stenungsund, Sweden. The pigment is produced in Germany. Local water is used and the use of water is assumed to cause no environmental impacts. In general all flows are followed from the cradle (nature). The energy and material resources are traced back to the extraction of natural resources. National electricity grids have been used when the specific electricity supplier is unknown. The following are the most important systems included: 1. At the colorant manufacturer For 1kg of colorant these are the material requirements: Pigment 0,52kg Monoethylene glycol 0,26kg Water 0,12kg Berol 09 0,08kg The production of the colorant is a simple mixing of the ingredients and according to the manufacturer it causes no emissions and uses very little energy. 1.1. Monoethylene Glycol The monoethylene glycol inventory includes cradle to gate data for the raw materials needed (primarily ethylene oxide) and for the Heat consumed in the processes. All important transports are also included in the inventory 1.2. Pigment Since data from the pigment manufacturer in Germany could not be used, cradle to gate data for production of iron oxide in Sweden is used instead. 1.3 Berol 09 The Berol 09 inventory includes cradle to gate data for the raw materials needed and for the steam that is used in the process. All important transports are also included in the inventory. For one of the main raw materials, nonyl phenol, data from Akzo Nobel's Nonyl Phenol plant in Mölndal, Sweden is used instead of data from the current provider. Since the study is cradle to gate, the data in the flow table are the emissions and the resource use needed to manufacture: The colorant, all the raw materials needed to produce the colorant, and so on all the way back to the extraction of natural resources from the cradle (nature). Many of the raw materials (Glycol and Berol 09) are petrochemical and oil is used both as an energy carrier and as the main component of petrochemical materials. Oil use is accounted for in MJ regardless whether it's used as an energy carrier or not.

System Boundaries

Nature Boundary	No emissions from the colorant manufacturer are included since they are not measured. Different environmental impacts depending on the geographical location of the emission have not been considered. All material flows of the same substance are added together, regardless of where they originate.
Time Boundary	Data is chosen to model the production of colorant in 2003 as accurately as possible except for emission data from the production of nonyl phenol, a raw material of Berol 09, where data from the Akzo Nobel site in Mölndal from 1998 is used instead of data from the current supplier of nonyl phenol.
Geographical Boundary	The production of colorant and most of the raw materials are located in Sweden. The pigment is produced in Germany.
Other Boundaries	Environmental impacts caused by the production of machines, production plants and infrastructure is not included, neither is the environmental impact caused by the employees involved in the manufacture of the colorant and its raw materials. Only emissions and resource use that are considered to be relevant from an environmental point of view are included. Thus the use of air and water as natural resources is not included. Compounds that are emitted or used in small amounts compared to their environmental hazardousness or scarcity are also excluded from the inventory. All major transports are included. Emission data from transports in Sweden is based on simulations conducted by Volvo trucks and Scania in 1997. Transports in Europe is based on supplied values for Euro II engine with ECL-diesel. The emission and resource use data for environmental class 1 diesel has been taken from a life cycle inventory of the vehicle fuels presented by the Swedish transport and communications research board (KFB)

Allocations	Allocations have been done exclusively on mass basis. For example, when emission data from environmental reports, or data that covers the emission from an entire production plant the emissions have been distributed on the total weight of the production of the plant.

Applicability	Swedish production of iron oxide yellow colorants containing nonyl phenol ethoxylates. Since neither pigment nor transports affect the results very much the results could be used for colorants using other pigments produced elsewhere. The largest contribution to the environmental impact is caused by the production of monoethylene glycol. The data should be usable for colorants with similar compositions as the studied colorant.
About Data	All production data have been obtained from technicians or sales managers of the different companies involved. Discussions with technicians have been more extensive for the raw materials produced at Akzo Nobel than for other raw materials. Electricity data is based on the electricity profile of the country in question. (1995 electricity profile). Data for transports in Sweden are average data for long distance transports in Sweden for trucks produced 1995 or later, with catalysts. For transports outside of Sweden average data for older trucks without catalysts is used. A large part of environmental impact data is based on environmental reports.
Notes	The report on environmental impacts and costs in the chemical industry is the result of a thesis project carried out in co-operation with Akzo Nobel Surface Chemistry and Chalmers University of Technology. Sverker Molander who is mentioned as reviewer of the study is the examiner of the final thesis. The final thesis report contains a study of environmental costs caused by the production of two colorants as well as a cradle to gate LCA of the same two colorants of which the colorant dealt with here is one.

SPINE LCI dataset: Production of Iron Powder

Administrative	
Finished	Y
Date Completed	2000-01-24
Copyright	
Availability	Public

Technical System	
Name	Production of Iron Powder
Functional Unit	1028.81 g of produced iron powder (PNC-30), with zink stearate (0.8%) as lubricant.
Functional Unit Explanation	The product name of the powder is PNC-30 and it's produced with the iron sponge process. In the original data set the lubricant, zink stearate, and Ferrophosphorus was not included.The easiest way to include it was simply to add it to the other inputs and then of course include it in the functional unit. This is the reason for the uneven number of grams.
Process Type	Cradle to gate
Site	Höganäs AB 26383 Höganäs Sweden
Sector	Materials and components
Owner	Höganäs AB 26383 Höganäs Sweden
Technical system description	This data set includes raw material aqcuisation, transports and production. The raw materials are: virgin iron, coal (coke), antracite and limestone. Höganäs AB buys the raw material from suppliers and the material is transported to the Höganäs AB plant in Höganäs where the production of the iron powder takes place. More specific data on the raw materials can not be given for secrecy reasons. At the plant in Höganäs the production can be divided in these steps: 1. Iron ore concentrate, Coke, Antracite and lime are dried and screened 2. Packing 3. Reduction -tunnel furnace 4. Emptying 5. Crushing/Grinding 6. Storing 7. Grinding 8. Screening 9. Equalizing 10. Full annealing 11. Crushing/Grinding 12. Screening 13. Equalizing 14. Packing 15. Weighting 16. Mixing -in this step the lubricant is added 17. Screening 18. Equalizing 19. Packing The iron powder is produced through the iron sponge process.

System Boundaries	
Nature Boundary	Main emissions to air and water are considered from cradle to gate.
Time Boundary	The data are based on the production in 1996.
Geographical Boundary	The plant is located in Höganäs, Sweden but it is not specified where the raw material is aqcuisated.
Other Boundaries	Subsystems concearning employees are not included. Resuorces not traced back to the cradle are: - Aluminium - Bricks - Cast Compound - Ceramics - Emulsifying agent - H2SO4 - Lime - Na2SO4

	- Solvey soda - Zink stearate
Allocations	not known
Systems Expansions	not known

About Inventory	
Publication	Master's thesis ''LCA on SKF's Spherical Roller Bearing 24024'' by Åsa Ekdahl, ESA-report 2001:1, Department of Environmental Systems Analysis (ESA), Chalmers University of Technology (ISSN 1400-9560) This report is available for download at ESAs web-site: http://www.esa.chalmers.se --- Data documented by: Åsa Ekdahl, M Sc. student at the dept. of Environmental Systems Analysis, Chalmers University of Technology and SKF Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 5 September 2001 ---
Intended User	The intended users are LCA-pra
General Purpose	The general purpose is use within LCAs.
Detailed Purpose	The data are to be used in the study: ''LCA on SKF's Spherical Roller Bearing 24024''. The aim of the study is to descibe the environmental properties of the bearing as well as identify the processes contributing most to the environmental impact.
Commissioner	Patrik Lindroth - SKF Sverige AB SRB Medium D3s3 415 50 Göteborg .
Practitioner	Katarina Edlund - Höganäs AB 26383 Höganäs Sweden .
Reviewer	
Applicability	The data are applicable to PNC-30 iron powder, with zink stearate as lubricant (0.8%) produced by the iron spunge process.
About Data	The data has been calculated by Katarina Edlund in the software LCAiT and are based on a study performed at Höganäs in -97. Because of secrecy she has agreggated the data from the different processes within the cradle to gate process tree which in turn makes it impossible for me to evaluate the quality of the data.
Notes	Data has been collected and delivered by Katarina Edlund at Höganäs AB.

SPINE LCI dataset: Production of Kraftliner

Administrative	
Finished	Y
Date Completed	2000-01-18

Availability	The database is public and can be ordered from KRAFT Institu

Technical System	
Name	Production of Kraftliner
Functional Unit	One ton of net saleable produced Kraftliner
Functional Unit Explanation	Saleable means ready for delivery to customer.

Process Type	Gate to gate
Site	European average
Sector	Materials and components
Owner	European average
Technical system description	Kraftliner is a component used for manufacturing of corrugated board. The Kraftliner is manufactured in a paper mill. These data are taken from ''European Database for Corrugated Board - Life Cycle Studies'' published by FEFCO, Groupement Ondulé and KRAFT Institute. These are the most resent data and are based on the year 1996. There will be an update in the year 2000 in which the data will be based on 1999. Only the processes within the mill are included. That is no transports to or from the mill are included. The forestry processes are not included. The raw material for Kraftliner is wood, that is virgin fibres. Most of the wood is delivered to the mill in the form of pulpwood logs but a substantial part is brought to the mill as wood chips from saw mills. The pulpwood logs have to be debarked and chipped before further processing. Therefore logs pass through a barking drum and a chipper. The chips are then checked for oversized chips and other unwanted things. The oversized chips go through the chipper ones more. The chips are then stored in a chip pile before processing. The wood chips are cooked to pulp by the kraft cooking process. It is a highly alkaline cooking process with caustic soda and sodium-sulphide as active cooking chemicals. The cooking takes place in a digester at high pressure at a temperature of 150-170 degrees Celcius. The pulp yield is normally around 55% i.e. 1000 kg of dry wood gives 550 kg of pulp. The spent cooking liquor is drained off and washed out of the pulp. It contains wood substances as well as cooking chemicals. The liquor is concentrated and burnt for steam production and recovery of the cooking chemicals. The pulp is defiberized in refiners, screened and washed before being sent to the paper mill. The pulp is mechanical treated in beaters to improve fibre-to-fibre bonding and the strenght of the paper. The pH-level of the pulp slurry is adjusted with acid and some additives are added to facilitate the paper production. Finally the pulp slurry is screened and diluted before being sent to the head box of the paper machine. The paper is formed from the head box onto the wire and dewatered through the wire primarily by the action of gravity and suction.Further dewatering by mechanical means take place in the press section where water is taken out of the sheet by pressing between felts. The final drying takes place in the drying section of the machine where the sheets run against heated cylinders to get its final dryness of 92%. The collected water is reused. Kraftliner is normally a two ply product and therefor requires a paper machine with two head boxes and normally also two wires. The base brown ply contains recycled paper pulp and the internal machine broke pulp in addition to wood fibres from the integrated pulp production. The top ply is normally wood pulp from the integrated pulp production that is more refined and cleaner to give the top surface the right characteristics and printability. After the paper machine there is a slitter winder where the big jumbo reel from the paper machine is rewound and cut down to customer reel formats according to customer orders. Finally the reels are weighted, marked, labelled and prepared for shipment to the customer, the corrugated board industry.

System Boundaries

Nature Boundary	Emissions from fuel combustion outside the mill is not included in the data. Emissions to air from the sites have been reported. Emissions from incineration of rejects with energy recovery at the mill are included. Emissions in the steam of the paper mill are not included. Emissions to air originating from the use of biogas from the mills anaerobic wastewater treatment are included. Water that is taken in has to be treated before it is used in the process, and it is again treated after the process before it is released as effluent to a recipient. The substances in the effluent after wastewater treatment are reported.
Time Boundary	The data are from 1996 and are the most resent ones. In the year 2000 there will be an update of the database which will be based on the year 1999.
Geographical Boundary	The data are valid for production of Kraftliner in Europe, they do not represent a specific plant but are average data from many plants all over Europe. The mills produce 80% of the Kraftliner produced in Europe.
Other Boundaries	The production of raw material and resources is not included. The transportation of raw materials and residues is not included
Allocations	The system is considered as a closed loop system. This is not really true but is seen as a fairly good aproximation and is made in order to avoid allaocations. Within processes allocations has been made according to weight or according to the recipie for making the paper.

About Inventory	
Publication	Published in the report ''European Database for Corrugated Board-Life Cycle Studies'' by FEFCO, Groupement Ondulé and KRAFT Institute in 1997. -- Data documented by: Åsa Ekdahl, M Sc. student at the dept. of Environmental Systems Analysis, Chalmers University of Technology and SKF Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 5 September 2001 --
Intended User	The intended users are practit
General Purpose	The purpose is to provide the industry and its customers the up-to-date knowledge, based on facts concerning the impact of the industry on the environment. Through this database the industry aims to make a contribution to the increasing need for basic environmental data for LCA studies, available in a transparent way.
Detailed Purpose	This data set has been documented for use in the study: ''LCA on SKF's Spherical Roller Bearing 24024''. The aim of the study is to descibe the environmental properties of the bearing as well as identify the processes contributing most to the environmental impact.
Commissioner	KRAFT Institute - Norrtullsgatan 43 S- 113 45 Stockholm .
Practitioner	Manufacurers of Corrugated Board in Europe - .
Reviewer	
Applicability	The data can be used for the production of Kraftliner in Europe that follow the process steps presented under ''Function''. The data are average for plants in Europe and do not represent a specific plant. Data for the production of Semichemical fluting and a Corrugated board box from the ''European Database for Corrugated Board-Life Cycle Studies'' is also available in SPINE@CPM. These activites are named: - Production of Semichemical Fluting - Production of a Corrugated Board Box (182*62*182)
About Data	

Notes	The database will be updated during the year 2000 and will then contain data for the year 1999.

Technical system description	Brief description: Theoretical model for the growth and harvest of rubber in a Malaysian rubber plantation, with transport to Europe and refining of the raw rubber to latex elastics. Process description: The yield of the harvested rubber is set to 1 000 kg rubber/ha and year. The main problem for the rubber production is diseases, since the crop is highly susceptible at all stages of its development. In order to apply the pesticides and insecticides studies have found that the pesticides/insecticides together with a refined oil and a suitable emulsifier gives a good fogging effect. Following fungicides are preferably used: Tridemorph 0.5 kg/ha (against Odium SLF) Chlorothalonil 0.4 kg/ha (against Colletotrichum SLF) Copper Oxychloride 1,2 kg/ha (against Phytophtora Leaf Fall) (SLF = secondary leaf fall) To these formulations was added 20% diesel. The fog generator has a capacity of 100-150 ha/day. The insecticide Permethrin is also used. Amount 0.07 kg/ha (against Hemithea Costipunctata, Euproctis, Hyposidra Talaca, etc) It can be assumed that the main part of the work are made by hand, also to draw off the rubber. In Malaysia this type of production is often a family business, and a normal figure is that one family can handle approx. 5,7 ha rubber trees. The transport is assumed to be 20,000 km by boat, using bunker C oil. The enrgy consumption would be 0.2 MJ/tonkm, or in this case 4MJ/kg rubber. Latex industry: No specific recipe can be used due to confidentiality, so the assumptions for the refining process is only based on the use of rubber in the refining process. The yield from the process is rather bad, so there is a need for 40% more rubber than the result of latex elastics. It is assumed that the emissions connected to the process, except for the energy, are neglectable.

System Boundaries

Nature Boundary	Raw material consumption Energy consumption
Time Boundary	
Geographical Boundary	Malaysian rubber plantation, transport to Europe
Other Boundaries	Only trees that give a yield of rubber are taken into account, the growth from seed to tree is excluded. The rawmaterials for the biocides are not followed to their extraction.
Allocations	No allocations
Systems Expansions	N/A

About Inventory

Publication	Internal report at SCA Mölnlycke: ''The Rubber Model'', G. Brohammer. -- Data documented by: Ellen Riise, Mölnlycke AB Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	LCA practitioners
General Purpose	To be used in LCA studies, when data is missing
Detailed Purpose	
Commissioner	- SCA Mölnlycke AB, 405 03 Göteborg.
Practitioner	Brohammer, Göran - KM Miljöteknik AB, Rullagergatan 6, 415 26 Göteborg.
Reviewer	
Applicability	CERTAIN CAUTIONS: This study is very roughly made but could be seen as better than nothing.
About Data	GENERAL DATA SOURCE DESCRIPTION:
Notes	

SPINE LCI dataset: Production of Linear Alkylbenzene Sulphonates (LAS)

Administrative	
Finished	Y
Date Completed	1995-04-01
Copyright	Carl Hanser Verlag, München
Availability	Public

Technical System	
Name	Production of Linear Alkylbenzene Sulphonates (LAS)
Functional Unit	1000 kg
Functional Unit Explanation	All emissions, use of resources and energy consumption is based on 1000 kg of LAS.
Process Type	Cradle to gate
Site	Europe
Sector	
Owner	Europe
Technical system description	BRIEF DESCRIPTION: The main steps of LAS production are: Crude oil production: The study includes drilling, pumping and separation of crude oil from brine water and tank storage. Crude oil refining: The refining includes desalting, hydrotreating and distillation (fractionation/extraction of crude oil into paraffins, olefins, benzene and ethylene). Benzene production: Benzene is one of the products from crude oil refining. n-Paraffin production: Benzene is one of the products from crude oil refining. Sulphur production: Sulphur is used in the LAS production process. No details were given on sulphur production. Salt mining: Salt is used for the production of caustic soda. No details were given on salt mining. Caustic soda production: Caustic soda is used in the LAS production process. No details were given on the production of caustic soda. LAB production: In the process, linear alcyl benzene (LAB) is produced from benzene and n-paraffins. LAS production: The process includes sulphonisation and neutralisation of LAB from sulphur and caustic soda.. Information concerning all the subsystems described above: Transports are included in the system. The fuels for the transports and the fuels for the processes are traced back to the extraction of petrochemical raw materials and/or the extraction of bio fuels. The electricity data are based on the electricity profile for each country and the petrochemical and biomass raw materials for electricity production are traced back to the extraction process (same process as for fuel raw materials).

System Boundaries

Nature Boundary	All emissions are considered equivalent, independent of where they take place (locally, regionally, globally; in densely populated areas or rural areas).
Time Boundary	The process data used pertain mainly to 1992, being yearly averages where possible. It is recognised that operating processes and conditions are constantly evolving.
Geographical Boundary	This study examined the surfactant production in Europe, notably manufacturing processes conducted in Belgium, France, Germany, Italy, the Netherlands, Spain and the United Kingdom.
Other Boundaries	The detergent formulation, use and final disposal of the surfactants were not covered. The environmental effects associated with the manufacture of capital equipment and with energy and fuel requirements for plant and building conditioning (heat, air etc.) were not included, neither were those associated with personnel requirements. For electricity based on nuclear power and wind power, no emissions and resource exploits have been accounted for.
Allocations	Raw materials, energy and environmental emissions are allocated among co-products on an output weight basis, i.e. on the basis of mass. Co-products in this LCI include those materials that are currently recycled, reused or marketed in some beneficial way.
Systems Expansions	N/A (unless aggregated system from special type of comparative LCI study)

About Inventory

Publication	Tenside Surfactants Detergents 32 (1995) 2 Carl Hanser Verlag, München -- Data documented by: Malin Ericson, Akzo Nobel Surface Chemistry Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	Manufacturers and users of sur
General Purpose	-To produce an authoritative and comprehensive Life Cycle Inventory for major surfactant production in Europe through a common approach in order to facilitate objectivity in surfactant assessments on environmental grounds. -To secure the best possible validation of data and broad acceptance of the methodology and conclusions by industry, regulatory authorities and academia, through assessment of the study by an appropriate expert review panel.
Detailed Purpose	-To establish an industry-wide inventory of the energy and emissions associated with the production of major surfactants in Western Europe under the conditions prevailing in 1992. -To bring together environmental data on the use of the main raw material sources - crude oil, natural gas, mineral, oleochemical, agricultural feedstock - for the processing pathways to the derived major surfactants. -To provide benchmarks for the processing steps of surfactant production against which individual producers can assess their own processes and identify opportunities for improvement. -To publish the results of the study and its conclusions in the open literature for access and reference by interested bodies.
Commissioner	- European LCI Surfactant Study Group (CEFIC/ECOSOL).

Reviewer	Klöppfer, Prof. Dr. W. - C.A.U. Consultants Frankfurt, Germany

Applicability	LAS is an anionic surfactant and a predominant surfactant in commercial detergent preparations. The world LAS production in 1993 was nearly 2 million tonnes. It represents appproximately 1/3 of all the total surfactant production, excluding soap. Since its introduction on the market it has been the predominant surfactant in commercial detergent preparations, such as powders and liquids for textile, dish washing and industrial cleaners, mainly because of its compatibility and synergistic interactions with other ingredients. It is generally not possible to replace one surfactant type by another without changing other components of a preparation, or altering performance characteristics. Therefore, it is not in general meaningful to compare surfactants on a weight basis.
About Data	13 industrial companies participated in the project, including major surfactant manufacturers, raw material and intermediate suppliers, as well as surfactant users in Europe, some of whom are both manufacturers and users. Participating companies are BASF, Colgate-Palmolive, Condea, Enichem Augusta, Henkel, Hoechst, Hüls, ICI, Petresa, Procter & Gamble, Shell, Unilever and Wibarco. Process data were obtained directly from each company performing the process. These data were often proprietary. Therefore, technical process data from private corporations were collected from a minimum of three producers for each intermediate and surfactant type. The information is presented in the form of industry averages in order to preserve confidentiality. Fuel-related data for European countries were based on various governmental statistics and industry contacts (aggregated and provided by Dr. I. Bousted, The Open University, UK).
Notes	Data for other surfactants such as Alcohol sulphates (AS), Alcohol ethoxy sulphates (AES), soap, Secondary alkane sulphonates (SAS), Alcohol ethoxylates (AE) and Alkyl polyglucosides (APG) were given in the same study.

SPINE LCI dataset: Production of linoleum

Administrative	
Finished	Y
Date Completed	1994

Technical System	
Name	Production of linoleum
Functional Unit	1 m2
Functional Unit Explanation	1m2 linoleum.
Process Type	Gate to gate
Site	Forbo plant at Krommenie Amsterdam
Sector	Materials and components
Owner	Forbo plant at Krommenie Amsterdam
Technical system description	Production of Linoleum Linseed oil is catalytically oxidised and polymerised with air in large tanks. This produces linoxyn, which is mixed with resin. The cement is then mixtured with powdered cork, powdered wood, powdered limestone and pigment (titanium dioxide). After the mixing process, a homogeneous linoleum mass is obtained, which is then converted into granules. The granules are fused to backing, made from jute, under pressure and heat. The still soft sheeting is hung up in long loops in drying rooms to mature further, and is left there for two to three weeks. The sheets are coated and the sheeting is trimmed and rolled and after packaging it is ready for sale. The production chain takes four to six weeks. Linoleum wastage (from trimming and similar processes) is recovered to more than 99% in the production process.

SPINE LCI dataset: Production of low-density polyethylene

Administrative	
Finished	Y
Date Completed	1991
Copyright	
Availability	Public

Technical System	
Name	Production of low-density polyethylene
Functional Unit	1 kg
Functional Unit Explanation	1 kg LDPE.

Process Type	Gate to gate
Site	Neste Polyeten AB Neste Polyeten AB Stenungsund
Sector	Materials and components
Owner	Neste Polyeten AB Neste Polyeten AB Stenungsund
Technical system description	The system consists of production of low-density polyethylene (LDPE). The raw material used is ethylene, which is delivered to the site via pipeline. LDPE is polymerised at approx. 2300 bar and 300 deg. Celsius. Since the reaction occurs at such high pressures, there are relatively large diffuse emissions of hydrocarbons. The pressure is maintained by electrical-power driven pumps. The resulting LDPE is transferred to an extruder where pelletisation of the base resin takes place. The base resin is then modified in an intensive mixer, by the admixture of additives. The melted plastic material from the intensive mixer is converted into a pelletised product in subsequent extrusion and pelletising equipment.

Publication	Tillman, A-M., H Baumann, E. Eriksson, and T. Rydberg, ''Life Cycle Analysis of Selected Packing Materials. Quantification of Environmental Loadings'' Offprint from SOU 1991:77. Chalmers Industriteknik, Göteborg, Sweden 1992. -- Data documented by: Maria Erixon and Sara Ågren, project employed at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Henrikke Baumann and Anne-Marie Tillman (responsible for the course material) and Ann-Christin Pålsson (responisble for classification of the dataset), Technical Environmental Planning, Chalmers University of Technology --
Intended User	A Life Cycle Assessment practi
General Purpose	The data set is part of a study concerning packaging and the environment.
Detailed Purpose	Exercise material in LCA coarse given at Teknisk Miljöplanering at Chalmers University of Technology, Sweden.
Commissioner	
Practitioner	Tillman, Anne-Marie - Technical Environmental Planning Chalmers University of Technology 412 96 Göteborg Sweden.
Reviewer	
Applicability	The data are valid for Swedish conditions at a specific plant, but can be used as an approximation to other countries and other plants. One should though be aware of the fact that the situation in other countries may be very different and depending on this one gets an unreliable result. The data are based on old sources and should therefore not be regarded as information describing the current situation. The emissions caused by the production of the energy used in the system are not accounted for.

SPINE LCI dataset: Production of lubricating oil

Administrative	
Finished	Y
Date Completed	1997-03-01
Copyright	
Availability	Public

Technical System	
Name	Production of lubricating oil
Functional Unit	m3
Functional Unit Explanation	1 m3 produced lubricating oil.
Process Type	Gate to gate
Site	BP Smörjmedel AB Skarsvikshamnen 418 34 Göteborg Sweden
Sector	Materials and components
Owner	BP Smörjmedel AB Skarsvikshamnen 418 34 Göteborg Sweden

Technical system description	BP Smörjmedel AB, which belongs to the Preem combine, produces lubricating oil. A storage of basic oils and other additives are part of the production of lubricating oils. The finished products are stored outsidethe aria, except for a small amount, which is stored in tanks within the area. The company does not use products that causes emissions to air. Hot water is used as an energy source.

System Boundaries

Nature Boundary	The company is not obligated to state other emission- or waste substances than the Swedish Environmental Protection law requires.
Time Boundary	The company is obligated to write an Environmental report once every year. Though the legislated limits can be changed only if the activity is changed.
Geographical Boundary	Sweden
Other Boundaries	Waste water, constituting drainage from hygiene and lavatory, is led to the local sewage treatment works. Waste water, constituting water from spillage plates and drainage from cisterns, is led to AB GRAAB Kemi to be cleaned. Surface water, which is not oil contaminated, is led trough a controlling plant, which is joint for the whole Preem combine, to the recipient. Waste from chemicals and lubricating oils is collected and in closed tanks and transported to AB GRAAB Kemi. The hazardous waste constituting waste from solvents and lubricating oils mm is disposed by AB GRAAB Kemi.

About Inventory	
Publication	The environmental report from BP Smörjmedel AB for 1996, The Board of County in Göteborg and Bohus -- Data documented by: Maria Erixson and Sara Ågren, project employed for the database projet at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	To show the environmental load
General Purpose	The purpose of the Environmental report is to be the base for permission trial of activities that is harmful to the environment and further to make shore that the company comply with the decision.
Detailed Purpose	To control that the legislated limits are not exceeded.
Commissioner	- The Environmental Administration in the municipality of Göteborg Box 360 401 25 Göteborg Sweden.
Practitioner	Johansson, Fred - BP Smörjmedel AB Skarsvikshamnen 418 34 Göteborg Sweden.
Reviewer	- The Environmental Administration in the municipality of Göteborg Box 360 401 25 Göteborg Sweden
Applicability	The function of the technical system is not sufficently described. Contact the company to get the necessary details. To get sufficient information about the emissions to water to do a life cycle analyse see the environmental report from Preem Rarrinaderi, Göteborgsterminalen, Göteborgs Hamn AB and Reci Industri AB. The sewage system is the same for all companies at Skarvik and they have joint sewage treatment works. Reci Industri AB takes care of the rest products from the sewage treatment works. The total amount of the waste water from Skarvik (inkl Preem Rarrinaderi, Göteborgsterminalen and Göteborgs Hamn AB), constituting drainage from hygiene and lavatory, is led to the local sewage treatment works, Ryaverket. For more information see the environmental report from Preem Rarrinaderi, Göteborgsterminalen and Göteborgs Hamn AB. Waste water, constituting water from spillage plates and drainage from cisterns, is led through a local oil separater to AB GRAAB Kemi to be cleaned. For more information see the environmental report from Reci Industri AB, which disposes of the waste. For more information about the waste from the oil separater see the environmental report from Preem Rarrinaderi, Göteborgsterminalen and Göteborgs Hamn AB. Surface water, which is not oil contaminated, is led trough a controlling plant before it is let out in the recipient. For more information about the emissions to the recipient see the environmental report from Preem Rarrinaderi, Göteborgsterminalen and Göteborgs Hamn AB. Hot water is used as energy. The hot water is distributed by Göteborgs Hamn AB's furnace plant. The amount is not specified neither in kWh nor m3.

SPINE LCI dataset: Production of mastic

Administrative	
Finished	Y
Date Completed	2000-11-15
Copyright	The declaration does not say if there are any copyrights.
Availability	Public

Technical System

Name	Production of mastic
Functional Unit	1 kg of mastic.
Functional Unit Explanation	Mastic is used for air-tightening of ducts.
Process Type	Gate to gate
Site	Sweden
Sector	Manufacturing
Owner	Sweden
Technical system description	This documention describes production of mastic. Mastic is used for making products airtight.

System Boundaries

Nature Boundary	Emissions to air, water and soil are not included due to lack of data.
Time Boundary	The data was conceived 2000. There are no known time limitations when using this data.
Geographical Boundary	The raw materials are from Europe but the production of mastic is made in Sweden.
Other Boundaries	The extraction of acrylate dispersion is included. The energy demands is not included due to lack of information. Production of following refined resources: Diethyleneglycol dibenzoaten dipropyleneglycol dibenzoate and ethanol is not included.
Allocations	The environmental declaration does not say how the allocation is made when the industry produce more than one product.
Systems Expansions	Not relevant.

Flow Data

General Activity QMetaData

Date Conceived	2000-01-15--2000-11-30
Data Type	Derived, unspecified

About Inventory

Publication	Environmental declaration, Sika Sverige AB, 2000-11-15 -- Data documented by: Annika Olsson, 2002-10-10 Documentation reviewed by: Karolina Flemström, IMI, Chalmers University of Technology Published in SPINE@CPM: 2002-12-10 --
Intended User	The intended user of this inve
General Purpose	The purpose is to inform interested parties the environmental impact of mastic.

Detailed Purpose	In this case the specific purpose is to use the inventory data for mastic in a master´s thesis: Life-cycle assessment of two ventilation systems, by Annika Olsson, Chalmers University of Technology, 2002.
Commissioner	Lindab Ventilation AB - - .
Practitioner	Annika Olsson - .
Reviewer	Malin Bogeskär -
Applicability	This data is from a specific company making mastic. The data is only applicable for this company. Mastic is UV-radiation and ozone resistant.
About Data	The environmental product declaration, this documention is based on, does not describe any methods for acquire numerical data. Certified according to ISO 9001 and 14001. Because the company follows the regulation from EU and the BYKR (Byggsektorns Kretsloppsråd) the data i the environmental declaration will be up-dated as soon as there are any changes. The data in this inventory are taking directly from the Product declaration of mastic performed by Sika Sverige AB.

SPINE LCI dataset: Production of matte copper

Administrative	
Finished	Y
Date Completed	1998
Copyright	The International Copper Association
Availability	Public

Technical System	
Name	Production of matte copper
Functional Unit	1 kg of Matte Copper
Functional Unit Explanation	The copper content of matte according to published literature is between 40-75%.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	Data received for this study are based on pyrometallurgical operations only. This activity includes: 1) Copper ore mining; 2) Copper ore concentrate preparation and delivery; 3) Production of matte copper. Production and use of electricity and fuel used in the processes are included. Below is a description of the included operations. -- 1) Ore mining -- The copper ore mining method used is determined by the size, shape and depth below the surface of the ore body. Most copper ores are mined by open pit mining in which large quarries are opened, the ore broken away from the deposits by use of explosives and shovelled into trucks. Actual energy requirements vary widely depending on the characteristics of the mine and ore handling techniques used. The type and the amount of ore deposit and the overlying rock and dirt and the depth of the seam below the surface, affect the level of energy needed for mining the ore. The data for copper mining have been received from three mining companies. The data

	cover the mining of 45 million tonnes of ore. -- 2) Ore concentrate preparation and delivery -- It is normal practice for mining companies to prepare or concentrate before shipping to reduce the amount of material to be transported. The data mainly relates to transportation of ore concentrate by rail and sea. Transporting the concentrate by sea is exstensive. It is assumed that average shipping and rail transport distances were 10 000 km and 500 km respectively. The data cover preparation of 2 million tonnes of concentrate -- 3) Production of matte copper -- Here the ore concentrate, mixed with flux and other additives, is charged in a fuelfired smelting furnace where it is melted. The molten mass is allowed to separate into two layers. The upper slag layer, made up of iron silicate with less than 0,5% of copper, is normally discarded. The lower matte layer, with about 40% to 75% of copper, and containing most of original metal present, is transferred to the converting step to produce blister copper.

System Boundaries

Nature Boundary	Some of the data on air and water emissions was provided in a form which made it impractical to calculate emissions for unit mass of product output. For example, from an air emission value given in the units of mg/m3 of air, it is not possible to calculate the total emission unless the total volume of air is known and this is seldom measured in pactice.Therefor, where available, only emission values associated with the given amount of product made are used.
Time Boundary	The data comes from mining companies and producers of primary copper for the operations during the 12 month period in 1995 (information why the year 1995 was chosen is not available).
Geographical Boundary	The data comes mainly from European operations. Futher information of the geographical boundaries is not available.
Other Boundaries	The copper producing industry is international.
Allocations	The first thing that has been done to analyse this system is to break down the complex system into a series of separate sub-systems each of which produces a single product but which, when added together, exhibit the same charateristics as the original single system. In this study has co-product allocation and Stoichiometric allocation been applied. It is not often that practical processes exactly match for example the stoichiometric rules and an alternative method using mass must be applied.
Systems Expansions	Not applied

Flow Data

General Activity QMetaData

Date Conceived	1995
Data Type	Derived, unspecified
Represents	Not relevant.
Method	An LCA calculation of matte copper production. The tables that have been used are the tables 43, 45, 46, 47 and 48 in the Eco- profiles of Primary Copper. A report for The International Copper Association, January 1998. For the following subjects has a slightly different name been use here in SPINE compaired from the original tables in the IAC report: In SPINE: In the IAC report: Iron Ore Iron Natural Gas Gas/Condensate NaCl Sodium Chloride HC Hydrocarbons CH4 Methane Cu Cu++/Cu+++ Na Na+ Calcium Ca++ NO3-N NO3- Hazardous waste Regulated chemical

About Inventory

Publication	Ecoprofile of Primary Copper Production- A report for The International Copper Association By Dr. I. Boustead. 1998. -- Data documented by: Sofia Medin, Electrolux ESD Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	LCA practitioners
General Purpose	The purpose of this study was to produce life-cycle inventory data for the production of primary copper and the sub-processes based on data submitted by members of the International Copper Association from their own operations.
Detailed Purpose	The aim is to provide ''cradle to gate'' data for the production of matte copper, which is a sub-process in the production of primary copper.
Commissioner	- The International Copper Association .
Practitioner	Boustead, Ian Dr - .
Reviewer	
Applicability	There is no recommendation of how to use the data from this report. This activity is part of a ''cradle to gate'' system for primary copper production. In the sequence of operations leading up to primary copper production there are six main stages involved. These are 1) Copper ore mining; 2) Copper ore concentrate preparation and delivery; 3) Production of matte copper; 4) Production of blister copper; 5) Production of copper anodes and 6) Production of primary copper. This activity only covers the stages 1) copper ore mining and 2) copper ore concentrate preparation and delivery and 3) Production of matte copper. All six stages in the primary copper production have been described cumulatively in separate activities in the database.
About Data	The data used for electricity and fuel production in the calculations leading to the results reported comes from the reports of International Energy Agency. Data Assumptions: Data received from participating companies show sometime wide variation with respect to metal contents of ore and various intermediate products such as concentrates, gas dust and

	scrap. Therefor has the following assumptions been made: 1. Copper content in ore. Where actual data on copper content of the ore were available these were used. Otherwise the content was calculated on the basis of mass flow. 2. Copper content of matte according to published literature is between 40% to 75%. The assumption made, where the copper content in matte was not derived from mass flow, is therefor 60 %. 3. There is also some loss of copper during ore preperation and the smelting and recovery processes. The loss can be calculated from the mass flow if accurate contents of the input and output materials where known.Where this is not possible, the loss is assumed to be 1% at each step of the sequence of operations. It is further assumed that there is another 4% loss of copper during the operational steps from ore preperation to electro-refining, making the total loss of copper to 5%.
Notes	The results of the Ecoprofile study has been broken down into a number of categories, identifying the type of operation that gives rise to them. The categories are: 1. Fuel production 2. Fuel use 3. Process 4. Transport 5. Biomass (inputs and outputs associated with the use of biological materials such as wood)

SPINE LCI dataset: Production of Melamin-Urea-Formaldehyde resin 1241(MUF 1241), Wood Adhesive

Administrative	
Finished	Y
Date Completed	2003-03-21
Copyright	Casco Products
Availability	

Technical System	
Name	Production of Melamin-Urea-Formaldehyde resin 1241(MUF 1241), Wood Adhesive
Functional Unit	1 kg MUF 1241
Functional Unit Explanation	All emissions, use of resourses and energy consumption is based on 1 kg MUF 1241. The wood adhesive is delivered with 65% dry content. The content of free formaldehyde is 0.6% Abbreviation: MUF= Melamine-Formaldehyde adhesive
Process Type	Cradle to gate
Site	Europe
Sector	
Owner	Europe
Technical system description	MUF 1241 is produced by Casco Products in Kristinehamn. It is a mixture of an UF and a MF resin, celllulose filler, solvent and acrylate copolymer dispersion. Small amounts of sodium hydroxide and formic acid are used for pH adjustments. Additves are silcic acid for tixotrophy and defoamer. All ingredients except the cellulose filler, silicic acid and defoamer could be followed to the cradle. The packages were not included. The production of the UF and MF resins and formaldehyde takes place at the same site in Kristinehamn. Sodium hydroxide is manufactured in Sweden and transported a short distance by truck, while the main raw materials urea, melamine and methanol are produced in different parts of Europe. Urea and methanol are transported by sea as bulk transports and melamine by truck, most of it in Big Bags. The processes use steam which is produced on site from oil and electricty form the net. The main steps of MUF 1241 production are:

	1. Natural gas production: The study includes winning, delivery to shore and storage. Natural gas is used in the production of methanol and ammonia. 2. Methanol production: Natural gas is produced into synthesis gas in reformers. Synthesis gas is converted to raw methanol in a catalytic process and distilled into finished methanol. Storage is included. 3. Formalin production: Formalin is produced from methanol by oxidation in the Formox process. The process is exothermic and produces steam, which is utilised in the plant. 4. Ammonia and urea production: Ammonia is produced from natural gas, air and water in a steam reforming process. In the process carbon dioxide is produced. The urea plant is situated on the same site as the ammonia plant. Urea is produced by reacting ammonia and carbon dioxide at 150 bar at an operation temparature of 185-190°C. The carbon dioxide used in the urea process comes from the ammonia process. Excess carbon dioxide is accounted for as emission to air. 4. Formic acid is produced from sodium formate and sulphuric acid with sodium sulphate as a by-product. 5. Sodium hydroxide is produced from soduim chloride in an electrolytic reaction. 6. UF resin production: In a condensation reaction UF resin is produced from urea and formalin at temperatures 50-100°C with very small amounts of formic acid and sodium hydroxide to control pH during reaction. Vacuum distillation to 65% dry content of the UF resin is included. 7. The MF resin is produced form formalin and melamine and a modifyer in a condensation reaction with sodium hydroxide to control pH. Vacuum distillation to 65% dry content of the MF resin was included. Inventory data for the modifyer were not available but was replaced by melamine data. 8. All ingredients are mixed at room temperature and the adhesive is made tixotropic by ultra-sound. It is pumped to a storage tank from where it is delivered on tank trucks, containers or steel drums. MUF 1241 is an adhesive which is used in the production of load-bearing timber structures, finger joints and blockboards where there is a demand for light coloured bond lines with high weather and water resistance. It can be used for cold pressing and high frequency pressing. There are different qualities of MUF adhesives which may have differences in open time, pressing time and after curing time. MUF resins ar not normally used for large, curved beams, where instead PRF adhesives are common. Overall information: All transports are included in the system. Abbreviations: MUF=Melamine-Urea-Formaldehyde resin UF= Urea-Formaldehyde resin MF= Melamine-Formaldehyde resin PRF=Phenol-Resorcinol-Formaldehyde resin

System Boundaries	
Nature Boundary	All emissions are considered equivalent, independently of where they take place (locally, regionally, globally, in dense populated areas or rural areas) The emissions presented were chosen as relevant for the product type. Most of the used data are measured, some estimated.
Time Boundary	Most of the process data for the raw materials are valid for 1998, beeing yearly averages where possible. No great changes after that are estimated. The data from Casco Products plant in Kristinehamn are from 1999.
Geographical Boundary	The production of the raw materials natural gas, ammonia, methanol and urea is made on different sites in Europe. The production of formalin, melamin formaldehyde resin and urea-formaldehyde resin is made at Casco Products' plant, Kristinehamn, Sweden.
Other Boundaries	The packages for the product are not included in this study. Transports of materials to the production site in Kristinehamn as well as upstreams transports are included. The transportation to the users, use and final disposal of the glue is not included. The environmental effects associated with the manufacture of capital equipement and with energy and fuel requirements for plant and buildings conditioning (heat, air, etc) were not included, neither were those associated with personnel requirements. Water consumption was not included.

Allocations	Emissions and waste at the Kristinehamn factory where the formalin and resin is produced are allocated on a mass basis among the products that may cause them. Energy required to heat storage buildings, etc is allocated on a mass basis among the products that are stored there. The steam generated in the formaldehyde process is used elsewhere in the factory. The energy produced is credited the formaldehyde.(See system expansion)
Systems Expansions	The production of formalin from methanol is an exothermic process.The heat produced is used for production of steam, which is utilised in other processes or for heating purposes. This steam replaces steam from oil that would otherwise have been needed. Therefore the steam produced in the process has been credited the formalin, i.e. oil consumption and emisssions were reduced. The amount of oil for production of steam on site and emissions from the boiler is known. (See Product Specific Requirements for Certified EPD for chemical products, www.environdec.com)

About Inventory	
Publication	------------------- Data documented by: Birgit Nilsson, Casco Products, Sweden. Documentation reviewed by: Karolina Flemström, IMI - Industrial environmental infomatics, Chalmers University of Technology, Sweden. Published in SPINE@CPM: 2003-05-28
Intended User	Users of Wood Adhesive Casco
General Purpose	
Detailed Purpose	To provide LCI data to producers of gluelam where MUF 1241 is used as an adhesive.
Commissioner	- Europe.
Practitioner	Nilsson, Birgit - Casco Products Box 11538, S-10061 Stockholm, Sweden .
Reviewer	

Applicability	MUF 1241 is a wood adhesive for laminated beams, which gives a light coloured joint. It is always used with hardener 2542. All adhesives for bonding of gluelam must have an approval from an independent institute to be allowed to use in the production of load-bearing timber structures and finger joints. MUF 1241 is approved for the production of load-bearing structures by NTI, Norway, Otto-Graf Institute (FMPA), Germany and SKH/KOMO, Holland. For more product data call Casco Products, +46 8 743 4000.
About Data	For the production of formaldehyde, UF and MF and all data originates from Casco Products' factory in Kristinehamn. For raw materials suppliers have participated on terms that their data will be treated confidentially. For urea and formic acid gate- to- gate data were provided, for methanol and sodium hydroxide cradle -to gate. For ammonia and fuel data from APME Ecoprofiles are used. Raw materials used are mentioned under ''Object of study/Functions) Overall information: Transports are included in the system. The fuels for the transports are traced back to the extraction of petrochemical raw materials and the extraction of bio fuels. The electricity data are based on the electricity profiles for each country . For coal, lignite and natural gas data from ETH,Switzerland have been used. For other kinds of energy data from Vattenfall, Sweden have been used. These are combined into energy mixes for different countries according to statistics of 1997 from ''Annual Energy Review 1999'' (European comission) Building of the power plant is not included. Abbreviations: MUF= Melamine-Urea-Formaldehyde adhesive APME= Association of Plastics Manufacures NTI= Norsk Treteknisk Institut

Technical System	
Name	Production of Melamin-Urea-Formaldehyde resin 1242(MUF 1242), Wood Adhesive
Functional Unit	1 kg MUF 1242
Functional Unit Explanation	All emissions, use of resourses and energy consumption is based on 1 kg MUF 1242. The wood adhesive is delivered with 65% dry content. The content of free formaldehyde is 0.6% Abbreviation: MUF= Melamine-Formaldehyde adhesive
Process Type	Cradle to gate
Site	Europe
Sector	
Owner	Europe
Technical system description	MUF 1242 is produced by Casco Products in Kristinehamn. It is a mixture of an UF and a MF resin, celllulose filler, solvent and acrylate copolymer dispersion. Small amounts of sodium hydroxide and formic acid are used for pH adjustments. Additves are silcic acid for thixotrophy and defoamer. All ingredients except the celluolse filler, silicic acid and defoamer could be followed to the cradle. Packages are not included. The production of the UF and MF resins and formaldehyde takes place at the same site in Kristinehamn. Sodium hydroxide is manufactured in Sweden and transported a short distance by truck, while the main raw materials urea, melamine and methanol are produced in different parts of Europe. Urea and methanol are transported by sea as bulk transports and melamine by truck, most of it in Big Bags.

	The processes use steam which is produced on site from oil and electricty form the net. The main steps of MUF 1242 production are: 1. Natural gas production: The study includes winning, delivery to shore and storage. Natural gas is used in the production of methanol and ammonia. 2. Methanol production: Natural gas is produced into synthesis gas in reformers. Synthesis gas is converted to raw methanol in a catalytic process and distilled into finished methanol. Storage is included. 3. Formalin production: Formalin is produced from methanol by oxidation in the Formox process. The process is exothermic and produces steam, which is utilised in the plant. 4. Ammonia and urea production: Ammonia is produced from natural gas, air and water in a steam reforming process. In the process carbon dioxide is produced. The urea plant is situated on the same site as the ammonia plant. Urea is produced by reacting ammonia and carbon dioxide at 150 bar at an operation temparature of 185-190°C. The carbon dioxide used in the urea process comes from the ammonia process. Excess carbon dioxide is accounted for as emission to air. 4. Formic acid is produced from sodium formate and sulphuric acid with sodium sulphate as a by-product. 5. Sodium hydroxide is produced from soduim chloride in an electrolytic reaction. 6. UF resin production: In a condensation reaction UF resin is produced from urea and formalin at temperatures 50-100°C with very small amounts of formic acid and sodium hydroxide to control pH during reaction. Vacuum distillation to 65% dry content of the UF resin is included. 7. The MF resin is produced form formalin and melamine in the presence of methanol to ethrify the resin in a condensation reaction with sodium hydroxide to control pH. Vacuum distillation to 65% dry content of the MF resin was included. . 8. All ingredients are mixed at room temperature and the adhesive is made tixotropic by ultra-sound. It is pumped to a storage tank from where it is delivered on tank trucks, containers or steel drums. MUF 1242 is an adhesive which is used in the production of load-bearing timber structures, finger joints and blockboards where there is a demand for light coloured bond lines with high weather and water resistance. It can be used for cold pressing and high frequency pressing. There are different qualities of MUF adhesives which may have differences in open time, pressing time and after curing time. MUF resins ar not normally used for large, curved beams, where instead PRF adhesives are common. Overall information: All transports are included in the system. Abbreviations: MUF= Melamine-Urea-Formaldehyde resin UF= Urea-formaldehyde resin MF= Melamine-Formaldehyde reins PRF=Phenol-Resorcinol-Formaldehyde resin

System Boundaries

Nature Boundary	All emissions are considered equivalent, independently of where they take place (locally, regionally, globally, in dense populated areas or rural areas) The emissions presented were chosen as relevant for the product type. Most of the used data are measured, some estimated.
Time Boundary	Most of the process data for the raw materials are valid for 1998, beeing yearly averages where possible. No great changes after that are estimated. The data from Casco Products plant in Kristinehamn are from 1999.
Geographical Boundary	The production of the raw materials natural gas, ammonia, methanol and urea is made on different sites in Europe. The production of formalin, melamin formaldehyde resin and urea-formaldehyde resin is made at Casco Products' plant, Kristinehamn, Sweden.
Other Boundaries	The packages for the product are not included in this study. Transports of materials to the production site in Kristinehamn as well as upstreams transports are included. The transportation to the users, use and final disposal of the glue is not included. The environmental effects associated with the manufacture of capital equipement and with energy and fuel requirements for plant and buildings conditioning (heat, air, etc) were not included, neither were those associated with personnel requirements. Water consumption was not included.

Allocations	Emissions and waste at the Kristinehamn factory where the formalin and resin is produced are allocated on a mass basis among the products that may cause them. Energy required to heat storage buildings, etc is allocated on a mass basis among the products that are stored there. The steam generated in the formaldehyde process is used elsewhere in the factory. The energy produced is credited the formaldehyde.(See system expansion)
Systems Expansions	The production of formalin from methanol is an exothermic process.The heat produced is used for production of steam, which is utilised in other processes or for heating purposes. This steam replaces steam from oil that would otherwise have been needed. Therefore the steam produced in the process has been credited the formalin, i.e. oil consumption and emisssions were reduced. The amount of oil for production of steam on site and emissions from the boiler is known. (See Product Specific Requirements for Certified EPD for chemical products, www.environdec.com)

Technical System	
Name	Production of methanol using energy forest
Functional Unit	1 MJ
Functional Unit Explanation	The amounts in the table show the environmental load per MJ produced methanol.
Process Type	Gate to gate
Site	
Sector	Fuel
Owner	
Technical system description	Production of methanol using energy forest The wood from the energy forest (Willow) is dried and preheated before it is taken to the gasification. The gasification consists of two different steps, which are partial oxidation and

	pyrolysis. During the partial oxidation oxygen is added to the biomass and carbon monoxide is produced. This is an ectoderm reaction and therefore is emits heat. This heat is needed for the pyrolysis, during which carbondioxide and hydrogen are produced. The oxygen is separated from the air through distillation. The gas must also be cleansed from other kind of pollutants, because otherwise the methanol catalyst gets inactivated. The cleansed gas is compressed to synthesis-pressure (approximately 60 bar) and is then taken to the methanol-reactor.

Intended User	Persons or companies intereste
General Purpose	
Detailed Purpose	The data are part of a study concerning alternative fuels
Commissioner	- KFB Komunikations Forsknings Beredningen Box 5706 Linnégatan 2 114 87 Stockholm Sweden.

Practitioner	Blinge Magnus, Arnäs P, Bäckström S, Furnander Å, Hovelius K - Department of Transportation and Logistics Chalmers University of Thechnology.
Reviewer	
Applicability	The data is taken from experimental production, and can therefore not be used with success to evaluate the present situation. Testing plants that need not function economically is not to be equalled to commercially producing plants. Because the environmental load is not proportional to the production amount this data should not be used on plants with much greater or smaller production. The data conserning the energy forest (Willow) used in the production can be found in SPINE in the activity Production of energy forest.

SPINE LCI dataset: Production of methylene diphenyl diisocyanate, MDI (APME)

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Production of methylene diphenyl diisocyanate, MDI (APME)
Functional Unit	1 kg MDI - Methylene diphenyl diisocyanate
Functional Unit Explanation	MDI, methylene diphenyl diisocyanate, is one of the precursors used in the production of polyurethanes. There are five main areas of use for polyurethanes: the furniture and mattress sector, the automotive industry, the consumer sector, the building industry and the
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. All flows have been followed to the cradle. However, only the main production process is been described here. MDI, methylene diphenyl diisocyanate, is one of the precursors used in the production of polyurethanes. MAIN PROCESS: 1. Extraction of crude oil 2. Oil refining 3. Benzene production 4. Nitrobenzene production 5. Aniline production 6. MDA (methylene dianiline) production 7. MDI production SUB PROCESSES: a. Production of sulphur and sulphuric acid, to be used in the production of nitrobenzene b. Production of hydrogen for the aniline production. c. Production of methanolo from natural gas - production of formaldehyde from the methanol. The formaldehyde is used for the MDA production. d. Production of ammonia from natural gas. The ammonia is used fro the benzene production. The ammonia is also used to produce nitric acid, which is used in the production of nitrobenzene. e. Production of phosgene from carbon monoxide and chlorine. The carbon monoxide is produced from coke/natural gas. The chlorine is produced from sodium chloride. The

	phosgene is used from the MDI production step. The inputs to the process are crude oil, natural gas, sulphur, coke/naturalgas, sodium chloride and the by-product sulphur dioxide. For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the year 1995-1996. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Data were supplied from 5 producers in Belgium, Germany, Italy and the Netherlands. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Metholodogy report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Results are based on data supplied by 5 MDIproduction plants in 4 countries: Belgium, Italy, Germany and the Netherlands. Their total production was 557,000 tonnes.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid

	cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

Flow Data

General Activity QMetaData

Date Conceived	1995-1996
Data Type	Derived, mixed
Represents	Not relevant.
Method	European average data. Results are based on data supplied by 5 MDI production plants in 4 countries: Belgium, Italy, Germany and the Netherlands. Their total production was 557,000 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstram raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. Data from APMEs website www.lca.apme.org have been downloaded as exe-files. The files are opened and imported into Microsoft Excel. Further, the data from MS Excel is exported to a MS Access database.
Literature Reference	APME - Association of Plastics Manufacturers in Europe, website: http://lca.apme.org
Notes	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature used by CPM (CPM 2000:2). The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New names: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', report for MDI. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. -- Documented by Caroline Sjöberg and Sofia Haargaard, Volvo Technological Development Documentation reviewed by: Ann-Christin Pålsson, IMI, Chalmers University of Technology Published in SPINE@CPM: 3 April 2002 --
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses. 1. Provide APME member companies with information which will highlight potential areas for improving manufacturing processes 2. Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies - Internal company benchmarking - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.

Applicability	The data are applicable to both MDI monomer and polymer; differences between the two have been found to be insignificant. European average data. Results are based on data supplied by 5 MDI production plants in 4 countries: Belgium, Italy, Germany and the Netherlands. Their total production was 557,000 tonnes. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.

About Data	European average data for MDI production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data are probably fairly representative for production of MDI in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission = 3,67 x {mass fraction of carbon in fuel}/{calorific value in MJ/kg} (kg/MJ fuel).

SPINE LCI dataset: Production of mounting fluid

Administrative	
Finished	Y
Date Completed	2002-12-12
Copyright	
Availability	Public

Technical System	
Name	Production of mounting fluid
Functional Unit	1 kg mounting fluid
Functional Unit Explanation	The density of SKF LHMF 300 is 0.894 kg/l.
Process Type	Gate to gate
Site	Huizingen, Belgium
Sector	Materials and components
Owner	Huizingen, Belgium
Technical system description	A mounting fluid is used for facilitate the mounting or dismounting of a bearing. The mounting fluid SKF LHMF 300 is fabricated from paraffinic mineral oil, alkyl metacrylate, and the anti rust additive long chain alkylcarboxilic acid.

System Boundaries	
Nature Boundary	No emissions are included since ther amount are regarded very small.
Time Boundary	Data is collected autumn 2002. No changes in the procedure are planned for the nearest future.
Geographical Boundary	The fabrication takes place at Huizingen, Belgium.
Other Boundaries	Electricity consumption is excluded due to lack of data. Transports are not included either.
Allocations	Not applicable
Systems Expansions	Not applicable

Flow Data	
General Activity QMetaData	
Date Conceived	2002-09-01 - 2002-12-31
Data Type	Unspecified, expert outspoke
Represents	N/A
Method	Personal communication with Harry Warmer and Magnus Rydin, SKF Maintenance Products.
Literature Reference	N/A

Notes	The alkyl metacrylate has been estimated with polymethyl metacrylate since no other information could be achieved.

About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Thechnology, December 2002. -------------- Data documented by Sandra Häggström, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-03-21.
Intended User	Product developer at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The purpose for our study is to compare a coated roller bearing to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll using SKF LHMF 300 in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .

SPINE LCI dataset: Production of nitric acid

Administrative

Finished	Y
Date Completed	1999-01-25
Copyright	
Availability	Public (confidential energy flow data are not included)

Technical System

Name	Production of nitric acid
Functional Unit	1 kg of nitric acid (100 %)
Functional Unit Explanation	
Process Type	Gate to gate
Site	Hydro Agri AB Box 908 SE-731 29 Köping Sweden
Sector	Materials and components
Owner	Hydro Agri AB Box 908 SE-731 29 Köping Sweden

Technical system description	The nitric acid production step is one step in the line of production of NPK fertilisers at the site in Köping. The nitric acid is neutralised with ammonia to produce ammonum nitrate that in turn is mixed with other components forming NPK fertilisers. At Hydro Agri AB in Köping there are two nitric acid plants. The old plant, built in 1956, has higher emissions and produces less energy than the new plant built in 1982. The old plant is operated at atmospheric pressure and the new plant built is operated at intermediate pressure. The dataset represents an average of the two plants. References: Miljörapport Hydro Agri AB Köping (1998). Official environmental report. Hydro Agri AB, Box 908, 731 29 Köping. Personal communication: Karlsson L-H (1998). Hydro Agri AB, Köping. Tel. +46 (0)221 27800

System Boundaries

Nature Boundary	The system starts with input of ammonia and energy and ends with nitric acid leaving the factory gate, i.e production of ammonia and energy are not not included in this dataset.
Time Boundary	The data are taken from production in 1997.
Geographical Boundary	The nitric acid plants are situated in Köping, Sweden.
Other Boundaries	
Allocations	Emissions of nitrogen to water and consumption/production of energy due to the nitric acid production are included in the emissions and energy consumption/production related to the production of ammonium nitrate.
Systems Expansions	Not applicable.

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	N/A
Method	Amount of ammonia consumed in the production of nitric acid was calculated by using the molecular mass of nitric acid and ammonia respectively. Average values for emissions of nitric oxides from the two nitric acid plants at the site were given in kg/d and these values were therefor multiplied by 365, summarised and then divided by the total amount of nitric acid produced at the plants in 1997. The total amount of emissions nitrous oxides was divided by the total amount of nitric acid produced at the two plants in 1997. Emissions of nitrogen to water and consumption/production of energy due to the nitric acid production are included in the emissions and energy consumption/production related to the production of ammonium nitrate.

About Inventory

Publication	Davis J, Haglund C (1999). ''Life Cycle Inventory (LCI) of Fertiliser Production - Fertiliser Products Used in Sweden and Western Europe''. SIK report no. 654. The Swedish Institute for Food and Biotechnology (SIK). Gothenburg, Sweden. -- Data documented by: Jennifer Davis, SIK (The Swedish Institute for Food and Biotechnology). Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The data are intended to be us
General Purpose	To generate an inventory of emissions and use of resources for the production of fertilisers used in Sweden.
Detailed Purpose	The purpose was not to compare the production of different fertilisers with each other, but to generate a thorough inventory of emissions and use of resources due to the production of different mineral fertilisers. Production of nitric acid is one process step in the production of fertilisers containing nitrogen. The data are intended to constitute a useful basis of input information in life cycle assessments of food production systems.
Commissioner	- SIK AB, The Swedish Institute for Food and Biotechnology Box 5401 SE-402 29 Gothenburg Sweden .
Practitioner	Davis, Jennifer and Caroline Haglund - SIK AB Box 5401 402 29 Gothenburg Sweden.
Reviewer	-
Applicability	The dataset is applicable for production of nitric acid used in fertiliser production at Hydro Agri AB in Köping, Sweden. The dataset is included in aggregated datasets for fertiliser production at Hydro Agri AB in Köping (cradle to gate).
About Data	Data are collected from the official environmental report distributed by Hydro Agri AB in Köping and also by comminication with Lars-Håkan Karlsson and Bo Andersson, Hydro Agri AB in Köping.
Notes	Internal review of the report was performed by: Olle Ramnäs, CTH (Chalmers University of Technology), Berit Mattsson and Magnus Stadig, SIK (The Swedish Institute for Food and Biotechnology).

Technical System	
Name	Production of nitric acid (Landskrona)
Functional Unit	1 kg of nitric acid (100 %)
Functional Unit Explanation	
Process Type	Gate to gate
Site	Hydro Agri AB Box 516 SE-261 24 Landskrona Sweden
Sector	Materials and components
Owner	Hydro Agri AB Box 516 SE-261 24 Landskrona Sweden
Technical system description	Production of nitric acid: Gaseous ammonia is mixed with pressurised air and the blend is combusted on a net of platina catalyst forming nitrogen monoxide. The process is operated at intermediate pressure. This reaction yields heat which is used to produce steam which in turn is partly used for internal heating within the system and partly transported to a district-heating network. The nitric monoxide gas is cooled and air is added, oxidising the nitrogen monoxide into nitrogen dioxide. The nitric acid is then dissolved in water in two absorption towers under intermediate pressure, forming nitric acid as final product. The tailgas from the two absorption towers is heated to 230 °C with incoming process gas. After addition of ammonia the tailgas is led to a NOX reactor where 90 % of the nitric oxides reacts on a catalyst into water and nitrogen gas. The residual gas passes a turbine that compresses the incoming air and a feed water heater before leaving the plant from a stack, 40 m in height. System Boundaries	
Nature Boundary	The nature boundary is at the incoming and outgoing factory gate, i.e production of electricity, steam, district heat and supply materials are not included.
Time Boundary	The data are figures for production in 1997.
Geographical Boundary	Hydro Agri AB in Landskrona, Sweden.
Other Boundaries	Emissions from production of electricity and ''negative'' emissions from production of steam and district heating are not included in this dataset.
Allocations	Not applicable.
Systems Expansions	Not applicable.

Flow Data	
General Activity QMetaData	
Date Conceived	1997-01-01
Data Type	Derived, unspecified

Represents	N/A
Method	Amount of ammonia consumed in the production of nitric acid was calculated by using the molecular mass of nitric acid and ammonia respectively. Example: M(NH3): 17g/mole M(HNO3): 63 g/mole Þ (17 g/mole) / (63 g/mole) = 0.27 t NH3/t HNO3 Total amounts of emissions of nitric oxides (NOx), nitrous oxides (N2O) and nitrogen (NO-3-N, NH4+-N) to water from the nitric acid plant have been divided by total amounts nitric acid produced in 1997. Emissions of nitric oxides (NOx) have been calculated as nitrogen dioxide. Example: M(N): 14 g/mole M(NO2): 46 g/mole Þ (35 t NOx-N/yr) / (94 000 t HNO3/yr) * (46 g/mole) / (14 g/mole) = 1.22 kg NOx/t HNO3 Total amounts of district heat and steam produced at the nitric acid plant have been divided by total amounts of nitric acid produced during 1997. Example: (62 500 MWh steam/yr) / (94 000 t HNO3/yr) * (3.6 GJ/MWh) = 2.39 GJ/t HNO3 The total net consumption of electricity (electricity is also produced at the plant) was divided by total amount of nitric acid produced in 1997. See also ''Specific QMetaData''.
Literature Reference	Miljörapport (official environmental report) 1997, Hydro Agri AB, Box 516, 261 24 Landskrona, Sweden. Personal communication: Göte Bertilsson (1998), Hydro Agri AB Landskrona, tel. +46 418 76100 Ronnie Persson (1998), Hydro Agri AB Landskrona, tel +46 418 76100
Notes	Emissions of nitrogen to water and consumption/production of energy due to the nitric acid production are included in the emissions and energy consumption/production related to the production of ammonium nitrate. The energy consumption/production is confidential.

About Inventory

Publication	Davis J, Haglund C (1999). ''Life Cycle Inventory (LCI) of Fertiliser Production - Fertiliser Products Used in Sweden and Western Europe''. SIK report no. 654. The Swedish Institute for Food and Biotechnology (SIK). Gothenburg, Sweden. --- Data documented by: Jennifer Davis, SIK (The Swedish Institute for Food and Biotechnology). Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology ---
Intended User	The data are intended to be us
General Purpose	To generate an inventory over emissions and use of resources due to the production of fertilisers used in Sweden.
Detailed Purpose	The purpose was not to compare the production of different fertilisers with each other but to generate a thorough inventory of emissions and use of resources due to the production of different mineral fertilisers. Production of nitric acid is one process step in the production of

	fertilisers containing nitrogen. The data are intended to constitute a useful basis of input information in life cycle assessments of food production systems.
Commissioner	- SIK AB, The Swedish Institute for Food and Biotechnology Box 5401 SE-402 29 Gothenburg Sweden .
Practitioner	Davis, Jennifer and Caroline Haglund - SIK AB Box 5401 402 29 Gothenburg Sweden.
Reviewer	-
Applicability	The dataset is applicable for production of nitric acid at Hydro Agri AB in Landskrona. The nitric acid production step is one step in the line of production of calcium ammonium nitrate (CAN) at the site in Landskrona. Nitric acid is neutralised with ammonia and mixed with dolomite to produce CAN. The dataset is included in the aggregated dataset for production of CAN fertiliser at Hydro Agri AB in Landskrona (cradle to gate).
About Data	Data are collected from the official environmental report distributed by Hydro Agri AB in Landskrona and also by contact with Ronnie Persson, Göte Bertilsson and Mats Karlsson, Hydro Agri AB in Landskrona.
Notes	Internal review of the report was performed by: Olle Ramnäs, CTH (Chalmers University of Technology), Berit Mattsson and Magnus Stadig, SIK (The Swedish Institute for Food and Biotechnology).

SPINE LCI dataset: Production of nonylphenol and dinonylphenol

Administrative	
Finished	Y
Date Completed	1997-03-01
Copyright	
Availability	Public

Technical System	
Name	Production of nonylphenol and dinonylphenol
Functional Unit	ton
Functional Unit Explanation	1 ton maufactured nonylphenol and dinonylphenol. The annual production of 1996 was 8128 ton nonylphenole and dinonylphenole. The amount of the sepatate substances are not stated. The two substances is produced in the same process.
Process Type	Gate to gate
Site	Akzo Nobel, Surface Chemistry AB Ågatan 44 431 37 Möndal Sweden
Sector	Materials and components
Owner	Akzo Nobel, Surface Chemistry AB Ågatan 44 431 37 Möndal Sweden
Technical system description	Production of nonyl phenol and dinonyl phenol. Alkylphenols are produced with a chemical reaction between the substances nonen and phenol. The reaction is accelerated by the catalyst borontrifluoride. The production is done batch by batch in a reactor, in which the slightly exothermal reaction leaves the substances mono- and dinonylphenol together with the non reacted phenole and nonen. The phenole and nonen is then cupeled to be recycledin a oil heated boiler. The gases contain small amounts of different kinds of carbon hydrigenes, which are taken up by the pack watera of the vacuum pump or is cupeled to be destroyed in a conbustion heat exchanger. Dissolved phenol in the pack water is separated and neutralized with potassium lye.Water containing potassium phenolate and nonreacted is treated (destroyed) in Stenungsund eller by SAKAB. Through distillation nonyl phenol and dinonyl phenol is produced. The higher alkylphenols

	that are restpruducts from the distillation are mixed with the fuel oil to be conbusted in a steem-boiler or a oil heated boiler. The nonyl phenol and the dinonyl phenol are stored to be put on barrel or to be delivered by tank lorry. Emission to the air is caused by the energy production in the process of making nonylphenol. Diffuse emissions are also made from the stock of tanks. Carbon hydrogenes, from the cupel column and the distillation columns of the process, that are not condensed are led to a combustion exchanger. The exchanger consist of a bedding of gravel in a segregated holder. Electrical heating spirals are situated in the center, and they keep the contaminations burning. The air is cleansed to at least 90%. The gas is cupeled to the atmosphere by a smoke-stack. Substances are not normally emitted to water.

System Boundaries

Nature Boundary	The company is not obligated to state other emission- or waste substances than the Swedish Environmental Protection law requires.
Time Boundary	The company is obligated to write an Environmental report once every year. Though the legislated limits can be changed only if the activity is changed.
Geographical Boundary	Sweden
Other Boundaries	
Allocations

About Inventory	
Publication	The environmental report from Akzo Nobel Surface Chemistry AB for 1996. The Environmental Administration in the municipality of Göteborg, Sweden -- Data documented by: Maria Erixson and Sara Ågren, project employed for the database projet at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	To show the environmental load
General Purpose	The purpose of the Environmental report is to be the base for permission trial of activities that is harmful to the environment and further to make shore that the company comply with the decision.
Detailed Purpose	To control that the legislated limits are not exceeded.
Commissioner	- Swedish government via The Board of County in Göteborg and Bohus or The Environmental Administration in the municipality of Göteborg. .
Practitioner	- Akzo Nobel, Surface Chemistry AB Ågatan 44 431 37 Möndal Sweden .
Reviewer	Billstedt L, Bording H - Akzo Nobel, Surface Chemistry AB Ågatan 44 431 37 Möndal Sweden
Applicability	
About Data	No margin of error is found in the report, and one can assume that a lot of values have been rounded. The plant has during 1996 been in operation 8100 h.
Notes	

SPINE LCI dataset: Production of NP 27-5 fertiliser

Administrative	
Finished	Y
Date Completed	1999-01-25
Copyright	

Availability	Public (confidential energy flow data are not included).

Technical System

Name	Production of NP 27-5 fertiliser
Functional Unit	1 kg of NP 27-5 fertiliser
Functional Unit Explanation	1 kg of Hydro NP Svavel 27-5, uncoated and unpacked. 27 % N and 5 % P.
Process Type	Gate to gate
Site	Hydro Agri AB Box 908 SE-731 29 Köping Sweden
Sector	Materials and components
Owner	Hydro Agri AB Box 908 SE-731 29 Köping Sweden
Technical system description	At the plant operated by Hydro Agri AB in Köping, NP 27-5 fertiliser is produced by the mixed acid route as follows: Ammonium nitrate is mixed with dolomite, phosphoric acid, ammonia and ammonium sulphate. The neutralisation with ammonia yields heat. The slurry is granulated, dried in a rotary drier, sifted, cooled and sifted again before final coating and storing.

System Boundaries

Nature Boundary	The system is a gate to gate system, it starts at the incoming factory gate and ends at the outgoing factory gate. Production of steam, electricity and input materials are outside the system boundary.
Time Boundary	The data are figures for production in 1997.
Geographical Boundary	Hydro Agri AB in Köping, Sweden.
Other Boundaries	Coatings, micronutrient and small additives have not been taken into account. Packaging of fertiliser has also been left outside the system boundary. Production and waste treatment of catalysts and production of capital goods are not included.
Allocations	Several different fertiliser products are produced at the Hydro Agri plant in Köping. Concerning consumption of energy and emissions of particulates to air, these have been allocated to the different products by mass of the products. Emissions of nitrogen to water and ammonia to air have been allocated to the different products by their mass content of nitrogen. Emissions of phosphorus to water heve been allocated according to mass content of phosphorus in the products.
Systems Expansions	Not applicable.

About Inventory

Publication	Davis J, Haglund C (1999). ''Life Cycle Inventory (LCI) of Fertiliser Production - Fertiliser Products Used in Sweden and Western Europe''. SIK report no. 654. The Swedish Institute for Food and Biotechnology (SIK). Gothenburg, Sweden. -- Data documented by: Jennifer Davis, SIK (The Swedish Institute for Food and Biotechnology). Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The data are intended to be us
General Purpose	To generate an inventory of emissions and use of resources due to the production of fertilisers used in Sweden and Western Europe.
Detailed Purpose	The purpose was not to compare production of different fertilisers with each other, but to generate a thorough inventory of emissions and use of resources due to this production. The data are intended to constitute a useful basis of input information in life cycle assessments of food production systems.
Commissioner	- SIK AB, The Swedish Institute for Food and Biotechnology Box 5401 SE-402 29 Gothenburg Sweden .
Practitioner	Davis, Jennifer and Caroline Haglund - SIK AB Box 5401 402 29 Gothenburg Sweden.
Reviewer	-
Applicability	The data are applicable for production of NP 27-5 fertiliser that is produced and used in Sweden. It can be assumed that the data are representative for all the NP 27-5 used in Sweden, but it is important to be aware of the fact that there may exist imports of NPK 27-5 into Sweden. However, it is likely that the NP 27-5 used in Sweden originates from Swedish production. The dataset is included in the aggregated dataset for production of NP 27-5 at Hydro Agri AB in Köping (cradle to gate).
About Data	The data are taken from a specific site in Sweden and are therefore reliable. The data are gathered from the official environmental report distributed by Hydro Agri AB in Köping and also from personal communication with people working there. There is only one plant in Sweden that produces NPK fertilisers and the data are therefore representative for Swedish production of NP 27-5.
Notes	Internal review of the report was performed by: Olle Ramnäs, CTH (Chalmers University of Technology), Berit Mattsson and Magnus Stadig, SIK (The Swedish Institute for Food and Biotechnology).

Technical System	
Name	Production of NP 27-5 fertiliser AGGR
Functional Unit	1 kg NPK fertiliser
Functional Unit Explanation	
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The production route of NP 27-5 fertiliser produced at Hydro Agri AB in Köping can be seen in the aggregated activity window. For information about each separate production step, please see each included dataset. Emissions from transports, energy consumption and production of steam, district heat and electricity have been included in the system by using information and emission factors from the database in LCAiT 3.0. LCAiT 3.0 is a computer programme created by CIT Ekologik in Gothenburg for practitioners of life cycle assessments. Production/consumption of steam is assumed to replace/be produced by combustion of oil (efficiency of 0.90). Oil has been chosen as fuel source, as it in terms of emissions lies between coal and natural gas. Included transports and assumptions made regarding transports are described below (transports cannot be seen in the aggregated activity window). Ammonia: The ammonia used in production of fertilisers in Sweden is purchased at the spot market in the Baltic Sea. This ammonia mostly originates from Russia and Poland. The ammonia has been assumed to origin from the area around Moscow. It has been assumed that the ammonia is transported by train from Moscow to the harbour in Ventspils in Latvia (1000 km, train, diesel) and then transported by boat to Köping (700 km, ship, bulk carrier). Pyrite: The pyrite used for production of phosphoric acid in Siilinjärvi, Finland, is mined in Outokumpu, Finland, and transported by truck (90 km, medium truck, rural, full) to Siilinjärvi. Rock phosphate: The rock phosphate is mined nearby Siilinjärvi and no transportation has therefore been included for this material. Phosphoric acid: The phosphoric acid used at Hydro Agri AB in Köping is then transported from Siilinjärvi to Köping by two different routes. Phosphoric acid with a concentration of 58 % P2O5 is transported from Siilinjärvi by train (300 km, train, diesel) to Kokkola and then by boat (400 km, ship, bulk carrier) via Uusikapuuki to Köping. Phosphoric acid with a concentration of 52 % P2O5 is transported from Siilinjärvi by train (540 km, train, diesel) to Uuskapuuki and then by boat (300 km, ship, bulk carrier) on to Köping. The concentration of phosphoric acid used in Köping is 55-56 % P2O5 and a concentration of 55.5 % has been assumed. This acid is a blend of the two acids, and consequently, 58 % are taken by train and boat to Uuskikapuuki and 42 % are taken by train to Uuskikapuuki. Dolomite: The dolomite used at Hydro Agri AB in Köping is transported by truck (55 km, medium truck, rural, full) to Köping. Ammonium sulphate (by-product from production of caprolactam and has therefore only been charged with transport): The ammonium sulphate is taken from the Czech Republic. During two thirds of the year it is transported via Lübeck and during one third via Gdansk in Poland. By the first route it is transported from north of Prague to Lübeck by barge (520 km, ship, coaster) and then on

	to Köping by boat (1000 km, ship, bulk carrier). On the second route, the ammonium sulphate is transported by train (500 km, train, diesel) from north of Prague to Gdansk. From Gdansk it is transported by boat (750 km, ship, bulk carrier) to Köping.

SPINE LCI dataset: Production of NPK 20-3-5 fertiliser

Administrative	
Finished	Y
Date Completed	1999-01-25
Copyright	
Availability	Public (energy flow data are confidential and not included).

Technical System	
Name	Production of NPK 20-3-5 fertiliser
Functional Unit	1 kg of NPK 20-3-5 fertiliser
Functional Unit Explanation	1 kg of Hydro NPK Svavel Bor 20-3-5, unpacked and uncoated. 20 % N, 3 % P och 5 % K
Process Type	Gate to gate
Site	Hydro Agri AB Box 908 SE-731 29 Köping Sweden
Sector	Materials and components
Owner	Hydro Agri AB Box 908 SE-731 29 Köping Sweden
Technical system description	At the plant operated by Hydro Agri AB in Köping, NPK 20-3-5 fertiliser is produced by the mixed acid route as follows: Ammonium nitrate is mixed with dolomite, potassium chloride, phosphoric acid and ammonia and kieserite. The neutralisation with ammonia yields heat. The slurry is granulated, dried in a rotary drier, sifted, cooled and sifted again before final coating and storing.

System Boundaries	
Nature Boundary	The system is a gate to gate system, it starts at the incoming factory gate and ends at the outgoing factory gate. Production of steam, electricity and input materials are not included in the system boundary.
Time Boundary	The data are taken from production in 1997.
Geographical Boundary	Hydro Agri AB in Köping, Sweden.
Other Boundaries	Coatings, micronutrient and small additives are not included in the system. Packaging of fertiliser has also been left outside the system boundary. Production and waste treatment of catalysts and production of capital goods are not included.
Allocations	Several different fertiliser products are produced at the Hydro Agri plant in Köping. Concerning consumption of energy and emissions of particulates to air, these have been allocated to the different products by mass of the products. Emissions of nitrogen to water and ammonia to air have been allocated to the different products by their mass content of nitrogen. Emissions of phosphorus to water heve been allocated according to mass content of phosphorus in the products.
Systems Expansions	Not applicable.

About Inventory

Publication	Davis J, Haglund C (1999). ''Life Cycle Inventory (LCI) of Fertiliser Production - Fertiliser Products Used in Sweden and Western Europe''. SIK report no. 654. The Swedish Institute for Food and Biotechnology (SIK). Gothenburg, Sweden. -- Data documented by: Jennifer Davis, SIK (The Swedish Institute for Food and Biotechnology). Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The data are intended to be us
General Purpose	To generate an inventory of emissions and use of resources due to the production of fertilisers used in Sweden and Western Europe.
Detailed Purpose	The purpose was not to compare the production of different fertilisers with each other but to generate a thorough inventory of emissions and use of resources due to this production. The data are intended to constitute a useful basis of input information in life cycle assessments of food production systems.
Commissioner	- SIK AB, The Swedish Institute for Food and Biotechnology Box 5401 SE-402 29 Gothenburg Sweden .
Practitioner	Davis, Jennifer and Caroline Haglund - SIK AB Box 5401 402 29 Gothenburg Sweden.
Reviewer	-
Applicability	The data are applicable for production of NPK 20-3-5 fertiliser that is produced and used in Sweden. It can be assumed that the data are representative for all the NPK 20-3-5 used in Sweden, but it is important to be aware of the fact that there may exist imports of NPK 20-3-5 into Sweden. However, it is likely that the NPK 20-3-5 used in Sweden originates from Swedish production.

About Data	The data are taken from a specific site in Sweden and are therefore reliable. The data are gathered from the official environmental report distributed by Hydro Agri AB in Köping and also from personal communication with people working there. There is only one plant in Sweden that produces NPK fertilisers and the data are therefore representative for Swedish production of NPK 20-3-5.
Notes	Internal review of the report was performed by: Olle Ramnäs, CTH (Chalmers University of Technology), Berit Mattsson and Magnus Stadig, SIK (The Swedish Institute for Food and Biotechnology).

Technical System	
Name	Production of NPK 20-3-5 fertiliser AGGR
Functional Unit	1 kg NPK fertiliser
Functional Unit Explanation	
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The production route of NPK 20-3-5 fertiliser produced at Hydro Agri AB in Köping can be seen in the aggregated activity window. For information about each separate production step, please see each included dataset. Emissions from transports, energy consumption and production of steam, district heat and electricity have been included in the system by using information and emission factors from the database in LCAiT 3.0. LCAiT 3.0 is a computer programme created by CIT Ekologik in Gothenburg for practitioners of life cycle assessments. Production/consumption of steam is assumed to replace/be produced by combustion of oil (efficiency of 0.90). Oil has been chosen as fuel source, as it in terms of emissions lies between coal and natural gas. Included transports and assumptions made regarding transports are described below (transports cannot be seen in the aggregated activity window). Ammonia The ammonia used in production of fertilisers in Sweden is purchased at the spot market in the Baltic Sea. This ammonia mostly originates from Russia and Poland. The ammonia has been assumed to origin from the area around Moscow. It has been assumed that the ammonia is transported by train from Moscow to the harbour in Ventspils in Latvia (1000 km, train, diesel) and then transported by boat to Köping (700 km, ship, bulk carrier). Pyrite The pyrite used for production of phosphoric acid in Siilinjärvi, Finland, is mined in Outokumpu, Finland, and transported by truck (90 km, medium truck, rural, full) to Siilinjärvi. Rock phosphate The rock phosphate is taken nearby Siilinjärvi and no transportation has therefore been included for this material. Phosphoric acid The phosphoric acid used at Hydro Agri AB in Köping is then transported from Siilinjärvi to Köping by two different routes. Phosphoric acid with a concentration of 58 % P2O5 is

	transported from Siilinjärvi by train (300 km, train, diesel) to Kokkola and then by boat (400 km, ship, bulk carrier) via Uusikapuuki to Köping. Phosphoric acid with a concentration of 52 % P2O5 is transported from Siilinjärvi by train (540 km, train, diesel) to Uuskapuuki and then by boat (300 km, ship, bulk carrier) on to Köping. The concentration of phosphoric acid used in Köping is 55-56 % P2O5 and a concentration of 55.5 % has been assumed. This acid is a blend of the two acids, and consequently, 58 % are taken by train and boat to Uuskikapuuki and 42 % are taken by train to Uuskikapuuki. Potassium chloride and kieserite The potassium chloride and kieserite used for production of fertilisers at Hydro Agri AB in Köping is mostly taken from the Werra region in Germany. It has been assumed that all the potassium chloride and Kieserite is transported from this region by train (380 km, train, diesel) to Wismar (Germany). From Wismar the materials are transported by boat (980 km, ship, bulk carrier) to Köping. Dolomite The dolomite used at Hydro Agri AB in Köping is transported by truck (55 km, medium truck, rural, full) to Köping.

SPINE LCI dataset: Production of nylon 66 (APME)

Administrative

Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System

Name	Production of nylon 66 (APME)
Functional Unit	1 kg of nylon 66 (PA 66)
Functional Unit Explanation	The polyamids (PA´s) are a group of polymers characterised by a carbon chain with -CO-NH- groups interspersed at regular intervals along it. They are commonly referred to by the generic name nylon and may be produced by the direct polymerisation of amino-acids or by the reaction of a diamine with a dibasic acid. PA 66 stands for polyamid with two monomers, adipin acid with 6 carbon atoms, and hexamethylene diamine with 6 carbon atoms. Typical uses for polyamids are: cable ties, lighter bodies, radiator end tanks, air intake manifolds, covers of various types, wheel covers, throttle bodies, clips, fasteners, ski bindings, switchgear, circuit breakers and electrical/electronic components
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. Nylon may be produced by the direct polymerisation of amino-acids or by the reaction of a diamine with a dibasic acid. The essential precursors for nylon 66 are hexamethylene diamine, and adipic acid. When they are reacted they produce hexamethylene diammonium adipate, commonly referred to as nylon salt. For fibre applications, it is important to ensure that the precursors are reacted in equimolar proportions and that the product is highly purified. The formation, extraction and purification of the salt ensures that these conditions are met. Adipic acid is made by the oxidation of cyclohexane to a mixture of cyclohexanol and

	cyclohexanone (called KA oil). This mixture is further oxidised with nitric acid to adipic acid. Hexamethylene diamine is made by the reduction of adiponitrile, which is made either by the electronic coupling of acrylonitrile or by the hydrocyanation of butadiene. Adipic acid and hexamethylene diamine are combined in water to make a salt solution. This solution is then passed through a batch or continous reactor in which the water is removed at high temperature and the nylon polymerises. The polymer is expelled from the reactor and granulated. Higher molecular weights are compounding of the the nylon with the modifiers or reinforcements. In some cases, it is possible to compound directly at the reactor without granulating the nylon. The results here refer to nylon66 containing 30% glass fibre. Operating conditions: As the data are based on information from 14 plants in 6 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the year 1995. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Data were supplied from 3 Nylon 66 producers in Germany and France. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Metholodogy report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Results are based on data supplied by 3 Nylon 66 production plants in 2 countries: France and Germany. Their total production was 28 000 tonnes.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following general co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene,

	propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

Flow Data

General Activity QMetaData

Date Conceived	1995
Data Type	Derived, mixed
Represents	N/A
Method	European average data. Results are based on data supplied by 3 Nylon 66 production plants in 2 countries: France and Germany. Their total production was 28 000 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstram raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. Data from APMEs website www.lca.apme.org have been downloaded as exe-files. The files are opened and imported into Microsoft Excel. Further, the data from MS Excel is exported to a MS Access database.
Literature Reference	APME, Association of Plastics Manufacturers in Europe, website: http://lca.apme.org/reports/htm/alphabetical.htm
Notes	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature used by CPM (CPM 2000:2) The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New names: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', report for nylon 66. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME´s web site http://lca.apme.org. -- Data documented by Caroline Sjöberg and Sofia Haargaard, Volvo Technological Development. Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 27 November 2001 ---
Intended User	1. APME member companies 2. L

General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses. 1. Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2. Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies - Internal company benchmarking - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	APME - Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels Belgium.
Practitioner	Boustead, Ian - .
Reviewer	
Applicability	European average data. Results are based on data supplied by 3 production plants in 2 countries: France and Germany. Their total production was 28 000 tonnes. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for nylon 66 production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data are probably fairly representative for production of nylon 66 in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity.

	According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission = 3,67 x {mass fraction of carbon in fuel}/{calorific value in MJ/kg} (kg/MJ fuel).
Notes	The following substance names have been changed from the nomenclature used by APME to adapt to nomenclature according to CPM report 2000:2. SPINE LCI dataset: Production of orthoxylene. ESA-DBP

Administrative	
Finished	Y
Date Completed	1997
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Production of orthoxylene. ESA-DBP
Functional Unit	1 kg of orthoxylene

Functional Unit Explanation	Unknown
Process Type	Gate to gate
Site	Unknown
Sector	Chemicals and chemical products
Owner	Unknown
Technical system description	Excerpt from the report, see 'Publication': ''Orthoxylene is made from naphtha. (...) This activity is described as a two step process. The naphtha has been replaced with refinery products (...).'' This process is included in the system described in: Beckman T. (1997). Gutenberg versus IT. A Life Cycle Assessment of printed and CD-stored information. Technical Environmental Planning, Report 1997:3, Chalmers University of Technology. Gothenburg, Sweden. Other processes in the CPM Database also included in the above publication: - Manufacturing of CD-R (Compact Disc-Recordable). ESA-DBP - Manufacturing of CD-ROM (Compact Disc - Read Only Memory). ESA-DBP - Dioctyl phthalate (DOP) production. ESA-DBP - Cultivation and felling of trees for papermaking. ESA-DBP - Cardboard production (MDF based). ESA-DBP - Production of copypaper. ESA-DBP

About Inventory

Publication	Beckman T. (1997). Gutenberg versus IT. A Life Cycle Assessment of printed and CD-stored information. Technical Environmental Planning, Report 1997:3, Chalmers University of Technology. Gothenburg, Sweden.
Intended User	LCA practitioner

General Purpose	The study was done for the purpose of master thesis.
Detailed Purpose	Excerpt from the report: ''The goal of this study is to undertake an life cycle assessment (LCA) of different alternatives for Ericsson to provide their customers with reference libraries to the Ericsson Consolo MD110 telephone exchange system. The different documentation alternatives investigated in this study are: plastic ring binders, paperbacks, CD-R records and CD-ROM records.''
Commissioner	Ericsson, Stockholm, Sweden - .
Practitioner	Torsten Beckman - .
Reviewer	Henrikke Baumann, - Environmental Systems Analysis, Chalmers University of Technology
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	NB: The inventory results for the whole life cycle (from cradle to grave) of binders, paperbacks, CD-Rs and CD-ROMs can be found in the reference report.

SPINE LCI dataset: Production of paint and anti corrosion agents

Administrative

Finished	Y
Date Completed	1996-03-01
Copyright	
Availability	Public

Technical System

Name	Production of paint and anti corrosion agents
Functional Unit	m3
Functional Unit Explanation	1 m3 produced paint and anti corrosion agents The actual production consists of 45,2% Paint (1. class) 34,4% Oil (2. class) 19,3% Mass (3. class) 1,16% Other products
Process Type	Gate to gate
Site	Geveko Industri AB Box 13007 40251 Göteborg
Sector	Materials and components
Owner	Geveko Industri AB Box 13007 40251 Göteborg
Technical system description	The company produces paint and anti corrosion agents through mixing of solid and liquid raw materials in mixers, dissolvers and reactors. Allowed production 20 000 m3 paint and anti corrosion agents.

System Boundaries

Nature Boundary	The company is not obligated to state other emission- or waste substances than the Swedish Environmental Protection law requires.
Time Boundary	The company is obligated to write an Environmental report once every year. Though the legislated limits can be changed only if the activity is changed.
Geographical Boundary	Sweden

About Inventory

Publication	The environmental report from Geveko Industri AB for 1995, The Board of County in Göteborg and Bohus -- Data documented by: Maria Erixson and Sara Ågren, project employed for the database projet at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	To show the environmental load
General Purpose	The purpose of the Environmental report is to be the base for permission trial of activities that is harmful to the environment and further to make shore that the company comply with the decision.
Detailed Purpose	To control that the legislated limits are not exceeded.
Commissioner	- The Environmental Administration in the municipality of Göteborg Box 360 401 25 Göteborg Sweden.
Practitioner	Tranberg Ulf - Geveko Industri AB Box 13007 40251 Göteborg.
Reviewer	- The Environmental Administration in the municipality of Göteborg Box 360 401 25 Göteborg Sweden

Applicability	The function of the technical system is not sufficently described. Contact the company to get the necessary details. No margin of error is found in the report, and one can assume that a lot of values have been rounded. The values often end with zeroes and occasionally are indicated to be an approximation.

Technical System	
Name	Production of paint, thinner and enamel mainly for surface treatment of steel
Functional Unit	m3
Functional Unit Explanation	1 m3 produced paint, enamel and thinner. The percentage of the different products is unspecified.
Process Type	Gate to gate
Site	International Färg AB Box 44 424 22 Angered Sweden
Sector	Materials and components
Owner	International Färg AB Box 44 424 22 Angered Sweden
Technical system description	The main ingredients in the paint production are pigments, binders and solvents, which are put together through powerful stirring. In some cases further grinding is necessary. This is done in sand mills. After the preparation, adjustment and control the product is filtrated and pored in to the packing in question. The production is secluded.

System Boundaries	
Nature Boundary	The company is not obligated to state other emission- or waste substances than the Swedish Environmental Protection law requires.
Time Boundary	The company is obligated to write an Environmental report once every year. Though the legislated limits can be changed only if the activity is changed.

Date concieved: 1996 Data type: Random sample Method: The taking of specimens is done by ÅF-IPK AB. The instrument used is an IR-Instrument of type Binos. The range of measurement of the IR-instrument is for CO2 0-20%. The instrument is calibrated with a known sample, and the margin of error is 2%.	Output	Emission	CO2	0.0904841			kg	Air	
	Output	Emission	NOx	0.0961097			kg	Air	
	Output	Emission	SO2	0.0452421			kg	Air	
Date concieved: 1996 Data type: Modeled data Method: The taking and analysing of specimens are done by the company ÅF-IPK AB, Kvarnbergsgatan 2, Box 1551, 401 51 Göteborg, Sweden, Phone number +46 (0)31 7431000. The amount of total hydrocarbon is measured with a devise which detects flam ionization. The ionization causes a signal, in the detector. The signal is approximately proportiunal to the	Output	Emission	VOC	2.21852			kg	Air	

amount of carbon, which through conbustion becomes carbon dioxide. This method is commonly used, and found to be relyable. It is also one of the few that allows continuous determination of the variation of the carbon content. Different carbon combines give different signal levels, because of the carbon's bond. This gives an error to the result. The instrument gives readings in parts per million. To get the reading in mg/m3 one multiplies with the mole mass of the substance in question and devides with the number of carbon atoms in 1 m3 air. The instrument used is Bernard Atomic 3005, and it has been calibrated with a known sample. The taking of specimens were done during W23 and W50. The level of production were not the same on two occations. Also the flow of gas and its temperature were measured during these weeks, so that the concentration could be converted to an amount. The flow of gas is measured by a Pitot tube and a micromanometer. The temperature is measured by thermal converter. The results: W24 2,2 kg emitted VOC per year and per m3 produced paint, when the level of production was 14 500 m3/year. W50 1,5 kg emitted VOC per year and per m3 produced paint, when the level of production was 11 300m3/year. To get the final result of the emitted VOC per year the results from the takning of specimens have to be converted to the actuall year limit of production . This is done by a calculation, which assumes a proportional connection between the limit of production and the emission. The company, hired to do the taking and analysing of the specimens, uses the highest allowed limit (18 000 m3/year) and not the actuall limit of production (12 621 m3/year), which is lower. the result then is 2,6 kg. The result given from this calculations is said to have approximatly 30% margin of error. In the environmental report International Färg AB uses the figure you get, when assuming you have the same limit of production the whole year as it was during W24. The value for the emitted VOC for this week was considerably higher than during the second measuring period (W50) and also noticeably higher than the actual level of production. Literature: The Environmental report from Internationel AB from 1996, The Environmental Administration in the municipality of Göteborg.

About Inventory

Publication	Tillman, A-M., H Baumann, E. Eriksson, and T. Rydberg, ''Life Cycle Analysis of Selected Packing Materials. Quantification of Environmental Loadings'' Offprint from SOU 1991:77. Chalmers Industriteknik, Göteborg, Sweden 1992. -- Data documented by: Maria Erixon and Sara Ågren, project employed at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Henrikke Baumann and Anne-Marie Tillman (responsible for the course material) and Ann-Christin Pålsson (responisble for classification of the dataset), Technical Environmental Planning, Chalmers University of Technology --
Intended User	A Life Cycle Assessment practi
General Purpose	The data set is part of a study about packaging and the environment.
Detailed Purpose	Exercise material in LCA coarse given at Teknisk Miljöplanering at Chalmers University of Technology, Sweden.

Commissioner	
Practitioner	Tillman, Anne-Marie - Technical Environmental Planning Chalmers University of Technology 412 96 Göteborg Sweden.
Reviewer	
Applicability	The data are valid for Swedish conditions, but can be used as an approximation to other countries. One should though be aware of the fact that the situation in other countries may be very different and depending on this get one gets an unreliable result. The data are based on old sources and should therefore not be regarded as information describing the current situation. There is no raw material going in to the system, which most lightly is the case. The raw material is low-pressure polyethylene. The emissions caused by the production of the electricity used in the system are not accounted for.

SPINE LCI dataset: Production of pentane (APME)

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Production of pentane (APME)
Functional Unit	1 kg pentane
Functional Unit Explanation	Pentane has the chemical structure CH3-CH2-CH2-CH2-CH3. Pentane is used as blowing agent for foams.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. All flows have been followed to the cradle. However, only the main production process is been described here. Pentane occurs naturally as part of the light fraction of crude oil and to a lesser extent in natural gas. It is readily extracted and purified during refinery operations. Smaller quantities of pentane occur as by-products in petrochemical processing and where there are sufficient quantities it is extracted for sale. For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the year 1990-1996. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Data were supplied from 3 pentane producers in France, Netherlands and Germany. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Metholodogy report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Results are based on data supplied by 3 pentane production plants in 3 countries: France, Germany and Netherlands. Their total production is not known: data was supplied in normalised format.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

Flow Data

General Activity QMetaData

Date Conceived	1990-1996
Data Type	Derived, mixed
Represents	See 'Function'
Method	European average data. Results are based on data supplied by 3 pentane production plants in 3 countries: France, Germany and Netherlands. Their total production is not known: data was supplied in normalised format. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstram raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. Data from APMEs website www.lca.apme.org have been downloaded as exe-files. The files are opened and imported into Microsoft Excel. Further, the data from MS Excel is exported to a MS Access database.
Literature Reference	APME, Association of Plastics Manufacturers in Europe, website: http://lca.apme.org
Notes	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature used by CPM (CPM 2000:2). The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New names: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.

About Inventory

Publication

''Eco-profiles of the European plastics industry'', report for pentane.
''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999.
Reports are available at APME's web site http://lca.apme.org.

Documented by Caroline Sjöberg and Sofia Haargaard, Volvo Technological Development

Documentation reviewed by: Ann-Christin Pålsson, IMI, Chalmers University of Technology

Published in SPINE@CPM: 3 April 2002

Intended User

1. APME member companies
2. L

General Purpose

The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.

Detailed Purpose

Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses.

1. Provide APME member companies with information which will highlight potential areas for improving manufacturing processes

2. Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products.

Objectives and areas of application for the Eco-profiles:
- Plastics waste management studies
- Internal company benchmarking
- Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems.
- Ensuring that the data are neutral.

The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies

	has improved since then.

Applicability	European average data. Results are based on data supplied by 3 pentane production plants in 3 countries: France, Netherlands and Germany. Their total production is not known: data was supplied in normalised format. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for pentane production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data are probably fairly representative for production of pentane in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission = 3,67 x {mass fraction of carbon in fuel}/{calorific value in MJ/kg} (kg/MJ fuel).

SPINE LCI dataset: Production of petrochemical Alcohol Ethoxylates (AE) with 3 moles of ethylene oxide (EO)

Administrative	
Finished	Y
Date Completed	1995-01-01
Copyright	Carl Hanser Verlag
Availability	Public

Technical System	
Name	Production of petrochemical Alcohol Ethoxylates (AE) with 3 moles of ethylene oxide (EO)
Functional Unit	1000 kg
Functional Unit Explanation	All emissions, use of resources and energy consumption is based on 1000 kg of AE (3 EO).
Process Type	Cradle to gate
Site	Europe
Sector	
Owner	Europe
Technical system description	BRIEF DESCRIPTION: The following steps are included in the production of fatty alcohol ethoxylate with 3 EO: Crude oil production: The study includes drilling, pumping and separation of crude oilk from brine water and tank storage. Crude oil refining: The refining includes desalting, hydrotreating and distillation (fractionation/extraction of crude oil into paraffins, olefins, benzene and ethylene). Natural gas production: The study includes drilling, pumping and tank storage. Natural gas processing: No details were given. Ethylene production: Ethylene is produced from natural gas and oil. n-Paraffin production: n-paraffins are produced from oil. Olefins production: Olefins are produced from ethylene and n-paraffins. Alcohol production: The alcohols are produced from olefins and ethylene. The production includes the production of methyl esters requiring methanol made from natural gas. Oxygen production: Oxygen is used in the process of making ethylene oxide. No details were given on oxygen production. Ethylene oxide production: Ethylene oxide is derived from ethylene and oxygen through an exothermic process. Alcohol ethoxylation (with 3 moles of ethylene oxide): Alcohol ethoxylates are produced by the reaction of detergent range alcohols with ethylene oxide. The addition of EO to detergent range alcohols leads to a distribution of homologue polyethylene glycoether groups. Information concerning all the subsystems described above: Transports are included in the system. The fuels for the transports and the fuels for the processes are traced back to the extraction of petrochemical raw materials and/or extraction of bio fuels. The electricity data are based on the electricity profile for each country and the petrochemical and biomass raw materials for electricity production are traced back to the extraction process (same process as for fuel raw materials).

System Boundaries	
Nature Boundary	All emissions are considered equivalent, independent of where they take place (locally, regionally, globally; in densely populated areas or rural areas).
Time Boundary	The process data used in the study pertain mainly to 1992, being yearly averages where possible. It is recognised that operating processes and conditions are constantly evolving. Indeed, one purpose of the study is to facilitate and encourage the use of systems with improved environmental profiles. Because such changes will inevitably occur, the data obtained in this study provide a reference against which they can be measured.
Geographical Boundary	This study examined the surfactant production in Europe, notably manufacturing processes conducted in Belgium, France, Germany, Italy, the Netherlands, Spain and the United Kingdom.
Other Boundaries	The detergent formulation, use and final disposal of the surfactants were not covered. The environmental effects associated with the manufacture of capital equipment and with energy and fuel requirements for plant and building conditioning (heat, air etc.) were not included, neither were those associated with personnel requirements. For electricity based on nuclear power and wind power, no emissions and resource exploits have been accounted for.
Allocations	Raw materials, energy and environmental emissions are allocated among co-products on an output weight basis, i.e. on the basis of mass. Co-products in this LCI include those materials that are currently recycled, reused or marketed in some beneficial way.
Systems Expansions	N/A (unless aggregated system from special type of comparative LCI study)

About Inventory	
Publication	Tenside Surfactants Detergents; 32. Jahrgang 2/1995; Carl Hanser Verlag; Munchen -- Data documented by: Malin Ericson, Akzo Nobel Surface Chemistry Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	All manufacturers and users of
General Purpose	-To produce an authoritative and comprehensive Life Cycle Inventory for major surfactant production in Europe through a common approach in order to facilitate objectivity in surfactant assessments on environmental grounds. -To secure the best possible validation of data and broad acceptance of the methodology and conclusions by industry, regulatory authorities, and academia, through assessment of the study by an appropriate expert review panel.
Detailed Purpose	-To establish an industry-wide inventory of the energy, emissions and resource exploits associated with the production of major surfactants in Western Europe under the conditions prevailing in 1992. -To bring together environmental data on the use of the main raw material sources - crude oil, natural gas, mineral, oleochemical, agricultural feedstock - for the processing pathways to the derived major surfactants. -To provide benchmarks for the processing steps of surfactant production against which individual producers can assess their own processes and identify opportunities for improvement. -To publish the results of the study and its conclusions in the open literature for access and reference by interested bodies.
Commissioner	- European LCI Surfactant Study Group (CEFIC/ECOSOL).
Practitioner	- Franklin Associates, Ltd. 4121 W. 83rd St., Suite 108 Prairie Village, KS 66208, USA.
Reviewer	Klöppfer, Prof. Dr. W. - C.A.U. Consultants Frankfurt, Germany

Applicability	It is generally not possible to replace one surfactant type by another without changing other components of a preparation, or altering performance characteristics. Therefore, it is not in general meaningful to compare surfactants on a weight basis. Alcohols ethoxylates are the largest group of nonionic detergent range alcohols.The particular alcohol ethoxylate covered in this study is mainly used in detergents. Alcohol ethoxylates are less sensitive to water hardness compared to anionic surfactants.
About Data	13 industrial companies participated in the project, including major surfactant manufacturers, raw material and intermediate suppliers, as well as surfactant users in Europe, some of whom are both manufacturers and users. Participating companies are BASF, Colgate-Palmolive, Condea, Enichem Augusta, Henkel, Hoechst, Hüls, ICI, Petresa, Procter & Gamble, Shell, Unilever and Wibarco. Process data were obtained directly from each company performing the process. These data were often proprietary. Therefore, technical process data from private corporations were collected from a minimum of three producers for each intermediate and surfactant type. The information is presented in the form of industry averages in order to preserve confidentiality. Fuel-related data for European countries were based on various governmental statistics and industry contacts (aggregated and provided by Dr. I. Bousted, The Open University, UK).
Notes	Data for other surfactants such as Alcohol sulphates (AS), Alcohol ethoxy sulphates (AES), soap, Secondary alkane sulphonates (SAS), Linear alkylbenzene sulphonates (LAS) and Alkyl polyglucosides (APG) were given in the same study.

SPINE LCI dataset: Production of petrochemical Alcohol Ethoxylates (AE) with 7 moles of ethylene oxide (EO)

Administrative	
Finished	Y
Date Completed	1995-01-01
Copyright	Carl Hanser Verlag, Munchen
Availability	Public

Technical System	
Name	Production of petrochemical Alcohol Ethoxylates (AE) with 7 moles of ethylene oxide (EO)
Functional Unit	1000 kg
Functional Unit Explanation	All emissions, use of resources and energy consumption is based on 1000 kg of AE (7EO).
Process Type	Cradle to gate
Site	Europe
Sector	
Owner	Europe
Technical system description	BRIEF DESCRIPTION: The following steps are included in the production of fatty alcohol ethoxylate with 7 EO : Crude oil production: The study includes drilling, pumping and separation of crude oilk from brine water and tank storage. Crude oil refining: The refining includes desalting, hydrotreating and distillation (fractionation/extraction of crude oil into paraffins, olefins, benzene and ethylene). Natural gas production: The study includes drilling, pumping and tank storage. Natural gas processing: No details were given. Ethylene production: Ethylene is produced from oil and gas.

	n-Paraffin production: n-paraffin is produced from oil. Olefins production: Olefins are produced from ethylene and n-paraffins. Alcohol production: The alcohols are produced from olefins and ethylene. The production includes the production of methyl esters requiring methanol made from natural gas. Oxygen production: Oxygen is needed in the production of ethylene oxide. No details were given on oxygen production. Ethylene oxide production: Ethylene oxide is derived from ethylene and oxygen through an exothermic process. Alcohol ethoxylation (with 7 moles of ethylene oxide): Alcohol ethoxylates are produced by the reaction of detergent range alcohols with ethylene oxide. The addition of EO to detergent range alcohols leads to a distribution of homologue polyethylene glycoether groups. Information concerning all the subsystems described above: Transports are included in the system. The fuels for the transports and the fuels for the processes are traced back to the extraction of petrochemical raw materials and/or the extraction of bio fuels. The electricity data are based on the electricity profile for each country and the petrochemical and biomass raw materials for electricity production are traced back to the extraction process (same process as for fuel raw materials).

System Boundaries

Nature Boundary	All emissions are considered equivalent, independent of where they take place (locally, regionally, globally; in densely populated areas or rural areas).
Time Boundary	The process data used in the study pertain mainly to 1992, being yearly averages where possible. It is recognised that operating processes and conditions are constantly evolving. Indeed, one purpose of the study is to facilitate and encourage the use of systems with improved environmental profiles. Because such changes will inevitably occur, the data obtained in this study provide a reference against which they can be measured.
Geographical Boundary	This study examined the surfactant production in Europe, notably manufacturing processes conducted in Belgium, France, Germany, Italy, the Netherlands, Spain and the United Kingdom.
Other Boundaries	The detergent formulation, use and final disposal of the surfactants were not covered. The environmental effects associated with the manufacture of capital equipment and with energy and fuel requirements for plant and building conditioning (heat, air etc.) were not included, neither were those associated with personnel requirements. For electricity based on nuclear power and wind power, no emissions and resource exploits have been accounted for.
Allocations	Raw materials, energy and environmental emissions are allocated among co-products on an output weight basis, i.e. on the basis of mass. Co-products in this LCI include those materials that are currently recycled, reused or marketed in some beneficial way.
Systems Expansions	N/A (unless aggregated system from special type of comparative LCI study).

Applicability	It is generally not possible to replace one surfactant type by another without changing other components of a preparation, or altering performance characteristics. Therefore, it is not in general meaningful to compare surfactants on a weight basis. It is estimated that approximately 40% of all detergent alcohols are transformed into alcohol sulphates. AS are also used in toiletry and cosmetic formulations such as schampoos, toothpastes and cosmetic lotions. The properties of AS are primarily determined by the molecular structure and chain lenth of the alcohol and the type of cation.

Technical system description	This dataset is intended to represent production of phosphoric acid that is used in the production of fertilisers at Hydro Agri AB in Köping. The data originate from reports on fertiliser production and no specific site has not been studied. The text below only gives general information about production of phosphoric acid, the data in this dataset do not necessarily represent these techniques. Further information about interpretations of what the data represent is given in the flow data window. This activity is also a part of the aggregated activity Production of NP 27-5 fertiliser AGGR. Production of phosphoric acid: As most phosphate ores have to be concentrated before they can be sold on the phosphate market and because different techniques may be used for doing this, the finished ore concentrate varies a great deal. This means that phosphoric acid technology, having to rely on raw materials of great variety, has to readapt itself constantly (BAT N° 4, 1995). There are several different process routes to produce phosphoric acid. The dihydrate (DH) process is the most diffused process (BAT N° 4, 1995). A dihydrate process can be considered to be made up by the following sections; grinding (not necessary for some phosphate ore, e.g. Kola rock), phosphoric reaction where gypsum is formed and filtration, where the product is separated from the gypsum crystals. The grinding is generally performed by ball or rod mills that can operate with both dry and wet rock. Wet rock is used for mineral-integrated unit operations, where rock beneficiation is achieved by washing or flotation. By feeding wet rock into the system, drying energy can be saved. The reaction of phosphate rock and sulphuric acid forming phosphoric acid and calcium sulphate (dihydrate form) takes place in an agitated single- or multitank. Ca3(PO4)2 + 3 H2SO4 ® 2 H3PO4 + 3 CaSO4 (s) The rock is initially kept in contact with recycled phosphoric acid to prevent an insoluble layer of calcium sulphate forming on the surface of the rock. a) Ca3(PO4)2 + 4 H3PO4 ® 3 Ca(H2PO4)2 b) 3 Ca(H2PO4)2+ 3 H2SO4 ® 3 CaSO4 (s) + 6 H3PO4 Calcium sulphate exists in a number of different crystal forms depending on temperature, P2O5 concentration and free sulphate content. In the production of phosphoric acid the operating conditions are generally selected so that the calcium sulphate is precipitated in either the dihydrate (CaSO4 . 2 H2O) or the hemihydrate (CaSO4 . 1/2 H2O) form (BAT N° 4, 1995). If operating conditions are selected so that the hemihydrate form is precipitated the phosphoric acid product will have a higher concentration of phosphorus than in the case

	of precipiting the dihydrate form. In the next stage phosphoric acid is separated from the calcium sulphate (gypsum) by filtration. Five tonnes of gypsum are generated for every tonne P2O5 of product acid produced. The phosphoric acid resulting from dihydrate operations yields 27-30 % P2O5 (Becker, 1989). Hemihydrate (HH) is also called the nonhydrate process and the main difference from the dihydrate process is that the calcium sulphate is participated in the hemihydrate form instead of the dihydrate form. The main advantage of this process is that evaporation heat requirements are reduced or eliminated due to the fact that an acid high in concentration is produced directly. Also, rock grinding requirements are lower because a satisfactory rate of reaction can be achieved from much coarser rock in the hemihydrate process. Disadvantages are e.g.; risk of slower filtration, phosphate losses and risk of corrosion due to a higher temperature and higher acid concentration than in the other processes (BAT N° 4, 1995). The weight of the produced gypsum is less than in the dihydrate process due to less water bound to each calcium sulphate molecule. Another method to obtain an acid high in concentration (40-52 % P2O5) directly, is by acidulating under hemihydrate conditions and separating the hemihydrate before recrystalling hemihydrate to dihydrate (HDH Process). The advantages of this method are energy savings due to the reduction or elimination of evaporation heat requirements, lower sulpuric acid consumption and that coarser rock can be used. It also produces a purer gypsum but the capital costs are high (BAT N° 4, 1995). The hemihydrate recrystalisation (HRC) process means acidulation under hemihydrate conditions and recrystallising to dihydrate without intermediate hemihydrate separation. This produces an acid of the same concentration as in the dihydrate process but the gypsum is much purer. This process consumes a lower quantity of sulphuric acid and a lower filter area but requires a fine rock grind and consumes evaporation heat (BAT N° 4, 1995). The dihemihydrate (DH/HH) process is another process. The method normally requires rock grinding and final rehydration of hemihydrate to dihydrate. The process produces a pure gypsum and consums a lower quantity of sulphuric acid (BAT N° 4, 1995). References: BAT N° 4 (1995). Notes	No data from a specific site have been obtained. Therefore, data for energy consumption has been equalled to average data for production in Western Europe stated by Kongshaug (1998).

Flow Table and Specific Meta Data

QMetaData	Direction	FlowType	Substance	Quantity	Min	Max	Unit	Environment	Geography
Notes: 100 % H2SO4.	Input	Natural resource	H2SO4	1.53			kg	Ground	Europe
Notes: 32 % P2O5. The rock phosphate used for production of the phosphoric acid that is used in Swedish fertiliser production originates from Finland and the source is igneous.	Input	Natural resource	Rock phosphate	1.73			kg	Ground	Europe
Method: According to Kongshaug (1998) the hemihydrate process is by far the most energy efficient process as the filter acid can be as high as 48-50 % P2O5. The dihydrate process produces a much weaker acid, resulting in a higher energy demand for evaporation. In Kongshaug (1998), a weighted value between the two levels of energy consumption has been calculated to produce an estimate of average energy consumption for production of phosphoric acid (54 % P2O5) in Western Europe today (Kongshaug, 1998). The figure given for an acid concentration of 54 % P2O5 has been chosen as representative for the concentration of 55.5 % as well, since the difference in energy consumption has been assumed to be of minor importance. The energy consumption given in Kongshaug (1998) corresponds well with figures given by Patyk (1996). A partition between the different energy sources steam and electricity for production of phosphoric acid used in Germany is given by Patyk (1996) and this partition has been assessed to be representative for the rest of Western Europe as well.	Input	Refined resource	Electricity	0.288			MJ	Technosphere	Europe

About Inventory

Publication	Davis J, Haglund C (1999). ''Life Cycle Inventory (LCI) of Fertiliser Production - Fertiliser Products Used in Sweden and Western Europe''. SIK report no. 654. The Swedish Institute for Food and Biotechnology (SIK). Gothenburg, Sweden. -- Data documented by: Jennifer Davis, SIK (The Swedish Institute for Food and

	Biotechnology). Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The data are intended to be us
General Purpose	To generate an inventory of emissions and use of resources due to the production of fertilisers used in Sweden.
Detailed Purpose	The purpose was not to compare the production of different fertilisers with each other, but to generate a thorough inventory of emissions and use of resources due to this production. Production of phosphoric acid is one step in the line of production of fertilisers containing phosphorus produced at Hydro Agri AB in Köping. The data are intended to constitute a useful basis of input information in life cycle assessments of food production systems.
Commissioner	- SIK AB, The Swedish Institute for Food and Biotechnology Box 5401 SE-402 29 Gothenburg Sweden .
Practitioner	Davis, Jennifer and Caroline Haglund - SIK AB Box 5401 402 29 Gothenburg Sweden.
Reviewer	-
Applicability	The dataset is applicable for production of phosphoric acid used in fertiliser production at Hydro Agri AB in Köping, Sweden. The phosphoric acid that is used in this production is imported from Kemira Chemicals OY in Siilinjärvi, Finland. The concentration of the acid delivered to Hydro Agri AB, Köping, is 55-56 % P2O5 and a concentration of 55.5 % has therefore been assumed. No was obtained for this specific production site, data have therefore been taken from literature. The dataset is included in aggregated datasets for fertiliser production at Hydro Agri AB in Köping (cradle to gate).
About Data	Data are gathered from literature, i.e. no specific site has been studied.
Notes	Internal review of the report was performed by: Olle Ramnäs, CTH (Chalmers University of Technology), Berit Mattsson and Magnus Stadig, SIK (The Swedish Institute for Food and Biotechnology).

Technical system description	This dataset is intended to represent production of phosphoric acid that is used in the production of fertilisers used in Western Europe. The data originate from reports on fertiliser production and no specific site has not been studied. The text below only gives general information about production of phosphoric acid, the data in this dataset do not necessarily represent these techniques. Further information about interpretations of what the data represent is given in the flow data window.

As most phosphate ores have to be concentrated before they can be sold on the phosphate market and because different techniques may be used for doing this, the finished ore concentrate varies a great deal. This means that phosphoric acid technology, having to rely on raw materials of great variety, has to readapt itself constantly (BAT N° 4, 1995).

There are several different process routes to produce phosphoric acid. The dihydrate (DH) process is the most diffused process (BAT N° 4, 1995). A dihydrate process can be considered to be made up by the following sections; grinding (not necessary for some phosphate ore, e.g. Kola rock), phosphoric reaction where gypsum is formed and filtration, where the product is separated from the gypsum crystals. The grinding is generally performed by ball or rod mills that can operate with both dry and wet rock. Wet rock is used for mineral-integrated unit operations, where rock beneficiation is achieved by washing or flotation. By feeding wet rock into the system, drying energy can be saved. The reaction of phosphate rock and sulphuric acid forming phosphoric acid and calcium sulphate (dihydrate form) takes place in an agitated single- or multitank.

$Ca_3(PO_4)_2 + 3 H_2SO_4$ ® $2 H_3PO_4 + 3 CaSO_4$ (s)

The rock is initially kept in contact with recycled phosphoric acid to prevent an insoluble layer of calcium sulphate forming on the surface of the rock.

a) $Ca_3(PO_4)_2 + 4 H_3PO_4$ ® $3 Ca(H_2PO_4)_2$

b) $3 Ca(H_2PO_4)_2 + 3 H_2SO_4$ ® $3 CaSO_4$ (s) $+ 6 H_3PO_4$

Calcium sulphate exists in a number of different crystal forms depending on temperature, P_2O_5 concentration and free sulphate content. In the production of phosphoric acid the operating conditions are generally selected so that the calcium sulphate is precipitated in either the dihydrate ($CaSO_4 . 2 H_2O$) or the hemihydrate ($CaSO_4 . 1/2 H_2O$) form (BAT N° 4, 1995). If operating conditions are selected so that the hemihydrate form is precipitated the phosphoric acid product will have a higher concentration of phosphorus than in the case of precipiting the dihydrate form.

In the next stage phosphoric acid is separated from the calcium sulphate (gypsum) by filtration. Five tonnes of gypsum are generated for every tonne P_2O_5 of product acid produced. The phosphoric acid resulting from dihydrate operations yields 27-30 % P_2O_5 (Becker, 1989).

Hemihydrate (HH) is also called the nonhydrate process and the main difference from the dihydrate process is that the calcium sulphate is participated in the hemihydrate form instead of the dihydrate form. The main advantage of this process is that evaporation heat requirements are reduced or eliminated due to the fact that an acid high in concentration is produced directly. Also, rock grinding requirements are lower because a satisfactory rate of reaction can be achieved from much coarser rock in the hemihydrate process. Disadvantages are e.g.; risk of slower filtration, phosphate losses and risk of corrosion due to a higher temperature and higher acid concentration than in the other processes (BAT N° 4, 1995). The weight of the produced gypsum is less than in the dihydrate process due to less water bound to each calcium sulphate molecule.

Another method to obtain an acid high in concentration (40-52 % P_2O_5) directly, is by acidulating under hemihydrate conditions and separating the hemihydrate before recrystalling hemihydrate to dihydrate (HDH Process). The advantages of this method are energy savings due to the reduction or elimination of evaporation heat requirements, lower sulpuric acid consumption and that coarser rock can be used. It also produces a purer gypsum but the capital costs are high (BAT N° 4, 1995).

The hemihydrate recrystalisation (HRC) process means acidulation under hemihydrate conditions and recrystallising to dihydrate without intermediate hemihydrate separation. This produces an acid of the same concentration as in the dihydrate process but the gypsum is much purer. This process consumes a lower quantity of sulphuric acid and a lower filter area but requires a fine rock grind and consumes evaporation heat (BAT N° 4, 1995).

The dihemihydrate (DH/HH) process is another process. The method normally requires rock grinding and final rehydration of hemihydrate to dihydrate. The process produces a pure gypsum and consums a lower quantity of sulphuric acid (BAT N° 4, 1995).

Flow Table and Specific Meta Data

QMetaData	***Direction***	***FlowType***	***Substance***	***Quantity***	***Min***	***Max***	***Unit***	***Environment***	***Geography***
Method: According to Kongshaug (1998) the hemihydrate process is by far the most energy efficient process as the filter acid can be as high as 48-50 % P2O5. The dihydrate process produces a much weaker acid, resulting in a higher energy demand for evaporation. In Kongshaug (1998), a weighted value between the two levels of energy consumption has been calculated to produce an estimate of average energy consumption for production of phosphoric acid (54 % P2O5) in Western Europe today (Kongshaug, 1998). A large part of the phosphoric acid consumed in Western Europe is imported from countries outside Western Europe, e.g. Morocco and it has been assumed that production techniques in these countries are comparable to production in Western Europe (Steen pers. comm., 1998). The energy consumption for production phosphoric acid is 3.8 GJ/t H3PO4 (54 % P2O5). The energy consumption for production of phosphoric acid (48 % P2O5) is 1 GJ/t P2O5 lower, as less energy for evaporation is needed, which results in 2.9 GJ/t H3PO4 (48 % P2O5) (Kongshaug, 1998). The energy consumption given in Kongshaug (1998) corresponds well with figures given by Patyk (1996). A partition between the different energy sources steam and electricity for production of phosphoric acid used in Germany is given by Patyk (1996)	Input	Refined resource	Electricity	0.213			MJ	Technosphere	Europe

and this partition has been assessed to be representative for the rest of Western Europe as well. With the energy consumption given by Kongshaug (1998) and the partition given by Patyk (1996), a resulting energy consumption of 2.7 GJ steam/t H3PO4 (48 % P2O5) and 0.2 GJ electricity/t H3PO4 (48 % P205) has been assumed to be representative for production of phosphoric acid used in Western Europe. The steam has been assumed to be produced by combustion of oil.									
Method: The consumption of sulphuric acid is assumed to be 1.49 t H2SO4 (100 %)/t phosphoric acid (54 % P2O5) as given in Kongshaug (1998). Notes: 100 % H2SO4.	Input	Refined resource	H2SO4	1.33			kg	Technosphere	Europe
Method: The amount of ore (32 % P2O5) that has to be dissolved to produce one tonne of phosphoric acid (48 % P2O5) is 1.5 t/t phosphoric acid. It has been assumed that no phosphorus is intergrown in the gypsum waste. In reality this is not true since 1.5-7 % of the phosphorus may end up in the gypsum depending on which process that has been used (Fertilizer Manual, 1998). Notes: Commercial rock phosphate; 32 % P2O5.	Input	Refined resource	Rock phosphate	1.5			kg	Technosphere	Europe
Method: According to Kongshaug (1998) the hemihydrate process is by far the most energy efficient process as the filter acid can be as high as 48-50 % P2O5. SPINE LCI dataset: Production of pig iron

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Production of pig iron
Functional Unit	0,2664 kg pig iron

Functional Unit Explanation	
Process Type	Gate to gate
Site	SSAB Luleå
Sector	Materials and components
Owner	SSAB Luleå
Technical system description	This activity describes a process step included in the system ''Production of guide rings used for spherical roller bearings'', also available in the SPINE@CPM database. The pig iron will be used as raw material for the production of guide rings at SKF Mekan AB in Katrineholm. The guide rings will later be mounted into the SKF Spherical Roller Bearing 232/530. The function is to assure that the rollers stay in the raceways of the bearing. Pig iron is produced in Russia and is transported with freighter and truck to SKF Mekan AB in Katrineholm. The raw material is iron ore which is smelted in a blast furnace and rolled into billets. Since no information was available from the Russian producer, this dataset refer to production of pig iron at SSAB in Luleå, Sweden. The data for the calculations is obtained from an earlier LCA study of the bearing housing SNL 511-609: Rasmus Beckman and Henrik Olsson; Vilken miljöpåverkan uppstår vid tillverkningen av ett lagerhus?; Master Thesis at Kalmars University; August 2002.

Technical System	
Name	Production of pig iron - blast furnace process. ESA-DBP
Functional Unit	1 kg of pig iron
Functional Unit Explanation	

Process Type	Gate to gate
Site	Unknown
Sector	Mining and quarrying
Owner	Unknown
Technical system description	Excerpt from the report, see 'Publication': ''The blast furnace is fed with ore, sinter, coke, lime and several minor inputs. The mass is heated and the ore is reduced by the carbon in the coke and by carbon monoxide produced by partial combustion of the coke. The pig iron is created at about 1700 'C. The sources of air pollution from the blast furnace are blast furnace gas, cast house emissions, slag handling and procesing. The rate of gas production is linked to smelting efficiency. The fume emissions from the cast house arises as a result from vaporisation of exposure to air and oxidation.'' This process is included in the system described in: Thuresson J. (1996). Life Cycle Assessment of Water Pumps. Technical Environmental Planning, Report 1996:11 ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Other processes in the CPM Database also included in the above publication: - Coal mining and cleaning. ESA-DBP - Cast iron production. ESA-DBP - Limestone quarrying. ESA-DBP - Sand extraction and processing. ESA-DBP - Sinter plant's process ESA-DBP - Uranium ore extraction and enrichment. ESA-DBP

About Inventory

Publication	Thuresson J. (1996). Life Cycle Assessment of Water Pumps. Technical Environmental Planning, Report 1996:11 ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden.
Intended User	LCA practitioner
General Purpose	Excerpt from the report, see 'Publication': ''The aim of the study is to undertake an LCA of typical water and sewage pumps. Those aspects which have a major contribution to the environmental impact in the life cycle of a pump will be identified.''
Detailed Purpose	Cast iron is a main material in a water pump (90%).

Sector	Materials and components
Owner	Järund Inventering AB Box 44 450 71 Fjällbacka Sweden

Technical system description	The company produces plastic strips and films. The products are manufactured in the following lines. Monoblister film Two production lines are in order to produce monoblister film. The main raw material used is LD-polyethylene. The plastic is treated in an extruder at 160-180 deg C, and is divided by a tool, from which the plastic is shaped into a blister. the blister is led up to the cealing where it is pulled off so that the film is cooled and flattened. The film is cut and rolled on to a roll. Coextruderad plane film The raw material, consisting of HD-polyethylene and LD-polyethylene, is worked together at a temperature of 200-220 deg C. The film is shaped and rolled on to a roll, where it is cut and wound. Extrution coating Thinn polyester film is treated and covered with primer. Primer, hardener and solvents are mixed and are pumped to the production line in a closed system. The primer is dryed in drying tunnel, and the solvent is combustioned catalyticly. The dry film is then covered with LD-polyethylene at a temperature of 280-320 deg C. Plastic smoke is made at the high temperature. The smoke is combusted in the compustion plant. Coextrusion blister film The raw material is worked at a temperature of 180-220 deg C in five different vessels. The materials are shaped and are brought together with a five layer tool. The film blister is lifted upp from a ring shaped mouthpiece and is cooled by large amounts of air, from a cooling ring around the tool. A rotating roll pulls off flattens the film at 17 meter above the ground. The film is then rolled upp again on rolls. Other Production Films are cut into plastic strips in approx. 30 cutting machines. Covers for thermometers are made of plastic film. Plastic film made of poly propylene is covered with a mixture of glue and chloric salt. UV-enamel is put on the product as protection. The use of fuel is limited by recycling of heat in the processes.

System Boundaries

Nature Boundary	The company is not obligated to state other emission- or waste substances than the Swedish Environmental Protection law requires.
Time Boundary	The company is obligated to write an Environmental report once every year. Though the legislated limits can be changed only if the activity is changed.
Geographical Boundary	Sweden
Other Boundaries	The waste paper consisting of pasteboard and cardboard is gathered for material recycling. The waste paper is transported by Tanums Lastbilscentral. the amount of waste paper is not stated in the environmental report.
Allocations	
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1995
Data Type	Unspecified
Represents	See 'Function'
Method	Study the Environmental report The data in the table has been converted into amounts per functional unit. The data from the environmental report has therefore been devided by the annual production for 1995, which was 4600 ton plastic strips and films.
Literature Reference	Thuresson J. (1996). Life Cycle Assessment of Water Pumps. Technical Environmental Planning, Report 1996:11 ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Data for particular process come from: Boustead I. and Hancock G.F. (1982), Energy and Recycling in Steel Production Systems, Resources and Conservation, 9, 209-218, Elsevier Scientific Publishing Company United Nations Environment Programme (UNEP) (1986), Environmental Aspects of Iron and Steel Production, A Technical Review, Industry & Environment Office
Notes	The data type unspecified implies that one does not know the origin of the data.

SPINE LCI dataset: Production of plywood boxes

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Production of plywood boxes
Functional Unit	One plywood box: 52,61 kg
Functional Unit Explanation	One Plywood box (Nefab ExPak type-S, 1160 x 1160 x H) weighs 52,61 kg. This box is used to transport the SKF spherical roller bearing 232/530 from SKFs site in Göteborg to customers around the world.
Process Type	Cradle to gate
Site	Nefab Emballage ABNordgrens väg 5 822 92 ALFTA SWEDEN
Sector	Materials and components

Owner	Nefab Emballage ABNordgrens väg 5 822 92 ALFTA SWEDEN
Technical system description	Plywood boxes are used to pack the coated and non-coated roller bearings from SKF, Göteborg, during the transportation to customers. The plywood boxes are manufactured by Nefab Emballage AB in Alfta, Sweden. This dataset includes the following process steps: (all eight are available in the SPINE@CPM database) 1. Plywood production 2. Virgin Steel Production 3. Hot rolling of steel sheet 4. Pickled hot rolled steel sheet 5. Cold reducing of steel sheets 6. Metal coating of cold reduced steel sheets 7. Production of wood 8. Manufacturing of plywood boxes at Nefab in Alfta The transports included in this dataset are: A. Transportation of rawmaterial for plywood production in Russia B. Transport by truck, train and freighter of plywood from Russia to Alfta in Sweden. C. Transport by truck of steel from Borlänge to Alfta. D. Transport by truck of wooden splits from local sawmill to Alfta. E. Transport by truck of steel nails from Uddevalla to Alfta. All production of electricity is included in the dataset. Also production of other energy carrier (Diesel, LPG, Heavy fuel oil) is included in the dataset and should not be taken into account. The plywood boxes consist of the following parts: Contents per box Weight (kg) % of total weight Plywood 33.9 64.44 Wooden splits 14.9 28.32 Steel strips 3.7 7.03 Steel nails 0.108 0.21 1. Production of plywood Plywood is built by wooden veneer sheets, which are crossed and put together through gluing. Characteristic of plywood is very high durability comparing to weight. Nefab Emballage AB uses plywood (birch wood) from different production plants in St Petersburg, Russia, but no LCI data was available from their Russian suppliers. Instead data for Swedish plywood (pine wood) is used. The used data refers to an EPD of wooden based board, 7 mm pinewood, produced by Edsbyn Träförädling AB [Environmental Product Declaration from Trätek, Sweden -9709077; 1997]. The inventory starts from extraction of resources and ends at the gate of the company. The raw material for the plywood production must be transported to the production plants in Russia. This has been included in the study and data is obtained from an LCA made at Nefab Emballage AB [Hillvall Maria; Transportförpackningars bidrag till reduktion av miljöbelastningen; Master Thesis at the Technical University of Luleå; 2000.]. Also the transport from Russia to Alfta in Sweden is considered and calculated from above mentioned study. The packaging material however is not included. 2. Virgin Steel Production Steel nails are used to attach the wooden splits to the plywood box. Steel strips are used to make the box more durable and lasting. Scanfast AB in Uddevalla, Sweden, supplies the steel nails and Tibnor AB in Borlänge, Sweden supplies the steel strips. All material from the suppliers to Nefab Emballage AB in Alfta is assumed to be transported by truck. For the steel production of all steel used in the plywood box, data from an earlier LCA study is used [Maria Sunér; Life Cycle Assessment of Aluminium, Copper and Steel; Technical Environmental Planning; Report 1996:6; Chalmers University of Technology; Gothenburg; Sweden] This dataset is obtained from the SPINE@CPM database. 3. Rolling of steel 4. Pickled hot rolled steel sheets 5. Cold reducing of steel sheets 6. Metal coating of cold reduced steel sheets When producing the steel strips, the steel from the steel mill is hot rolled, pickled, cold reduced and finally coated at SSAB Tunnplåt`s line in Borlänge. All data for these processes is obtained from an already made LCA at Nefab Emballage AB. The data refers mostly to existing EPDs from SSAB Tunnplåt AB. The steel nails are assumed not to be coated and thus the only process included after the production of steel is hot rolling of steel sheets. 7. Production of wooden splits Wooden splits are attached to the bottom of the box to enable forklift handling. Nefab Emballage AB buys the wooden splits from a local sawmill, Alfta Pall AB, in Alfta, Sweden. The database in LCAiT - production of 1 kg of wood for package use in Sweden - is used [Tillman et al., Chalmers Industriteknik, Gothenburg, Sweden, 1992. Packaging and the Environment, Tillman et al., Chalmers Industriteknik, Gothenburg, Sweden, 1992.]. The

	data includes transports and extraction of raw material. 8. Manufacturing of plywood boxes at Nefab in Alfta At Nefab Emballage AB in Alfta the plywood box is mounted, from its ingoing parts: Plywood, Steel strips, Wooden splits and steel nails. The used data refers to an EPD from Nefab Emballage AB for the product NEFAB Expak [Environmental Product Declaration from NEFAB Emballage AB; Doc.no.5-073-103.]. The environmental profile includes emissions from local energy use and internal transportation. The presumed product in the EPD contains plywood (87%) and steel strip (13%).

System Boundaries

Nature Boundary	Emissions to air and to water are included. The steel used for the steel strips and the nails are assumed to be virgin steel, and is followed from the cradle. See under each separate subactivity in Function for more detailed information.
Time Boundary	The data is gathered during the autumn 2002 and no changes in the procedure are planned for the nearest future. See under each separate subactivity in Function for more detailed information.
Geographical Boundary	The plywood production takes place at different suppliers in the area around St Petersburg, Russia. Production of steel and wood take place in Sweden. The final production of the plywood box takes place at Nefab Emballage AB in Alfta, Sweden.
Other Boundaries	All production of electricity is included in the dataset. Also production of other energy carrier (Diesel, LPG, Heavy fuel oil) is included in the dataset and should not be taken into account. This includes also the transports. The transports included in this dataset are: A. Transportation of rawmaterial for plywood production in Russia (plywood, 100 km by truck and 500 km by train), (glue, 300 km by train) B. Transport by truck, train and freighter of plywood from Russia to Alfta in Sweden. (truck 467 km, diesel train 77 km, electric train 283 km, freighter 224 km) C. Transport by truck of steel from Borlänge to Alfta. (114 km) D. Transport by truck of wooden splits from local sawmill to Alfta. (50 km) E. Transport by truck of steel nails from Uddevalla to Alfta. (570 km)
Allocations	Allocations have been made according to weight and composition from ingoing components (%).
Systems Expansions	Not Applicable

Flow Data

General Activity QMetaData

Date Conceived	02-08-01 - 02-12-31
Data Type	Derived, mixed
Represents	See 'Function'
Method	The data is gathered from interviews with Kjell-Arne Jonsson at Nefab Emballage AB in Alfta. Much of the data is taken from earlier LCA studies. See under the sub activities for more detailed information. Distances and type of transportations are taken from: * Hillvall Maria; Transportförpackningars bidrag till reduktion av miljöbelastningen; Master Thesis at the Technical University of Luleå; 2000. * Weström Pär, Packforsk Consulting AB; Simplified life cycle assessment for the comparison of two packaging alternatives for medium-sized roller bearings; Report no. C00 528; April 2001.
Literature Reference	* Hillvall Maria; Transportförpackningars bidrag till reduktion av miljöbelastningen; Master Thesis at the Technical University of Luleå; 2000. * Weström Pär, Packforsk Consulting AB; Simplified life cycle assessment for the comparison of two packaging alternatives for medium-sized roller bearings; Report no. C00 528; April 2001. * Environmental Product Declaration from NEFAB Emballage AB; Doc.no.5-073-103.
Notes	The data type unspecified implies that one does not know the origin of the data.

About Inventory

Publication	Master thesis: LCA based solution selection; Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. Both types of bearings are packed in a plywood box. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The dataset is applicable to plywood boxes of this dimension manufactured by Nefab Emballage AB in Alfta, Sweden. Care must be taken since transportation is included in the dataset. Raw material must thus come from the same suppliers or suppliers in the same area.
About Data	The data is gathered from interviews with Kjell-Arne Jonsson at Nefab Emballage AB in Alfta. Much of the data is taken from earlier LCA studies. See under the subactivities for more detailed information. Distances and type of transportations are taken from:

	* Hillvall Maria; Transportförpackningars bidrag till reduktion av miljöbelastningen; Master Thesis at the Technical University of Luleå; 2000. * Weström Pär, Packforsk Consulting AB; Simplified life cycle assessment for the comparison of two packaging alternatives for medium-sized roller bearings; Report no. C00 528; April 2001.

SPINE LCI dataset: Production of polyamid 66 containing 30% glass fibre (APME)

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Production of polyamid 66 containing 30% glass fibre (APME)
Functional Unit	1 kg of polyamid 66 containing 30% glass fibre.
Functional Unit Explanation	The polyamids (PA´s) are a group of polymers characterised by a carbon chain with -CO-NH- groups interspersed at regular intervals along it. They are commonly referred to by the generic name nylon and may be produced by the direct polymerisation of amino-acids or by the reaction of a diamine with a dibasic acid. Typical uses of polyamids: - radiator end tanks - air intake manifolds - covers of various types.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. Production of polyamid 66 include all major operations from extraction of crude oil and gas to catalytic reforming of naphtha, solvent extraction and fractional distillation. Nylon (PA66) may be produced by the direct polymerisation of amino-acids or by the reaction of a diamine with a dibasic acid. The essential precursors for nylon 66 are hexamethylene diamine, and adipic acid. When they are reacted they produce hexamethylene diammonium adipate, commonly referred to as nylon salt. For fibre applications, it is important to ensure that the precursors are reacted in equimolar proportions and that the product is highly purified. The formation, extraction and purification of the salt ensures that these conditions are met. Adipic acid is made by the oxidation of cyclohexane to a mixture of cyclohexanol and cyclohexanone (called KA oil). This mixture is further oxidised with nitric acid to adipic acid. Hexamethylene diamine is made by the reduction of adiponitrile, which is made either by the electronic coupling of acrylonitrile or by the hydrocyanation of butadiene. Adipic acid and hexamethylene diamine are combined in water to make a salt solution. This solution is then passed through a batch or continous reactor in which the water is removed at high temperature and the nylon polymerises. The polymer is expelled from the reactor and granulated. Higher molecular weights are compounding of the the nylon with the modifiers or reinforcements. In some cases, it is possible to compound directly at the reactor without granulating the nylon. The results here refer to nylon66 containing 30% glass fibre. Operating conditions: As the data are based on information from 3 plants in 2 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity

	production efficiency. For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries	
Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the year 1995. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Data were supplied from 3 polyamide producers in Germany and France. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Metholodogy report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Results are based on data supplied by 3 polyamid production plants in 2 countries: France and Germany. Their total production was 13 000 tonnes.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following general co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or

	chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

Flow Data

General Activity QMetaData

Date Conceived	1995
Data Type	Derived, mixed
Represents	
Method	European average data. Results are based on data supplied by 3 polyamid production plants in 2 countries: France and Germany. Their total production was 13 000 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstram raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. Data from APMEs website www.lca.apme.org have been downloaded as exe-files. The files are opened and imported into Microsoft Excel. Further, the data from MS Excel is exported to a MS Access database.
Literature Reference	APME, Association of Plastics Manufacturers in Europe, website: http://lca.apme.org/reports/htm/alphabetical.htm www.lca.apme.org
Notes	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature used by CPM (CPM 2000:2) The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New names: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', report for PA66+30%GF. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. --- Documented by Caroline Sjöberg and Sofia Haargaard, Volvo Technological Development Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 5 September 2001 ---
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses. 1. Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2. Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies - Internal company benchmarking - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	APME - Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels Belgium.
Practitioner	Boustead, Ian - .
Reviewer	-
Applicability	European average data. Results are based on data supplied by 3 polyamid production plants in 2 countries: France and Germany. Their total production was 13 000 tonnes. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful.

	It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for polyamid 66 with 30% glass fibre - production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data are probably fairly representative for production of PA66+30%GF in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Note that emissions <0,5 mg (0,25 mg in data table) may be far below 0,5 mg in some cases. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission = 3,67 x {mass fraction of carbon in fuel}/{calorific value in MJ/kg} (kg/MJ fuel).
Notes	The following substance names have been changed from the nomenclature used by APME to adapt to nomenclature according to CPM report 2000:2. SPINE LCI dataset: Production of polybutadiene (APME)

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Production of polybutadiene (APME)
Functional Unit	1 kg polybutadiene
Functional Unit Explanation	Typical uses for polybutadiene are production of ABS (Acrylonitrile-butadiene-styren copolymer) and synthetic rubbers.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. All flows have been followed to the cradle. However, only the main production process is been described here. Polybutadiene is produced by free radical polymerisation of butadiene; indeed one of the problems in storing butadiene is to prevent polymerisation. Polymerisation is usually carried out in suspension or emulsion. For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries	
Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names

	elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the years 1992-1995. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Data were supplied from 4 polybutadiene producers in Germany and Italy. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Metholodogy report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Results are based on data supplied by 4 polybutadiene production plants in 2 countries: Germany and Italy. Their total production was 88,000 tonnes.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

General Activity QMetaData

Date Conceived	1992-1995
Data Type	Derived, mixed
Represents	

Method	European average data. Results are based on data supplied by 4 polybutadiene production plants in 2 countries: Germany and Italy. Their total production was 88,000 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstram raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. Data from APMEs website www.lca.apme.org have been downloaded as exe-files. The files are opened and imported into Microsoft Excel. Further, the data from MS Excel is exported to a MS Access database.
Literature Reference	APME, Association of Plastics Manufacturers in Europe, website: http://lca.apme.org
Notes	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature used by CPM (CPM 2000:2). The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New names: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', report for polybutadiene. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. --

	Documented by Caroline Sjöberg and Sofia Haargaard, Volvo Technological Development Documentation reviewed by: Ann-Christin Pålsson, IMI, Chalmers University of Technology Published in SPINE@CPM: 3 April 2002 --
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses. 1. Provide APME member companies with information which will highlight potential areas for improving manufacturing processes 2. Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies - Internal company benchmarking - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.

Applicability	European average data. Results are based on data supplied by 4 polybutadiene production plants in 2 countries: Germany and Italy. Their total production was 88,000 tonnes. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for polybutadiene production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data are probably fairly representative for production of polybutadiene in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant).

	Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission = 3,67 x {mass fraction of carbon in fuel}/{calorific value in MJ/kg} (kg/MJ fuel).

SPINE LCI dataset: Production of polyethylene resin (HDPE), (APME)

Administrative	
Finished	Y
Date Completed	1999

Copyright	APME
Availability	Public

Technical System

Name	Production of polyethylene resin (HDPE), (APME)
Functional Unit	1 kg of high density polyethylene resin (HDPE)
Functional Unit Explanation	High density Polyethylene resin (HDPE) can be used to make various items. The structure of the molecule is the simplest of the polymers used in commercial production. Typical uses for high density polyethylene resin are: food containers, automobile fuel tanks, bottles, pipes and film.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. The polyolefins (polyethylene and polypropene) are chemically the simplest of the polymers in commercial production. They are usually polymerised by a free radical mechanism whereby an initiator opens the double bond of the alkene molecule and attaches itself leaving the other ''open'' bond, or radical free to attac a further alkene molecule. The process repeats itself until all of the monomer is used up or, more commonly, the reactive end is itself terminated by specifically added reactants. Depending on how the polymerisation reaction is carried out, the polymer chains may be highly linear or they may be side branched. The length and frequency of the side chains plays an important part in determining the ultimate properties of the polymer. Linear chains, chains with fex side branches and chains with very short side branches, allow the polymer to pack in a regular structure in the solid state, producing a high density, crystalline structure with superior mechanical properties. In practice it is impossible to produce completely unbranched polymer molecules on a commercial scale but, by regulating the length and frequency of the side branches, it is possible to produce a variety of different polymer grades with different processing characteristics and in-services properties. The polyethylenes available commercially can be divided into three main groups: low density polyethylene, high-density polyethylene and linear low-density polyethylene. Low-density polyethylene is produced in a high pressure process and contains a high level of side branching with relatively long side chains. High-density polyethylene is produced in a low pressure process and contains fewer side branches. Linear low-density polyethylene contains a large number of side branches but they are very short so that the polymer is able to pack well in the solid state. The chemical structure of the polymer is a repeated series of -CH2-CH2-. Operating conditions: As the data are based on information from 10 plants in 7 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names elsewhere in the tables. Double-counting has been avoided. However, some of the

	emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the year 1992-1993. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Data were supplied from 10 HDPE producers in Austria, Belgium, France, Netherlands, Portugal, Sweden and UK. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Metholodogy report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Results are based on data supplied by 10 HDPE production plants in 7 countries: Austria, Belgium, France, Netherlands, Portugal, Sweden and UK. Their total production was 4 065 000 tonnes.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following general co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', report for Polyethylene resin (HDPE). ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. --- Documented by Caroline Sjöberg and Sofia Haargaard, Volvo Technological Development Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 27 November 2001 ---
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses. 1. Provide APME member companies with information which will highlight potential areas for improving manufacturing processes 2. Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies - Internal company benchmarking - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	APME - Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels Belgium.
Practitioner	Ian Boustead - .
Reviewer	

Applicability	European average data. Results are based on data supplied by 10 production plants in 7 countries: the UK, Austria, Belgium, France, Netherlands, Portugal and Sweden. Their total production was 1,320,000 tonnes. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for polyethylene resin (HDPE) production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data are probably fairly representative for production of polyethylene resin (HDPE) in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission = 3,67 x {mass fraction of carbon in fuel}/{calorific value in MJ/kg} (kg/MJ fuel).

SPINE LCI dataset: Production of polyethylene terephthalate (APME)

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Production of polyethylene terephthalate (APME)
Functional Unit	1 kg of PET
Functional Unit Explanation	PET, Polyethylene terephthalate, is used mainly for polyester fibres. The output of the system is beads of amorphous PET (polyethylene terephtalate) that can be used for fiber spinning, and general purposes.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. Production of polyethylene terephthalate include all major operations from extraction of crude oil and gas to catalytic reforming of naphtha, solvent extraction and fractional distillation. The starting material for the commercial production of PET are ethylene for the production of ethylene glycol and p-xylene for the production of terephthalic acid. Ethylene is produced by cracking natural gas or the naphtha fraction of crude oil. The crackers also produce small quantities of the different isomers of xylene. p-Xylene is used in the production of terephthalic acid because the ´straight´ structure of this isomer is best suited to linear polymers. In practice there are two separate routes used in the production of PET precursors. The first

	method oxidises p-xylene to terephthalic acid which is then purified. This purified terephthalic acid is then reacted with ethylene glycol to produce bishydroxyethyl terephthalate with water as a by-product. The alternative route oxidises p-xylene to terephthalic acid but then reacts the acid immediately with methanol to produce dimethyl terephtalate (DMT). When DMT is is reacted with ethylene glycol, the result is again bishydroxyethyl terephtalate but the by-product is now methanol, which can be recovered and reused. The monomer produced by either route is then polymerised in the liquid phase to amorphous polyethylene terephtalat. In addition to the mentioned sub-processes, the following major processes are included: Crude oil extraction and delivery; oil refining for naphtha (fractional distillation); natural gas extraction, processing and deliver; coal mining and delivery. Also electricity production and production of other raw materials have been included on a cradle to gate basis, i.e. all materials and energies have been tracked back to the extraction of raw materials from the earth. Operating conditions: As the data are based on information from 10 plants in 4 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. For raw materials, inputs as listed from APME, have been reocorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the year 1992-1993. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Results are based on data supplied by 5 polyethylene production plants in 3 countries: Germany, Netherlands and UK. Their total production was 400,000 tonnes. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Metholodogy report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Data were supplied from 5 producers in UK, Netherlands and Germany.

Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following general co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

Date Conceived	1993
Data Type	Derived, mixed
Represents	
Method	European average data. Results are based on data supplied by 5 polyethylene production plants in 3 countries: Germany, Netherlands and UK. Their total production was 400,000 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstram raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. Data from APMEs website www.lca.apme.org have been downloaded as exe-files. The files are opened and imported into Microsoft Excel. Further, the data from MS Excel is exported to a MS Access database.
Literature Reference	APME, Association of Plastics Manufacturers in Europe, website: http://lca.apme.org/reports /htm/alphabetical.htm APME, PET amorphous, prod, 1 kg
Notes	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature used by CPM (CPM 2000:2) The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New names: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', report for PET. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. -- Documented by Caroline Sjöberg and Sofia Haargaard, Volvo Technological Development Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 5 September 2001 --
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses. 1. Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2. Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies - Internal company benchmarking - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	APME - Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels Belgium.

Practitioner	Boustead, Ian - .
Reviewer	-
Applicability	European average data. Data were supplied from 5 producers in UK, Netherlands and Germany. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for PET production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data are probably fairly representative for production of PET in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO_2 emission. CO_2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO_2 emission = 3,67 x {mass fraction of carbon in fuel}/{calorific value in MJ/kg} (kg/MJ fuel).

SPINE LCI dataset: Production of polymethyl methacrylate (APME)

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Production of polymethyl methacrylate (APME)
Functional Unit	1 kg of PMMA
Functional Unit Explanation	Polymethyl methacrylate (PMMA) is a transparent, colourless, thermoplastic polymer. The structure of the polymer solid gives PMMA a distinctive optical clarity. Typical uses for PMMA are baths, sinks and showers, illuminated signs, glazing, motor vehicle rear lights, medical uses such as intra-ocular lenses, contact lenses and implants.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. Production of PMMA include all major operations from extraction of crude oil and gas to catalytic reforming of naphtha, solvent extraction and fractional distillation. The production route of PMMA requires the production of a significant number of intermediates. Essentially the process produce acetone cyanohydrin which is then converted to methyl methacrylate. The monomer may be polymerised to produce beads which can then be extruded, or the monomer may be directly polymerised as in the production of cast sheet. There are a number of different routes to acetone but the most commonly used is as a by-product in the manufacture of phenol. Hydrogen cyanide is mainly produced by the reaction of methane (natural gas) with ammonia. A small proportion of hydrogen cyanide,

	however, is obtained as a by-product from acrylonitrile production. Acetone is then reacted with hydrogen cyanide to produce acetone cyanohydrin and this is converted to methyl methacrylate in an acid solution of sulfuric acid. The intermediate, methacrylamide sulphate is not isolated but the spent sulphuric acid from the process is recovered and regenerated for further use. In addition to the mentioned sub-processes, the following major processes are included: Crude oil extraction and delivery; oil refining for naphtha (fractional distillation); natural gas extraction, processing and deliver; coal mining and delivery. Also electricity production and production of other raw materials have been included on a cradle to gate basis, i.e. all materials and energies have been tracked back to the extraction of raw materials from the earth. Operating conditions: As the data are based on information from 10 plants in 4 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the years 1992-1993. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Data were supplied from 5 polymethyl methacryalate producers in France, Italy, Netherlands and Germany. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Metholodogy report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Results are based on data supplied by 5 production plants in 4 countries: France, Italy, Netherlands and Germany. Their total production was 130 000 tonnes.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following general co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their

	calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

Flow Data

General Activity QMetaData

Date Conceived	1992-1993
Data Type	Derived, mixed
Represents	Data were supplied by the five major producers in Europe, producing 130,000 tonnes annually, and are thought to be representative of the current total production in Europe.
Method	European average data. Results are based on data supplied by 5 production plants in 4 countries: France, Italy, Netherlands and Germany. Their total production was 130 000 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstram raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. Data from APMEs website www.lca.apme.org have been downloaded as exe-files. The files are opened and imported into Microsoft Excel. Further, the data from MS Excel is exported to a MS Access database.
Literature Reference	APME, Association of Plastics Manufacturers in Europe, website: http://lca.apme.org/reports/htm/alphabetical.htm
Notes	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature used by CPM (CPM 2000:2) The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New names: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', report for PMMA beads. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. -- Documented by Caroline Sjöberg and Sofia Haargaard, Volvo Technological Development Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 5 September 2001 --
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses. 1. Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2. Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies - Internal company benchmarking - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	APME - Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels Belgium.
Practitioner	Boustead, Ian - .

Reviewer	-
Applicability	European average data. Data were supplied by the five major producers in Europe, producing 130,000 tonnes annually, and are thought to be representative of the current total production in Europe. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for PMMA beads production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data are probably fairly representative for production of PMMA beads in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission = 3,67 x {mass fraction of carbon in fuel}/{calorific value in MJ/kg} (kg/MJ fuel).

SPINE LCI dataset: Production of polyols (APME)

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Production of polyols (APME)
Functional Unit	1 kg polyols
Functional Unit Explanation	Polyether-polyols are one of the precursors used in the production of polyurethans (PUR). Main areas of use for polyurethans: the furniture and mattress sector, the automotive industry, the consumer sector, the buidling industry and refrigeration engineering. Other applications include coatings, adhesives, sealants, elastomers and fibres.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. Polyether-polyols are one of the precursors used in the production of polyurethans (PUR). The input to the process is crude oil, natural gas and sodium chloride. There are several intermediates in the process.There are three different routes to produce propylene oxide either from benzene, iso-butane or propylene. The input to the last step, the polyol production, is ethylene oxide, propylene oxide, glycerol, other organics and inorganics and sucrose. Operating conditions: As the data are based on information from 12 plants in 4 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity

	production efficiency. For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the year 1995. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Data were supplied from 12 polyol producers in Belgium, Netherlands, Italy and Germany. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Metholodogy report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Results are based on data supplied by 12 polyol production plants in 4 countries: Belgium, Netherlands, Italy and Germany. Their total production was 670 000 tonnes.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following general co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or

	chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

Method	European average data. Results are based on data supplied by 12 polyol production plants in 4 countries: Belgium, Netherlands, Italy and Germany. Their total production was 670 000 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstram raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. Data from APMEs website www.lca.apme.org have been downloaded as exe-files. The files are opened and imported into Microsoft Excel. Further, the data from MS Excel is exported to a MS Access database.
Literature Reference	APME, Association of Plastics Manufacturers in Europe, website: http://lca.apme.org
Notes	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature used by CPM (CPM 2000:2) The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New names: Residue Old name: Co-product New name: By-product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', report for polyols. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. -- Documented by Caroline Sjöberg and Sofia Haargaard, Volvo Technological Development Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 27 November 2001 --
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses. 1. Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2. Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs)

	of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies - Internal company benchmarking - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	APME - Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels Belgium.
Practitioner	Boustead, Ian - .
Reviewer	
Applicability	European average data. Results are based on data supplied by 12 production plants in 4 countries: Belgium, Netherlands, Italy and Germany. Their total production was 670 000 tonnes. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for polyols production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data are probably fairly representative for production of polyols in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission = 3,67 x {mass fraction of carbon in fuel}/{calorific value in MJ/kg} (kg/MJ fuel).

Notes	The following substance names have been changed from the nomenclature used by APME to adapt to nomenclature according to CPM report 2000:2. SPINE LCI dataset: Production of polypropylene (APME)

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Production of polypropylene (APME)
Functional Unit	1 kg of PP
Functional Unit Explanation	The polyolefins are chemically the simplest of the polymers in commercial production. Typical uses for PP are injection moulded products, fibres and filaments and film and sheets. Typical uses for polypropene: - injection moulded products - fibres and filament

	- film and sheet.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. Production of polypropene includes all major operations from extraction of crude oil and gas to catalytic reforming of naphtha, solvent extraction and fractional distillation. PP are usually polymerised by a free radical mechanism whereby an inhibitor opens the double bond of the alkene molecule and attaches itself leaving the other 'open' bond, or radical free to attack a further alkene molecule. The process repeats itself until all of the monomer is used up or, more commonly, the reactive end is itself terminated by a specifically added reactant. In addition to the mentioned sub-processes, the following major processes are included: Crude oil extraction and delivery; oil refining for naphtha (fractional distillation); natural gas extraction, processing and deliver; coal mining and delivery. Also electricity production and production of other raw materials have been included on a cradle to gate basis, i.e. all materials and energies have been tracked back to the extraction of raw materials from the earth. Operating conditions: As the data are based on information from 10 plants in 4 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the year 1992-1993. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Data were supplied from 15 polypropylene producers in Austria, Belgium, Finland, Netherlands, Norway, Portugal, UK. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment

	and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Metholodogy report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Data were supplied from 15 producers in Austria, Belgium, Finland, Netherlands, Norway, Portugal, UK.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following general co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

Flow Data

General Activity QMetaData

Date Conceived	1992-1993
Data Type	Derived, mixed
Represents	
Method	European average data. Results are based on data supplied by 15 PP production plants in 7countries: Austria, Belgium, Finland, Netherlands, Norway, Portugal and UK. Their total production was 1,580,000 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstram raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. Data from APMEs website www.lca.apme.org have been downloaded as exe-files. The files are opened and imported into Microsoft Excel. Further, the data from MS Excel is exported to a MS Access database.
Literature Reference	APME, Association of Plastics Manufacturers in Europe, website: http://lca.apme.org/reports /htm/alphabetical.htm www.lca.apme.org
Notes	For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded. See Notes in Inventory for a list of how the nomenclature for substances used by APME have been translated into the nomenclature used by CPM (CPM 2000:2) The Nomenclature for FlowTypes has in some cases been changed: Old name: Resources New name: Natural resource Old name: Waste New names: Residue Old name: Co-product New name: By-

	product Although the dataset contains a large number of decimals, which usually implies that there is a great accuracy in the data, we are somewhat questioning about this accuracy.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', report for PP. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. -- Documented by Caroline Sjöberg and Sofia Haargaard, Volvo Technological Development Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 5 September 2001 --
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses. 1. Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2. Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies - Internal company benchmarking - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems.

	- Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	APME - Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels Belgium.
Practitioner	Boustead, Ian - .

Applicability	European average data. Data were supplied by the 15 major producers in Austria, Belgium, Finland, Netherlands, Norway, Portugal, UK, producing 1,580,000 tonnes annually. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for PP production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data are probably fairly representative for production of PP in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission = 3,67 x {mass fraction of carbon in fuel}/{calorific value in MJ/kg} (kg/MJ fuel).
Notes	The following substance names have been changed from the nomenclature used by APME to adapt to nomenclature according to CPM report 2000:2. SPINE LCI dataset: Production of polystyrene (APME)

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Production of polystyrene (APME)
Functional Unit	1 kg of PS (General purpose)
Functional Unit Explanation	PS, Polystyrene is a versatile polymer resin used in a wide range of applications - especially in the packaging industry. I Typical uses for polystyrene: - packaging - electronics.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe

Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. Production of polystyrene include all major operations from extraction of crude oil and gas to catalytic reforming of naphtha, solvent extraction and fractional distillation. The production of styrene monomer can be thought of as replacing one of the hydrogen atoms in ethylene by a benzene ring. The monomer is then polymerised, the double bonds in the monomer molecules are opened and neighbouring molecules link together to form a chain. Crude oil refining produces a fraction, naphtha, which contains a mixture of low molecular weight, saturated hydrocarbons of various composition. This is converted into a smaller group of unsaturated hydrocarbons by cracking - a process in which the naphtha is heated to a high temperature in the absence of air, maintained for a short time at this high temperature and then very rapidly cooled back to a low temperature when all the reactions stop and the mix of products is essentially fixed. The resulting mixture is then separated into its constituent components by distillation producing principally ethylene (C_2H_4), propylene (C_3H_6), mixed butenes of general formula (C_4H_8) and a number of other compounds which find uses elsewhere in the petrochemical plant either as feedstocks or fuels. The precise mix of products from cracking are determined by a number of factors such as cracker temperature, residence time and the nature of the feedstock and the operation of a cracker can often be adjusted to produce the required mix of products. Natural gas is also converted into ethylene, propylene, butenes and other products by cracking. Although benzene is usually present in small quantities in crude oil, its direct extraction is usually uneconomic. However, one by product of naphtha cracking is a liquid usually referred to as pyrolysis gasoline which is high in unsaturated aliphatic and aromatic hydrocarbons. The benzene fraction in pyrolysis gasoline can be extracted by repeated distillation and it is thought that about half of all benzene used in Europe is produced in this way. Benzene is also produced directly from naphtha by a process known as catalytic reforming. The basic feedstock is converted into a mixture of products of which the principal components are benzene, toluene and xylene (the process is often referred to as the BTX process). Benzene and other aromatics are isolated in the pure state from the output of the reformer by solvent extraction and fractional distillation. In addition to the mentioned sub-processes, the following major processes are included: Crude oil extraction and delivery; oil refining for naphtha (fractional distillation); natural gas extraction, processing and deliver; coal mining and delivery. Also electricity production and production of other raw materials have been included on a cradle to gate basis, i.e. all materials and energies have been tracked back to the extraction of raw materials from the earth. Operating conditions: As the data are based on information from 10 plants in 4 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the year 1994. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Data were supplied from 15 polystyrene producers in Belgium, France, Germany, Italy, Netherlands, Sweden, UK. For the APME Eco-profiles in general, the coverage of European production varies from 60

	to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Metholodogy report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Data were supplied from 15 producers in Belgium, France, Germany, Italy, Netherlands, Sweden, UK.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following general co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

Flow Data

General Activity QMetaData

Date Conceived	1994
Data Type	Derived, mixed
Represents	
Method	European average data. Results are based on data supplied by 15 polystyrene production plants in 7 countries: Belgium, France, Germany, Italy, Netherlands, Sweden and UK. Their total production was 810 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstram raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific

	values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. Data from APMEs website www.lca.apme.org have been downloaded as exe-files. The files are opened and imported into Microsoft Excel. Further, the data from MS Excel is exported to a MS Access database.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', report for PS (General purpose). ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. -- Documented by Caroline Sjöberg and Sofia Haargaard, Volvo Technological Development Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 5 September 2001 --

Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses. 1. Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2. Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies - Internal company benchmarking - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	APME - Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels Belgium.
Practitioner	Boustead, Ian - .
Reviewer	-
Applicability	European average data. Data were supplied from 15 producers in Belgium, France, Germany, Italy, Netherlands, Sweden, UK. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for PS (General purpose) production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data are probably fairly representative for production of PS (General purpose) in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45,0 MJ/kg for crude oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur. The

	following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission = 3,67 x {mass fraction of carbon in fuel}/{calorific value in MJ/kg} (kg/MJ fuel).

SPINE LCI dataset: Production of polyvinyl chloride, emulsion polymerised (APME)

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System

Name	Production of polyvinyl chloride, emulsion polymerised (APME)
Functional Unit	1 kg of PVC (e)
Functional Unit Explanation	PVC (e) - (Poly Vinyl Chloride, emulsion polymerised) is a chlorinated hydrocarbon polymer. The polymer is produced from vinyl chloride by a process essentially similar to that used in the production of polyethylene, polypropylene and polystyrene. Emulsion polymerised PVC is mainly used for coating applications such as PVC coated fabrics.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	The information given below comprises all available information in the datasheet from APME, from which this data set is acquired. The PVC polymer is produced from vinyl chloride by a process where the double bond in the vinyl chloride is opened and neighbouring molecules combine with each other to produce a long chain molecule. The starting raw material for PVC are crude oil and natural gas for the hydrocarbon part of the molecule and naturally occuring sodium chloride (and to a lesser extent, potassium chloride) for the chlorine part. The hydrocarbon feedstocks are converted by cracking to ethylene (ethene). The sodium chloride is electrolysed as an aqueous solution to produce chlorine with sodium hydroxide and hydrogen as co-products. The ethylene and chlorine are reacted to produce 1,2-dichloroethane (ethylene dichloride) (reaction 1). The 1,2-dichloroethane is then decomposed by heating in a high temperature furnace (cracking) when it produces vinyl chloride and hydrogen chloride (reaction 2). If the process were stopped at this stage, it is clear that 50% of the input of chlorine would be lost from the system and, unless there were a sufficient demand for hydrogen chloride, this would represent a significant loss of raw materials. In practice, however, the hydrogen chloride from reaction (2) is reacted with further ethylene in the presence of oxygen (a reaction known as oxychlorination), to produce further 1,2-dichloroethane (reaction 3). The dichloroethane is now decomposed according to reaction (2). By matching the direct and oxychlorination steps, the overall reaction adds reaction (1), (2) and (3). The chlorine is now completely used by the overall process. For raw materials, inputs as listed from APME, have been recorded in this data set. For ''Fuels & Feedstocks'', all fueltypes have been included. In addition, ''Total Energy'' for ''Hydro'', ''Nuclear'' and ''Recovered Energy'' fueltypes from ''Primary Fuels & Feedstocks'' have been included. ''Recovered Energy'' has been recorded in this data set as an outflow with positiv sign. For ''Water Use'' the total amount has been recorded.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available''. Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have been estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under the specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	Data refer to the year 1992-1993. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Data were supplied from 5 polyvinyl chloride producers in France, Germany, UK. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates (including toluene). For some intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides than plants in other countries.

Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included). - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0,01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Metholodogy report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass. European average data. Results are based on data supplied by 5 production plants in 3 countries: France, Germany, UK. Their total production was 510,000 tonnes.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following general co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g. sulphuric acid is used as a drying agent for chlorine, therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity. These allocations are general for data from APME, and only applicable for datasets where the above mentioned processes are included.
Systems Expansions	Not applied.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', report for PVC (e). ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. -- Documented by Caroline Sjöberg and Sofia Haargaard, Volvo Technological Development Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 5 September 2001 --
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as buiding blocks for use in the construction of complete life cycle analyses. 1. Provide APME member companies with information which will highlight potential areas for

	improving manufacturing processes, 2. Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies - Internal company benchmarking - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occured since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	APME - Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels Belgium.
Practitioner	Boustead, Ian - .

Applicability	European average data. Results are based on data supplied by 5 production plants in 3 countries: France, Germany, UK. Their total production was 510,000 tonnes. The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
