Swedish Life Cycle Center Report 2020:07

CPM LCA Database - Life Cycle Inventory Datasets

JOHAN TIVANDER
Division of Environmental
Systems Analysis
Department of Technology
Management and Economics
Chalmers University of
Technology

The CPM LCA Database – Life Cycle Inventory Datasets.

This report contains all 748 complete LCI datasets in the CPM LCA Database as published in 2020-11-20.

Contents:

For information about the database please refer to the Swedish Life Cycle Center, lifecyclecenter.se.

Table 1. List of all life cycle inventory datasets in the CPM LCA Database as of 2020-11-20 in allphabetical order.

#	Process name	Technical scope	Product or service	Date Completed	CPM Quality
1	″Other″ electronic components assembly	Gate to gate	Other electronic components	2000-03-15	A
2	Air-and-water air conditioning system. ESA-DBP	Cradle to gate	Treatment and the distribution of totally 34 m3/s airflow for 17000 m2 landscape office area, when the cooling loads are totally 1189 MWh/year.	2007	S
3	Airbag's can production. Autoliv ESA-DBP	Gate to gate	Can	2010-07-08	S
4	Airbag's cushion manufacturing. Autoliv ESA-DBP	Gate to gate	Cushion	2010-07-08	S
5	Airbag's igniter granules manufacturing. Autoliv ESA-DBP	Unit operation	Igniter granules	2010-07-08	S
6	Airbag's inflator assembly. Autoliv ESA-DBP	Unit operation	Inflator	2010-07-08	S
7	Airbag's initiator assembly. Autoliv ESA-DBP	Unit operation	Initiator	2010-07-08	S
8	Airbag's label manufacturing. Autoliv ESA-DBP	Gate to gate	Label	2010-07-08	S
9	Airbag's nut manufacturing. Autoliv ESA-DBP	Gate to gate	Nut	2010-07-08	S
10	Airbag's shunt ring. Autoliv ESA-DBP	Gate to gate	Shunt ring	2010-07-08	S
11	Air-conditioning system. ESA-DBP	Cradle to gate	Air-conditioning system which conditions and distributes a variable airflow volume (VAV) of a max. 5 m3/s	2007	S
12	All-air air handling unit with a cooling coil and vapour compression chiller with a refrigerant. ESA	Cradle to grave	″One air handling unit, which distributes a constant airflow volume (CAV) of 4.8 m3/s 24h a day for 15 years.″	2007	S
13	All-air desiccant cooling air handling unit. ESA-DBP	Cradle to grave	″One air handling unit, which distributes a constant airflow volume (CAV) of 4.8 m3/s 24h a day for 15 years.″	2007	S
14	Aluminium recycling by refiners	Gate to gate	Aluminium ingot	2002-05-07	S
15	Anaerobic digestion of biological household waste. ESA-DBP	Gate to gate	Bio fertilizer; total Nitrogen Biogas	2006-2007	S
16	Australia, electricity generation mix 1998	Unit operation	Electricity	2001-01-31	A
17	Austria, electricity generation mix 1998	Unit operation	Electricity	2001-01-31	A
18	Belgium, electricity generation mix 1998	Unit operation	Electricity	2001-01-31	A
19	Biofuel electricity energy system, EPD-version	Cradle to grave	Electricity	1996	S
20	Biogas from household waste, cradle-to-gate, no allocation - f3 fuels	Cradle to gate	Biogas from household waste	2013-11-30	A
21	Biogas from household waste, cradle-to-gate, system expansion, impact categories only - f3 fuels	Cradle to gate	Biogas from household waste	2013-11-30	A
22	Biogas from industrial waste, cradle-to-gate, no allocation - f3 fuels	Cradle to gate	Biogas from industrial waste	2013-11-30	A
23	Biogas from industrial waste, cradle-to-gate, system expansion, impact categories only - f3 fuels	Cradle to gate	Biogas from industrial waste	2013-11-30	A
24	Biogas from sewage sludge, cradle-to-gate, no allocation - f3 fuels	Cradle to gate	Biogas from sewage sludge	2013-11-30	A
25	Biogas from sewage sludge, cradle-to-gate, system expansion, impact categories only - f3 fuels	Cradle to gate	Biogas from sewage sludge	2013-11-30	A
26	Biogas from sugar beets, cradle-to-gate, no allocation - f3 fuels	Cradle to gate	Biogas from sugar beets	2013-11-30	A
27	Biogas from sugar beets, cradle-to-gate, system expansion, impact categories only - f3 fuels	Cradle to gate	Biogas from sugar beets	2013-11-30	A
28	Biogasification of solid municipal waste	Gate to gate	Compost	2002-08-14	S

29	Bore-hole based air-conditioning system. ESA-DBP	Cradle to grave	Air-conditioning system which conditions and distributes a variable airflow volume (VAV) of a max. 5 m3/s	2007	S
30	Cable assembly	Gate to gate	Cables	2000-03-08	S
31	Canada, electricity generation mix 1998	Unit operation	Electricity	2001-01-31	A
32	Capacitor for hole mounting assembly	Gate to gate	Capacitor for hole mounting	2000-03-15	S
33	Capacitor for surface mounting assembly	Gate to gate	Capacitor for surface mounting	2000-03-08	S
34	Cardboard production (MDF based). ESA-DBP	Gate to gate	Cardboard	1997	A
35	Cargo vessel, medium-sized (8´-2´ dwt)	Gate to gate	Cargo	1998 08	S
36	Cargo vessel, small (<2´dwt)	Gate to gate	Cargo	1998 08	S
37	Cargo vessels, large (>8´ dwt)	Gate to gate	Cargo	1998 08	S
38	Cast iron production. ESA-DBP	Gate to gate	Cast iron	1996	S
39	Casting of iron, type V10	Unit operation	Cast iron	02-12-31	S
40	CBG combustion in heavy duty truck or bus, spark ignition engine, Euro V, tank-to-wheel, f3 fuels	Gate to grave	1 MJ	2013-11-30	A
41	CBG combustion in heavy duty truck or bus, spark ignition engine, Euro VI, tank-to-wheel, f3 fuels	Gate to grave	1 MJ	2013-11-30	A
42	Cement production	Cradle to gate	Cement	1997-05-01	S
43	Clay roof tile manufacturing. ESA-DBP	Cradle to gate	Tiles	1993	A
44	Cleaning and blastering of cast iron	Unit operation	Cast iron	02-12-31	S
45	Cleaning of bearing roller	Unit operation	roller	2002-12-12	S
46	Cleansing of glass containers	Gate to gate	Glass container	1991-01-01	U
47	Cleansing of juice bottles	Gate to gate	Juice bottles	1991-01-01	U
48	Clearing of young forest	Gate to gate	Young forest area	1998-02-13	A
49	CNG combustion in heavy duty truck or bus, spark ignition engine, Euro V, tank-to-wheel, f3 fuels	Gate to grave	1 MJ	2013-11-30	A
50	CNG combustion in heavy duty truck or bus, spark ignition engine, Euro VI, tank-to-wheel, f3 fuels	Gate to grave	1 MJ	2013-11-30	A
51	Coal fired plant for heat and power production - Large plant	Gate to gate	Heat	2000-07-07	S
52	Coal mining and cleaning. ESA-DBP	Gate to gate	Coal	1996	S
53	Coarse mortar production	Gate to gate	Coarse mortar	1996-10-01	A
54	Coastal shipping	Unit operation	Cargo	1994-04-01	S
55	Cold reducing of steel sheets	Unit operation	Cold reduced steel sheet	02-12-31	S
56	Collection area driving, with diesel driven waste collection vehicle. ESA-DBP	Unit operation	1 h of collection area driving	2005	A
57	Collection area driving, with gas driven waste collection vehicle. ESA-DBP	Unit operation	1 h of collection area driving	2005	A
58	Collection area driving, with hybrid (gas-electric driven) waste collection vehicle. ESA-DBP	Unit operation	1 h of collection area driving	2005	A
59	Collection stop, with diesel driven waste collection vehicle. ESA-DBP	Unit operation	1 h of collection stop	2005	A
60	Collection stop, with gas driven waste collection vehicle. ESA-DBP	Unit operation	1 h of collection stop	2005	A
61	Collection stop, with hybrid (gas-electric driven) waste collection vehicle. ESA-DBP	Unit operation	1 h of collection stop	2005	A
62	Combined heat and power plant (CFB-KVV) with support systems	Cradle to gate	Electricity	1996-12-01	S
63	Combined heat and power plant (GCC-KVV) with support systems	Cradle to gate	Electricity	1996-12-01	S
64	Combustion of bio fuel	Gate to gate	1 MJ	1991	U
65	Combustion of coal	Gate to gate	1 MJ	1991	U

66	Combustion of natural gas	Gate to gate	1 MJ	1991	U
67	Combustion of oil	Gate to gate	1 MJ	1991	U
68	Combustion of waste	Gate to grave	Thermal energy Electricity	1999-04-19	S
69	Combustion of waste oil	Unit operation	84 kg oil	2002-12-18	S
70	Combustion of waste to generate heat and electricity	Gate to gate	District heating Electricity	1996-03-01	S
71	Composting of solid municipal waste	Gate to gate	Compost	2002-08-14	S
72	Connector assembly	Gate to gate	Connectors	2000-03-09	S
73	Construction of liquid composting batch system. ESA-DBP	Gate to gate	person·year	1997	S
74	Construction of liquid composting continous system. ESA-DBP	Gate to gate	person·year	1997	S
75	Construction of small-scale waste water treatment plant. ESA-DBP	Gate to gate	person·year	1997	S
76	Converting waste-oil into fuel oil AGGR	Gate to gate	Electricity/Heat Converted fuel oil	1999	S
77	Copper alloy casting of block metal from scrap	Gate to gate	1 kg block metal	1995	U
78	Copper casting and drawing to 0.06mm wire	Gate to gate	1 kg 0,06 mm copper wire	1995	U
79	Copper casting and drawing to 0.6mm wire	Gate to gate	1 kg of 0.6 mm copper wire	1995	U
80	Copper casting and drawing to 8mm wire	Gate to gate	1 kg of 8mm copper wire	1995	U
81	Copper casting, drawing and laquering to 0.6mm wire	Gate to gate	1 kg 0,6 mm laquer coated copper wire	1995	U
82	Copper casting, drawing and polmer coating to 0.6mm wire	Gate to gate	1 kg 0,6 mm polymer coated copper wire	1995	U
83	Copper continuous casting	Gate to gate	1 kg of cast copper	1995	U
84	Copper extrusion and drawing to profiles	Gate to gate	1 kg extruded copper profiles	1995	U
85	Copper extrusion and drawing to tubes	Gate to gate	1 kg of extruded and drawn copper tubes	1995	U
86	Copper ore concentrate preparation and delivery	Cradle to gate	copper ore concentrate	1998	A
87	Copper ore mining	Cradle to gate	Copper ore	1998	A
88	Copper ore mining and concentration	Cradle to gate	1 kg copper in concentrate	1995	U
89	Copper production	Cradle to gate	kg	1996-05-01	S
90	Copper rolling to strips	Gate to gate	1 kg of rolled copper strip	1995	U
91	Copper skew rolling, pilgering and drawing to tubes	Gate to gate	1 kg of pilgered copper tubes	1995	U
92	Cotton (conventional) fibres production. ESA-DBP	Gate to gate	cotton fibres	2004	S
93	Cotton covering of sofa. ESA-DBP	Cradle to grave	″The functional unit was: surface covering of a 3-seat sofa for private use during 10 years.″ For cotton fabric it is 4.99 kg per sofa.	2004	S
94	Crushing and cleaning of broken glass	Gate to gate	Crushed, cleaned glass	1991-01-01	U
95	Cultivation and felling of trees for papermaking. ESA-DBP	Cradle to gate	Birchwood	1997	A
96	CuNi10Fe extrusion and drawing of tubes	Gate to gate	1 kg CuNi10Fe tubes	1995	U
97	CuNi10Fe extrusion and pilgering of tubes	Gate to gate	1 kg CuNi10Fe tubes	1995	U
98	CuNi10Fe semicontinuous casting	Gate to gate	1 kg of cast CuNi10Fe	1995	U
99	CuSn6 casting and drawing to wire	Gate to gate	1 kg CuSn6 wire	1995	U
100	CuSn6 casting and rolling to strips	Gate to gate	1 kg CuSn6 strips	1995	U
101	CuSn6 continuous casting	Gate to gate	1 kg cast CuSn6	1995	U
102	Cutting of steel bars (117x147 mm)	Unit operation	Cut steel bar	02-12-31	S
103	CuZn37 casting and drawing to wire	Gate to gate	1 kg CuZn37 wire	1995	U
104	CuZn37 casting and extruding over core to tubes	Gate to gate	1 kg CuZn37 tubes	1995	U
105	CuZn37 casting and rolling to strips	Gate to gate	1 kg CuZn37 strips	1995	U
106	CuZn37 continuous casting	Gate to gate	1 kg cast CuZn37	1995	U

107	CuZn37Pb chill casting	Gate to gate	1 kg cast CuZn37Pb	1995	U
108	CuZn39Pb2 casting and pressing to rods	Gate to gate	1 kg CuZn39Pb2 bars	1995	U
109	Czech Republic, electricity generation mix 1998	Unit operation	Electricity	2001-01-31	A
110	Delivery van, distribution, diesel	Gate to gate	Cargo	1998 - 08	S
111	Delivery van, distribution, petrol	Gate to gate	Cargo	1998 - 08	S
112	Denmark, electricity generation mix 1998	Unit operation	Electricity	2001-01-31	A
113	De-watering of water-sludge	Gate to gate	1 m3 of recieved water-sludge from Reci Industri Halmstad.	1999-04-19	S
114	Diesel combustion	Gate to gate	Diesel energy	1991-01-01	U
115	Diesel driven freight train, future	Unit operation	Cargo	1997-11-19	S
116	Diesel driven freight train, T44 engine	Unit operation	Cargo	1997-11-19	S
117	Diesel EN590, EU-15, cradle-to-gate, energy allocation - f3 fuels	Cradle to gate	Diesel EN590	2013-11-30	A
118	Diesel engine, Euro 0	Unit operation	Mechanical work	1997-11-19	S
119	Diesel engine, Euro 1	Unit operation	Mechanical work	1997-11-19	S
120	Diesel engine, Euro 2	Unit operation	Mechanical work	1997-11-19	S
121	Diesel engine, future	Unit operation	Mechanical work	1997-11-19	S
122	Diesel MK1, cradle-to-gate, energy allocation - f3 fuels	Cradle to gate	Diesel MK1	2013-11-30	A
123	Diesel production	Cradle to gate	Diesel	1996-01-01	U
124	Diesel propulsed train	Unit operation	Cargo	1999 - 11	S
125	Dioctyl phthalate (DOP) production. ESA-DBP	Gate to gate	dioctyl phthalate	1992	A
126	Dioctyl phthalate (DOP) production. ESA-DBP	Gate to gate	DOP	1997	A
127	Diode wafer production and assembly	Gate to gate	Diodes	2000-03-02	S
128	Dismounting of bearing	Unit operation	1.2 ton bearing	2002-12-18	A
129	Disposal of polyethylene to landfill.	Gate to grave	1000 kg of polyethylene	2003-01-10	S
130	Dry wood chips fired plant for heat and power production - Large plant	Gate to gate	Heat	1999-08-30	S
131	ED95 - Sugar cane, cradle-to-gate, energy allocation, impact categories only - f3 fuels	Cradle to gate	ED95 from sugar cane	2013-11-30	A
132	ED95 - Sugar cane, cradle-to-gate, system expansion, impact categories only - f3 fuels	Cradle to gate	ED95 from sugar cane	2013-11-30	A
133	ED95 - Wheat, cradle-to-gate, energy allocation - f3 fuels	Cradle to gate	ED95 from wheat	2013-11-30	A
134	ED95 - Wheat, cradle-to-gate, system expansion, impact categories only - f3 fuels	Cradle to gate	ED95 from wheat	2013-11-30	A
135	ED95 combustion in heavy duty truck or bus with a diesel engine, Euro V, tank-to-wheel, f3 fuels	Gate to grave	1 MJ	2013-11-30	A
136	ED95 combustion in heavy duty truck or bus with a diesel engine, Euro VI, tank-to-wheel, f3 fuels	Gate to grave	1 MJ	2013-11-30	A
137	Electric freight train, waggon load	Gate to gate	Cargo	99 - 11 -	S
138	Electric freight train, waggon load, including electricity production	Gate to gate	Cargo	99 - 11 -	S
139	Electrically driven combi train, future	Unit operation	Cargo	1997-11-19	S
140	Electrically driven combi train, RC engine	Unit operation	Cargo	1997-11-19	S
141	Electrically driven freight train 230 metres, future	Unit operation	Cargo	1997-11-19	S
142	Electrically driven freight train 230 metres, RC engine	Unit operation	Cargo	1997-11-19	S

143	Electrically driven freight train 700 metres, future	Unit operation	Cargo	1997-11-19	S
144	Electrically driven freight train 700 metres, RC engine	Unit operation	Cargo	1997-11-19	S
145	Electrically driven Intermodal train, RC engine	Gate to gate	Cargo	99 - 11 -	S
146	Electrically driven intermodal train, RC engine, including electricity production	Unit operation	Cargo	99 - 11 -	S
147	Electrically driven system train (Circuit-working), RC engine	Unit operation	Cargo	99 - 11 -	S
148	Electrically driven system train (Circuit-working), RC engine, including electricity production	Unit operation	Cargo	99 - 11 -	S
149	Electrically driven system train, future	Unit operation	Cargo	1997-11-19	S
150	Electrically driven system train, RC engine	Unit operation	Cargo	1997-11-19	S
151	Electricity production and distribution - India - Regionalized	Gate to gate	Electricity	2016-12-12	
152	Electronic Control Unit's aluminium capacitor manufacturing. Autoliv ESA-DBP	Gate to gate	Aluminium capacitor	2010-08-05	U
153	Electronic Control Unit's electronic connector manufacturing. Autoliv ESA-DBP	Gate to gate	Connector	2010-08-05	U
154	Electronic Control Unit's housing manufacturing. Autoliv ESA-DBP	Gate to gate	Housing	2010-08-05	U
155	Electronic Control Unit's inductor choke manufacturing. Autoliv ESA-DBP	Gate to gate	Inductor choke	2010-08-05	U
156	Electronic Control Unit's integrated circuit ASIC manufacturing. Autoliv ESA-DBP	Gate to gate	Integrated circuit ASIC	2010-08-05	U
157	Electronic Control Unit's integrated circuit comparator manufacturing. Autoliv ESA-DBP	Gate to gate	Integrated circuit comparator	2010-08-05	U
158	Electronic Control Unit's integrated circuit interface manufacturing. Autoliv ESA-DBP	Gate to gate	Integrated circuit interface	2010-08-05	U
159	Electronic Control Unit's integrated circuit MCU/memory manufacturing. Autoliv ESA-DBP	Gate to gate	Integrated circuit MCU	2010-08-05	U
160	Electronic Control Unit's label manufacturing. Autoliv ESA-DBP	Gate to gate	Label	2010-08-05	U
161	Electronic Control Unit's MEMS based sensor manufacturing. Autoliv ESA-DBP	Gate to gate	Sensor	2010-08-05	U
162	Electronic Control Unit's Printed Circuit Board (PCB) base manufacturing. Autoliv ESA-DBP	Gate to gate	PCB board	2010-08-05	U
163	Electronic Control Unit's rectifier diode manufacturing. Autoliv ESA-DBP	Gate to gate	Diode rectifier	2010-08-05	U
164	Electronic Control Unit's resistor manufacturing. Autoliv ESA-DBP	Gate to gate	Resistor thick film	2010-08-05	U
165	Electronic Control Unit's resonator manufacturing. Autoliv ESA-DBP	Gate to gate	Resonator	2010-08-05	U
166	Electronic Control Unit's Schottky diode manufacturing. Autoliv ESA-DBP	Gate to gate	Schottky diode	2010-08-05	U
167	Electronic Control Unit's screw manufacturing. Autoliv ESA-DBP	Gate to gate	Screw	2010-08-05	U
168	Electronic Control Unit's signal diode manufacturing. Autoliv ESA-DBP	Gate to gate	Signal diode	2010-08-05	U
169	Electronic Control Unit's transistor manufacturing. Autoliv ESA-DBP	Gate to gate	Transistor	2010-08-05	U
170	Electronic Control Unit's TVS diode manufacturing. Autoliv ESA-DBP	Gate to gate	TVS diode	2010-08-05	U
171	Ethanol from sugar beets, cradle-to-gate, energy allocation - f3 fuels	Cradle to gate	Ethanol from sugar beets	2013-11-30	A
172	Ethanol from sugar beets, cradle-to-gate, system expansion, impact categories only - f3 fuels	Cradle to gate	Ethanol from sugar beets	2013-11-30	A

173	Ethanol from sugar cane, cradle-to-gate, energy allocation, impact categories only - f3 fuels	Cradle to gate	Ethanol from sugar cane	2013-11-30	A
174	Ethanol from sugar cane, cradle-to-gate, system expansion, impact categories only - f3 fuels	Cradle to gate	Ethanol from sugar cane	2013-11-30	A
175	Ethanol from wheat, cradle-to-gate, energy allocation - f3 fuels	Cradle to gate	Ethanol from wheat	2013-11-30	A
176	Ethanol from wheat, cradle-to-gate, system expansion, impact categories only - f3 fuels	Cradle to gate	Ethanol from wheat	2013-11-30	A
177	Ethylene production from cane based ethanol. ESA-DBP	Gate to gate	Ethylene	2009	S
178	European average production of sodium carbonate (Solvay process)	Gate to gate	Sodium carbonate	2003-03-10	S
179	European Union, electricity generation mix 1998	Unit operation	Electricity	2001-01-31	A
180	Exterior coating (Swedish red paint) maintenance. ESA-DBP	Gate to gate	Maintenance	1999	A
181	Extraction and beneficiation of rock phosphate	Other	Rock phosphate	99-01-25	A
182	Extraction and grinding of dolomite	Other	Dolomite	1999-01-25	A
183	Extraction and processing of natural gas (NG). ESA-DBP	Cradle to gate	1 Nm3 processed natural gas	1999	A
184	Extraction of crude oil	Cradle to gate	Crude oil	1991	U
185	Extraction of crude oil and gas	Cradle to gate	Crude oil Gas	1994	S
186	Extraction of dolomite	Cradle to gate	Dolomite	1991-01-01	U
187	Extraction of dolomite	Other	Dolomite	1999-01-25	A
188	Extraction of feldspar	Cradle to gate	Feldspar	1991-01-01	U
189	Extraction of lime	Cradle to gate	Lime	1991-01-01	U
190	Extraction of Portland soda	Cradle to gate	Portland soda	1991-01-01	U
191	Extraction of sand	Cradle to gate	Sand	1991-01-01	U
192	Extraction of sulphur and production of sulphuric acid	Other	H2SO4	99-01-25	A
193	Extraction to ABS APME	Cradle to gate	ABS	1999	S
194	Extraction to polycarbonate APME	Cradle to gate	Polycarbonate	1997	A
195	Extraction to polyethylene all grades APME	Cradle to gate	Polyethylene all grades	1993	A
196	Extraction to polyethylene HD APME	Cradle to gate	Polyethylene HD	1999	S
197	Extraction to polyethylene LD APME	Cradle to gate	Polyethylene LD	1999	S
198	Extraction to polyethylene linear LD APME	Cradle to gate	Polyethylene LD	1999	S
199	Extraction to SAN APME	Cradle to gate	SAN	1999	S
200	Extraction to toluene APME	Cradle to gate	Toluene	1999	S
201	Extraction to xylene APME	Cradle to gate	Xylene	1999	S
202	Extraction, beneficiation and grinding of kieserite	Other	Kieserite	99-01-25	A
203	Extraction, beneficiation and grinding of potash salt	Other	Potassium chloride	99-01-25	A
204	Fabrication of oil filters	Cradle to gate	Filter Pall HC 8904 FKP 16Z	2002-12-12	S
205	Ferry	Gate to gate	Cargo	1998 08	S
206	Ferry, 700-7000 tonnes	Unit operation	Cargo	1997-11-19	S
207	Ferry, 700-7000 tonnes, future	Unit operation	Cargo	1997-11-19	S
208	Fertilizing in silviculture	Gate to gate	Fertilized forest area	1994-02-24	A

209	Final felling	Gate to gate	Final felling softwood Forest land	1998-02-13	A
210	Finland, electricity generation mix 1998	Unit operation	Electricity	2001-01-31	A
211	Flame laminate treatment of textiles	Gate to gate	Laminated textile	1997-03-01	A

428	Portugal, electricity generation mix 1998	Unit operation	Electricity	2001-01-31	A

429	Potentiometer assembly	Gate to gate	Potentiometers	2000-02-22	S
430	Preparation and anti-corrosive treatment of construction steel	Gate to gate	Blasted and painted construction steel	1997-03-01	A
431	Pre-stressing wire production	Gate to gate	Prestressing wire	1996-10-01	A
432	Pre-treatment of biowaste	Gate to gate	biowaste to biogasification biowaste to composting	2002-08-14	S
433	Primary aluminium production	Cradle to gate	Aluminium ingot	2002-05-07	S
434	Printed board assembly	Gate to gate	Printed boards	2000-03-07	S
435	Printing works	Gate to gate	Printed paper	1997-03-01	A
436	Processing of waste-oil into fuel oil	Gate to gate	Converted fuel oil	1998-04-17	S
437	Production and assemblage of parts to the engineering industry	Gate to gate	1996	1996-03-01	U
438	Production and refining of metal components	Gate to gate	Components of steel	1997-03-01	U
439	Production of 0,005-0,02 mm double-rolled aluminium foil	Gate to gate	Aluminium foil (0,005-0,02 mm)	2002-05-06	S
440	Production of 0,02-0,2 mm single-rolled aluminium foil	Gate to gate	Aluminium foil (0,02-0,2 mm)	2002-05-07	S
441	Production of a Corrugated Board Box (182*62*182)	Gate to gate	Corrugated Board Box	2000-01-18	S
442	Production of Alkyl Polyglucosides (APG) from coconut oil	Cradle to gate	Alcyl Polyglucosides	95-01-01	A
443	Production of ammonia	Gate to gate	Ammonia	99-01-25	A
444	Production of ammonium nitrate	Gate to gate	Ammonium nitrate	1999-01-25	A
445	Production of bearing rings	Cradle to gate	Bearing rings	02-12-31	S
446	Production of bearing rollers (à 9,2 kg)	Cradle to gate	bearing roller	02-12-31	A
447	Production of Bearing Steel	Cradle to gate	Steel ingot	2000-01-17	S
448	Production of beef. ESA-DBP	Gate to gate	Beef	2005	S
449	Production of benzene (APME)	Cradle to gate	Benzene	1999	S
450	Production of Blister Copper	Cradle to gate	Blister copper	1998	A
451	Production of brass cages used for spherical roller bearings	Gate to gate	Brass cage	02-12-31	S
452	Production of butadiene	Cradle to gate	1 kg butadiene	1999-01-01	S
453	Production of cameras, magazines and accessories	Gate to gate	Camera	1996-03-01	A
454	Production of CAN fertiliser	Gate to gate	Nitrogen fertiliser	1999-01-25	A
455	Production of CAN fertiliser AGGR	Cradle to gate	Nitrogen fertiliser	1999	A
456	Production of clean bearing steel	Gate to gate	Ingot Mould	02-12-31	S
457	Production of cooling fluid, R134a	Cradle to gate	R134a	1995	A
458	Production of Copper Anodes	Cradle to gate	Copper Anode	1998	A
459	Production of copypaper. ESA-DBP	Other	Copypaper	1997	S
460	Production of dimethylether from energy forest	Gate to gate	Dimethylethyl	1996	A
461	Production of Dowel Adhesive PVAC 3370	Cradle to gate	PVAc 3370	2000-03-06	A
462	Production of energy forest	Gate to gate	Willow	1997	A
463	Production of EPDM	Cradle to gate	EPDM	2001-03-01	A
464	Production of ethyl alcohol using energy forest and the CASH-method	Gate to gate	Ethanol Lignin	1996	A
465	Production of ethyl alcohol using energy forest and the CHAP-method	Gate to gate	Ethanol	1997	A
466	Production of ethyl alcohol using energy forest and the enzyme-method	Gate to gate	Ethanol Lignin	1996	A
467	Production of extruded aluminium profiles	Gate to gate	Extruded aluminium profile	2002-05-07	S
468	Production of guide rings used for spherical roller bearings	Cradle to gate	Guide ring	02-12-31	S

469	Production of Hardener 2542 for melamine urea formaldehyde resins 1241 and 1242 production	Cradle to gate	Hardener 2542	2003-03-26	A
470	Production of Hardener 2545 for urea formaldehyde resins	Cradle to gate	Hardener 2545	2000-03-10	A
471	Production of Hardener 2580 for urea formaldehyde resins	Cradle to gate	Hardener 2580	2000-03-10	A
472	Production of high-density polyethylene	Gate to gate	HDPE	1991	U
473	Production of hot mix for asphalt pavement.	Cradle to gate	Hot mix	2001-02-09	S
474	Production of hot rolled steel rings	Gate to gate	Hot rolled steel rings	02-12-31	S
475	Production of hydrogen (cracker) (APME)	Cradle to gate	Hydrogen (cracker)	1999	S
476	Production of injection moulding	Gate to gate	Injection moulding	1991	U
477	Production of insulation glass wool	Gate to gate	Glass wool	2002-03-03	S
478	Production of insulation rock wool	Gate to gate	Rock wool	2000-04-01	S
479	Production of iron oxide	Cradle to gate	Iron oxide	1993	U
480	Production of iron oxide yellow colorant containing Bermodol SPS 2532	Cradle to gate	Iron oxide yellow colorant containing Be	2004-04-01	A
481	Production of iron oxide yellow colorant containing Berol 09	Cradle to gate	Iron oxide yellow colorant containing Be	2004-04-01	A
482	Production of Iron Powder	Cradle to gate	Steel powder	2000-01-24	A
483	Production of Kraftliner	Gate to gate	Kraftliner	2000-01-18	S
484	Production of latex rubber	Cradle to gate	Latex rubber	1994-02-01	A
485	Production of Linear Alkylbenzene Sulphonates (LAS)	Cradle to gate	Linear Alkylbenzene Sulphonates	1995-04-01	A
486	Production of linoleum	Gate to gate	Linoleum	1994	U
487	Production of linseed oil	Cradle to gate	Linseed oil Linseed cake	1994	U
488	Production of linseed oil in Sweden	Cradle to gate	Linseed oil Linseed cake	1994	U
489	Production of low-density polyethylene	Gate to gate	LDPE	1991	U
490	Production of lubricating oil	Gate to gate	Lubricating oil	1997-03-01	A
491	Production of mastic	Gate to gate	Lime Mastic	2000-11-15	A
492	Production of matte copper	Cradle to gate	Matte copper	1998	A
493	Production of Melamin-Urea-Formaldehyde resin 1241(MUF 1241), Wood Adhesive	Cradle to gate	MUF 1241	2003-03-21	A
494	Production of Melamin-Urea-Formaldehyde resin 1242(MUF 1242), Wood Adhesive	Cradle to gate	MUF 1242	2003-03-26	A
495	Production of methanol using energy forest	Gate to gate	Methanol	1996	A
496	Production of methylene diphenyl diisocyanate, MDI (APME)	Cradle to gate	MDI (methylene diphenyl diisocyanate)	1999	S
497	Production of mounting fluid	Gate to gate	SKF LHMF 300	2002-12-12	A
498	Production of nitric acid	Gate to gate	Nitric acid	1999-01-25	A
499	Production of nitric acid (Landskrona)	Gate to gate	Nitric acid	1999-01-25	A
500	Production of nonylphenol and dinonylphenol	Gate to gate	Nonylphenol/Dinonylphenol	1997-03-01	A
501	Production of NP 27-5 fertiliser	Gate to gate	NPK fertiliser	1999-01-25	A
502	Production of NP 27-5 fertiliser AGGR	Cradle to gate	NPK fertiliser	1999	A
503	Production of NPK 20-3-5 fertiliser	Gate to gate	NPK fertiliser	1999-01-25	A
504	Production of NPK 20-3-5 fertiliser AGGR	Cradle to gate	NPK fertiliser	1999	A
505	Production of nylon 66 (APME)	Cradle to gate	PA 66	1999	S
506	Production of orthoxylene. ESA-DBP	Gate to gate	Orthoxylene	1997	A
507	Production of paint and anti corrosion agents	Gate to gate	m3	1996-03-01	A

508	Production of paint, thinner and enamel mainly for surface treatment of steel	Gate to gate	Paint/Enamel/Thinner	1997-03-01	U
509	Production of PE-film	Gate to gate	Film	1991	A
510	Production of pentane (APME)	Cradle to gate	Pentane	1999	S
511	Production of petrochemical Alcohol Ethoxylates (AE) with 3 moles of ethylene oxide (EO)	Cradle to gate	Alcohol ethoxylate (3 EO)	1995-01-01	A
512	Production of petrochemical Alcohol Ethoxylates (AE) with 7 moles of ethylene oxide (EO)	Cradle to gate	Alcohol ethoxylate (7 EO)	1995-01-01	A
513	Production of petrochemical Alcohol Sulphates (AS)	Cradle to gate	1000 kg.	1995-04-01	A
514	Production of phosphoric acid	Gate to gate	Phosphoric acid	1999-01-25	A
515	Production of phosphoric acid (48 % P2O5)	Gate to gate	Phosphoric acid	1999-01-25	A
516	Production of pig iron	Gate to gate	Pig iron	02-12-31	A
517	Production of pig iron - blast furnace process. ESA-DBP	Gate to gate	Pig iron	1996	S
518	Production of plastic strips and film	Gate to gate	ton	1996-03-01	A
519	Production of plywood boxes	Cradle to gate	plywood box	02-12-31	S
520	Production of polyamid 66 containing 30% glass fibre (APME)	Cradle to gate	PA 66 + 30%GF	1999	S
521	Production of polybutadiene (APME)	Cradle to gate	Polybutadiene	1999	S
522	Production of polyethylene resin (HDPE), (APME)	Cradle to gate	HDPE	1999	S
523	Production of polyethylene terephthalate (APME)	Cradle to gate	PET, amorphous	1999	S
524	Production of polymethyl methacrylate (APME)	Cradle to gate	PMMA beads	1999	S
525	Production of polyols (APME)	Cradle to gate	Polyols	1999	S
526	Production of polypropylene (APME)	Cradle to gate	PP	1999	S
527	Production of polystyrene (APME)	Cradle to gate	PS	1999	S
528	Production of polyvinyl chloride, emulsion polymerised (APME)	Cradle to gate	PVC (e)	1999	S
529	Production of polyvinyl chloride, suspension polymerised (APME)	Cradle to gate	PVC (s)	1999	S
530	Production of pork. ESA-DBP	Gate to gate	Pork	2005	S
531	Production of powdered limestone	Cradle to gate	Powdered limestone	1994	U
532	Production of powdered wood	Cradle to gate	Powdered wood	1994	U
533	Production of primary copper	Cradle to gate	Copper	1998	A
534	Production of PVC	Gate to gate	PVC NaOH Hydrochloric acid Dichlore ethane	1996-03-01	U
535	Production of PVC calendered sheet (APME)	Cradle to gate	PVC calendered sheet	1999	S
536	Production of PVC injection moulding (APME)	Cradle to gate	Injection moulded PVC	1999	S
537	Production of PVC pipe (APME)	Cradle to gate	PVC pipe	1999	S
538	Production of PVC unplasticised film APME	Cradle to gate	PVC unplasticised film	1999	S
539	Production of quartz sand	Gate to gate	Sand	02-12-31	A
540	Production of rolled aluminium sheet	Gate to gate	Rolled aluminium sheet	2002-05-07	S
541	Production of self-adhesive labels etc used in the manufacturing, food and pharmaceutical industry	Gate to gate	1996	1997-03-01	U
542	Production of Semichemical Fluting	Gate to gate	Semichemical Fluting	2000-01-18	S
543	Production of SKF Spherical Roller Bearing 232/530	Cradle to gate	Packed bearing	02-12-31	S

544	Production of Soap from palm oil/palm kernel oil	Cradle to gate	Soap	92-04-01	S
545	Production of sodium sulphate	Gate to gate	Sodium sulphate	1991-01-01	U
546	Production of Solvey soda	Gate to gate	Solvay soda	1991-01-01	U
547	Production of styrene (APME)	Cradle to gate	Styrene	1999	S
548	Production of sulphuric acid by roasting of pyrite	Gate to gate	H2SO4	99-01-25	A
549	Production of titanium dioxid	Cradle to gate	Titanium dioxide	1993	U
550	Production of toluene diisocyanate (APME)	Cradle to gate	TDI (toluene diisocyanat	1999	S
551	Production of TSP fertiliser	Gate to gate	Phosphorous fertiliser	1999-01-25	A
552	Production of TSP fertiliser AGGR	Cradle to gate	Phosphorous fertiliser	1999	A
553	Production of turned brass cylinders, 205 kg	Gate to gate	Brass cylinder	2002	A
554	Production of Urea-formaldehyde resin 1202 (UF 1202), Wood Adhesive	Cradle to gate	UF 1202	2000-03-07	A
555	Production of Urea-formaldehyde resin 1205 (UF 1205), Wood Adhesive	Cradle to gate	UF 1205	2000-03-07	A
556	Production of Urea-formaldehyde resin 1206 (UF 1206), Wood Adhesive	Cradle to gate	UF 1206	2000-03-07	A
557	Production of Urea-formaldehyde resin 1274 (UF 1274), Wood Adhesive	Cradle to gate	UF 1274	2000-03-07	A
558	Production of washing soda	Gate to gate	Soda	1991-01-01	U
559	Production of Wetfix I (adhesion promoter used in hot mix for asphalt pavement)	Cradle to gate	Wetfix I	2001-02-13	S
560	Production of Wine Ethanol Fuel (ETAMAX D), excluding grape cultiv. and wine prod.	Cradle to gate	ETAMAX D	1999-01-20	S
561	Production of Wine Ethanol Fuel (ETAMAX D), including grape cultiv. and wine prod.	Cradle to gate	ETAMAX D	1999-01-20	S
562	Production of wood	Gate to gate	Wood	02-12-31	S
563	Production of wood Adhesive PVAC 3316	Cradle to gate	PVAc 3316	2000-02-24	A
564	Production of wood Adhesive PVAC 3318	Cradle to gate	PVAc 3318	2000-02-14	A
565	Production of wood Adhesive PVAC 3326	Cradle to gate	PVAc 3326	2000-02-14	A
566	Propane fired combination plant for heat and power production	Gate to gate	Heat	1999-08-30	S
567	Propane fired plant for heat production - Large plant	Gate to gate	Heat	1999-08-30	S
568	Propane fired plant for heat production - Small plant	Gate to gate	Heat	1999-08-30	S
569	Pulverized wood fired plant for heat and power production - Large plant	Gate to gate	Heat	1999-08-30	S
570	Pulverized wood fired plant for heat production - Small plant	Gate to gate	Heat	1999-08-30	S
571	PVC	Cradle to gate	PVC	1994	A
572	Rail transport - 10 trucks	Unit operation	Cargo	1993-01-01	S
573	Rail transport - 10 trucks	Unit operation	Cargo	1993-01-01	S
574	Rail transport - 52 trucks	Unit operation	Cargo	1993-01-01	S
575	Rail transport - 52 trucks	Unit operation	Cargo	1993-01-01	S
576	Rape seed cultivation. ESA-DBP	Cradle to gate	Rape seed field	2005	A
577	Rapeseed lubricant	Cradle to grave	CH4 Lubricating Oil	2002-12-12	S
578	Rapeseed methyl ester (RME), cradle-to-gate, energy allocation - f3 fuels	Cradle to gate	Rapeseed methyl ester (RME)	2013-11-30	A

579	Rapeseed methyl ester (RME), cradle-to-gate, system expansion, impact categories only - f3 fuels	Cradle to gate	Rapeseed methyl ester (RME)	2013-11-30	A
580	Reconditioning of bearing	Gate to gate	1.2 kg of bearing	2002-12-18	A
581	Recycling and temporary storage of metals	Gate to gate	ton	1995-03-01	U
582	Recycling of polyethene	Gate to gate	Polyethylene	1991	U
583	Red brass sandcasting	Gate to gate	1 kg cast red brass	1995	U
584	Refinery in crude oil based LDPE production process. ESA-DBP	Other	Naphtha	2009	S
585	Refining of crude oil	Gate to gate	Refined oil products	1991	U
586	Refining of crude oil in to diesel	Gate to gate	Diesel	1996	A
587	Refining of crude oil in to petrol	Gate to gate	Petrol	1996	A
588	Reinforcement bar production	Gate to gate	Reinforcement bar	1997-05-01	A
589	Relay assembly	Gate to gate	Relays	2000-03-09	S
590	Remelting of aluminium scrap	Gate to gate	Aluminium ingot	2002-05-07	S
591	Resistor for hole mounting assembly	Gate to gate	Resistor for hole mounting	2000-02-18	S
592	Resistor for surface mounting assembly.	Gate to gate	Resistor for surface mounting	2000-02-24	S
593	Resistor network assembly	Gate to gate	Resistor networks	2000-03-15	S
594	Retapping of cooling medium in tanks	Gate to gate	CFC HCFC HFC	1997-03-01	A
595	Rigid PUR foam	Gate to gate	Rigid	1996	A
596	Ring processes at SKFs site in Göteborg	Gate to gate	Bearing rings	02-12-31	A
597	RME combustion in heavy duty truck or bus, Euro V, tank-to-wheel, f3 fuels	Gate to grave	1 MJ	2013-11-30	A
598	RME combustion in heavy duty truck or bus, Euro VI, tank-to-wheel, f3 fuels	Gate to grave	1 MJ	2013-11-30	A
599	Roll-on-roll-off vessel (RoRo)	Gate to gate	Cargo	1998 08	S
600	RoRo vessel, 2000-30000 dwt	Unit operation	Cargo	1997-11-19	S
601	RoRo vessel, 2000-30000 dwt, future	Unit operation	Cargo	1997-11-19	S
602	Sand extraction and processing. ESA-DBP	Gate to gate	Sand	1996	S
603	Sausage (Hot-Dog) production. ESA-DBP	Gate to gate	Sausage Hot - Dog	2005	S
604	Sausage (Pea-Dog) production. ESA-DBP	Gate to gate	Sausage Pea - Dog	2005	S
605	Sausage (Soy-Dog) production. ESA-DBP	Gate to gate	Sausage Soy - Dog	2005	S
606	Sawed construction timber production	Cradle to gate	Sawed timber	1996-04-02	A
607	Scalable electric traction motor, permanent magnet (PMSM), for EVs	Gate to gate	Electric traction motor, permanent magnet (PMSM), for EVs	2016-07-01	A
608	Scalable inverter unit, electric motor controller, IGBT transistors, for EVs	Gate to gate	Inverter unit, electric motor controller, IGBT transistors, for EVs	2018-10-02	
609	Scrap-based aluminium production	Cradle to gate	Aluminium	1996-05-01	A
610	Scrap-based steel production	Gate to gate	Steel	1996-10-01	A
611	Scrap-based steel production	Gate to gate	Steel	1996-05-01	A
612	Seatbelt assembly. Autoliv ESA-DBP	Unit operation	Seatbelt	2010-07-08	S
613	Seatbelt's bobbin manufacturing. Autoliv ESA-DBP	Gate to gate	Bobbin	2010-07-08	S
614	Seatbelt's car sense ball manufacturing. Autoliv ESA-DBP	Gate to gate	Car sense ball	2010-07-08	S
615	Seatbelt's frame production. Autoliv ESA-DBP	Gate to gate	Metal frame	2010-07-08	S
616	Seatbelt's gas generator assembly. Autoliv ESA-DBP	Unit operation	Gas generator	2010-07-08	S
617	Seatbelt's header manufacturing. Autoliv ESA-DBP	Gate to gate	Header	2010-07-08	S
618	Seatbelt's initiator, serviceable assembly. Autoliv ESA-DBP	Unit operation	Initiator serviceable	2010-07-08	S

619	Seatbelt's label bam manufacturing. Autoliv ESA-DBP	Gate to gate	Label bam	2010-07-08	S
620	Seatbelt's pillar loop production. Autoliv ESA-DBP	Gate to gate	Pillar loop	2010-07-08	S
621	Seatbelt's polyamide granules production. Autoliv ESA-DBP	Unit operation	Polyamide granules	2010-07-08	S
622	Seatbelt's pretensioner retractor assembly. Autoliv ESA-DBP	Unit operation	Pretensioner retractor	2010-07-08	S
623	Seatbelt's rivet nut manufacturing. Autoliv ESA-DBP	Gate to gate	Rivet nut	2010-07-08	S
624	Seatbelt's short tube assembly. Autoliv ESA-DBP	Unit operation	Short tube	2010-07-08	S
625	Seatbelt's solder paste manufacturing. Autoliv ESA-DBP	Gate to gate	Solder paste 1	2010-07-08	S
626	Seatbelt's spindle assembly. Autoliv ESA-DBP	Unit operation	Spindle	2010-07-08	S
627	Seatbelt's spring antiretour manufacturing. Autoliv ESA-DBP	Gate to gate	Spring antiretour	2010-07-08	S
628	Seatbelt's spring, wire manufacturing. Autoliv ESA-DBP	Gate to gate	Spring, wire	2010-07-08	S
629	Seatbelt's synchronization ball manufacturing. Autoliv ESA-DBP	Gate to gate	Synchronization ball	2010-07-08	S
630	Seatbelt's tongue production. Autoliv ESA-DBP	Gate to gate	Tongue	2010-07-08	S
631	Seatbelt's tube manufacturing. Autoliv ESA-DBP	Gate to gate	Tube	2010-07-08	S
632	Seatbelt's web sensor manufacturing. Autoliv ESA-DBP	Gate to gate	Web sensor	2010-07-08	S
633	Seatbelt's webbing manufacturing. Autoliv ESA-DBP	Gate to gate	Webbing	2010-07-08	S
634	Si wafer production and Si wafer processing for integrated circuits	Gate to gate	Silicon wafer	2000-03-03	S
635	Si wafer production and Si wafer processing for transistors	Gate to gate	Silicon wafer	2000-03-07	S
636	Silviculture of softwood AGGR	Cradle to gate	Forest land Softwood at roadside	1999	A
637	Sinter plant's process ESA-DBP	Gate to gate	Sinter	1996	S
638	Slow speed, two-stroke diesel vessel engine	Unit operation	Mechanical work	1991-01-01	A
639	Slow speed, two-stroke diesel vessel engine	Unit operation	Mechanical work	1991-01-01	A
640	Smelt iron in a ladle	Unit operation	Iron	02-12-31	S
641	Smelt iron in a teaming ladle before casting	Unit operation	Iron	02-12-31	A
642	Smelting of iron, type V10	Unit operation	Iron	02-12-31	S
643	Soil preparation	Gate to gate	Cultivated forest area	1994-02-24	A
644	Solid waste management AGGR	Gate to grave	Compost Electricity	2002	S
645	Solid wood flooring. ESA-DBP	Cradle to grave	Solid wood flooring	1994	S
646	Sorting of solid municipal waste	Gate to gate	Biowaste Waste to incineration Waste to landfill Waste to recycling	2002-08-14	S
647	Soy bean cultivation. ESA-DBP	Cradle to gate	Soy bean field	2005	S
648	Soy bean processing. ESA-DBP	Gate to gate	Processed soy bean	2005	S
649	Spain, electricity generation mix 1998	Unit operation	Electricity	2001-01-31	A
650	Stage performance in a theatre. ESA-DBP	Gate to gate	Performance for 1 person	2010	S
651	Stage performance in an opera. ESA-DBP	Gate to gate	Performance for 1 person	2010	S

SPINE LCI dataset: ''Other'' electronic components assembly

Administrative	
Finished	Y
Date Completed	2000-03-15
Copyright	Ericsson
Availability	Official

Technical System	
Name	''Other'' electronic components assembly
Functional Unit	One gram of ''odd'' (other) electronic component
Functional Unit Explanation	The motivation for choosing this functional unit is: · Suitable unit to work with in an LCA of a private branch exchanges (a complicated telecom product) · Important component of the MD110 product system and many other electronic products. DESIGN These facts are based on Ericsson technical specification of the components. -- Component manufacturer one -- Ericsson product number: RMD 994 002/1 Ericsson description: Push-button switch. General: The push button switch is intended for keyboards and similar applications, where it is mounted on a circuit board. The switch is available in a non-locking model only. PCB thickness 1.6 mm. Design general: Material Lower housing: PA 6.6 GV (Nylon) Upper housing: PA 6.6 GV (Nylon) Contact spring: Phosphorous bronze Actuated stem: Acetal plastic Surface treatment: Contact area: 0,25e-6 m AuAg on Ni Soldering terminals: SnPb on Ni Dimensions Height: 18.5 mm, Length: 15,6 mm, Width: 15,6 mm, Terminal thickness: 2,54 mm Weight: 1,584 g (Ericsson: 2 g) -- Component manufacturer two -- Ericsson product number: RLE 113 500/1 Ericsson description: Loudspeaker. General: Loudspeaker intended for panel mounting, with plastic frame. Diameter 50 mm. Design general: Weight app. 47 g (Ericsson specification) Material Frame: Polystyrene (PS) Membrane: Polycarbonate (PC) Surface treatment: Soldering tags shall be pre-tinned Dimensions: Height: 50 mm (diameter) Length: 22.6 mm Width: 50 mm (diameter) Terminal thickness: 0.5 mm Weight: 6.8 g (acc. to CM2)
Process Type	Gate to gate

Site	Not relevant
Sector	Manufacturing
Owner	Not relevant
Technical system description	This activity includes the final assembly of an ''other'' electronic component. The activity is an average based on information acquired from two manufacturers. The model for the component is based on systems for a toggle-switch and a loudspeaker. The description of the process is supplied by both manufacturers and is assumed to be general for manufacturing of ''other'' electronics. The following process steps are included; --Component manufacturer one-- Component manufacturer one assembles loudspeakers. The following steps are included: 1. Voice coil winding 3. System moulding 2. Voice coil moulding 4. Inserting tags 5. Voice coil mounting 6. Welding 7. Glue application 8. Membrane deepdrawing 9. Inserting of membrane 10. Hardening of glue 11. Insert dustcap 12. Hardening of glue 13. Magenitzation 14. Acoustic test 15. Packing Detalis given about some steps: 1.Voice coil winding: Mechanized winding and baking of self-supporting coil 2. Voice coil moulding: The coil is covered with plastics together with the lead wires, then connection of lead wires to coil wire by spark welding. 3. System moulding: The magnet system is moulded in plastic together with forming the basket in one step 8. Membrane deepdrawing: The plastic membrane is manufactured at the line by a special thermoforming machine 6. Welding: The tags are connected to the lead wires by resistance welding 7. Glue application: Usage of UVA- hardening glues 14. Acoustic test: 100% manual testing --Component manufacturer two-- Component manufacturer two assembles toggle-switches. The following steps are included: 1. Supply of punching material 2. Punching of terminals 3. Parts supply at automates 4. Automated assy. incl. testing 5. Packaging 6. Final testing 7. Shipment Details given: - terminals are punched and the gold file is welded onto the parts within the same process - assembly and testing is done on round assembly automate; no further work procedures are required

System Boundaries

Nature Boundary	The emissions to air and ground have nature as recipient. Each parameter mentioned by the component manufacturers has been studied. No parameter has deliberately been disregarded when environmental impact has been studied. Included component manufacturers have not specified the same parameters. In the cases where only one manufacturer has stated a parameter this has been used. Emissions to water are not included due to lack of data.

Time Boundary	1998 The answer from the manufacturer arrived in 1998 and they measured in 1998. The process technology used is most certainly the best available as the factories are located in western Germany and Austria and the companies are well established.
Geographical Boundary	The technical system for this model is limited to the factory where the production takes place. The manufacturers included in the average are located in Germany and Austria.
Other Boundaries	Delimitation's to the system is the final step in the making of the ''odd'' electronic component. The model for the component is based on systems for a toggle-switch and a loudspeaker. The production of the subparts (e.g. for the switch socket, cover, actuator and springs) of the switch is not included in this model. The transportation of them to the factory is not included. For interested parties who wish to include the transport figures given from the manufacturers, can find the figures in the section Applicability.
Allocations	The manufacturers have not described how the allocation has been made. We did not decide or have any suggestions on how the manufacturer should allocate in their factory.
Systems Expansions	None.

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, unspecified
Represents	
Method	The calculation for all flows is done like this: First the amount of each flow per functional unit is calculated then each unique flow is summed and divided by the number of answers. This gives the average values for each flow. Definition of variables: CMn: Component manufacturer number n. Myn: Materials, emission, waste, energy (y) given in component answer n. ACyn: Amount of material y in component, expressed in mg (or similar) by component manufacturer n Wn: Weight of one piece of component, expressed in mg (or similar) by component manufacturer n. Nyn: The flow y expressed per functional unit from manufacturer n. Step 1. For CM1 sum AC1+..+.ACn Step 2: The sum AC11+..+.ACyn = W1 Step 3: Divide all flows between M11...M1n by W1 --> N11...N1n Step 4: Repeat Step 1 to 3 for all component manufacturers and for each flow. Step 5: Sum N1n+..Nyn and divide by the number of terms for each unique flow.(material input, emission etc.) An average calculation like above of up to three answers was made.
Literature Reference	Two answers from one loudspeaker manufacturer and one push-button switch manufacturer manufacturers make up this LCI model.
Notes	None

Flow Table and Specific Meta Data

QMetaData	***Direction***	***FlowType***	***Substance***	***Quantity***	***Min***	***Max***	***Unit***	***Environment***	***Geography***
Date concieved: 1998 Data type: Derived, unspecified Method: CM1: (340 mg + 228 mg) / 1584 mg = 0.358 g/g (In contact bracket and moving blade respectively) CM2: 300 mg/6854,8 mg = 0.044 g/g (CM1+CM2)/2 = 0.201 g brass/g other electronic component This is an average value based on two answers.	Input	Refined resource	Brass	0.201			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM2: 3.5 mg/6854.8 mg = 0.00051 g/g (Packaging material used by CM2) This is not an average value and the figure is based only on one answer.	Input	Refined resource	Cardboard	0.00051			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM2: 0.75 mg/6854.8 mg = 0.0001094 g/g This is not an average value and the figure is based only on one answer.	Input	Refined resource	Cd	0.0001094			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM2: 170 mg/6854.8 mg = 0.024 g/g (In ceramic magnet) This is not an average value and the figure is based only on one answer.	Input	Refined resource	Ceramic	0.024			g	Technosphere	

Date concieved: 1998 Data type: Derived, unspecified Method: CM2: 155mg /6854.8 mg = 0.023 g/g This is not an average value and the figure is based only on one answer.	Input	Refined resource	Copper	0.023			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM1: 1 mg/ 1584 mg = 0.00063 g/g (In wire as Ni, AuAg alloyed) This is not an average value and the figure is based only on one answer.	Input	Refined resource	Cu alloy	0.00063			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Loudspeaker manufacturer, CM2, states a use of 10 mg ink for one loudspeaker (''other'' component) which weighs 6,8548 grams. Hence, 10e-3/6,8548 = 1,46e-3 g /g other This is not an average value and the figure is based only on one answer.	Input	Refined resource	Dyes	0.00146			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Loudspeaker manufacturer, CM2, states an electricty consumption of 71 Wh for one loudspeaker (''other'' component) which weighs 6,8548 grams. Hence, 71/6,8548 = 10,357 Wh /g other Switch manufacturer, CM1, states an electricty consumption of 15,2 kJ for one switch (''other'' component) which weighs 1,584 grams. 1 Wh = 3,6 kJ Hence, 15,2/(3,6*1,584) = 2,665 Wh /g other Average value: (10,357 Wh /g other + 2,665 Wh /g other)/2 = 6,51 Wh/g This is an average value and the figure is based on two answers.	Input	Refined resource	Electricity	6.51			Wh	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM2: 100 mg/6854.8 mg = 0.0146 g/g (UV-Glue) This is not an average value and the figure is based only on one answer.	Input	Refined resource	Glue	0.0146			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Switch manufacturer, CM1, states a use of hydrogen of 0,00002 mg for one switch (''other'' component) which weighs 1,585 grams. Hence, 0,00002e-3/1,585 = 1,26e-8 g/g other This is not an average value and the figure is based only on one answer.	Input	Refined resource	Hydrogen	1.26E-08			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM1: 0.0032 mg/ 1584 mg = 2.02e-6 g/g (Oil, punching) This is not an average value and the figure is based only on one answer.	Input	Refined resource	Oil	2.02E-06			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Switch manufacturer, CM1, states a use of solvent of 0,0004 mg for one switch (''other'' component) which weighs 1,585 grams. Hence, 0,0004e-3/1,585 = 2,52e-7 g/g other This is not an average value and the figure is based only on one answer.	Input	Refined resource	Oxygen	2.52E-07			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM2: 1200 mg/6854.8 mg = 0.175 g/g This is not an average value and the figure is based only on one answer.	Input	Refined resource	PC	0.175			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM2: 15 mg/6854.8 mg = 0.00218 g/g This is not an average value and the figure is based only on one answer.	Input	Refined resource	Poly(butylene terephthalate)	0.00218			g	Technosphere	

	Date concieved: 1998 Data type: Derived, unspecified Method: CM1: 260 mg / 1584 mg = 0.164 g/g (In actuator) This is not an average value and the figure is based only on one answer.	Input	Refined resource	Polyacetal	0.164			g	Technosphere	
	Date concieved: 1998 Data type: Derived, unspecified Method: CM1: (687 mg + 374 mg) / 1584 mg = 0.669 g/g (In socket and cover respectively) CM2: 170 mg/6854,8 mg = 0.024 g/g (CM1+CM2)/2 = 0.347 g PA/g other electronic component This is an average value based on two answers.	Input	Refined resource	Polyamides	0.347			g	Technosphere	
	Date concieved: 1998 Data type: Derived, unspecified Method: CM2: 6500 mg/6854.8 mg = 0.948 g/g This is not an average value and the figure is based only on one answer.	Input	Refined resource	Polystyrene	0.948			g	Technosphere	
	Date concieved: 1998 Data type: Derived, unspecified Method: CM2: 1 mg/6854.8 mg = 0.000146 g/g This is not an average value and the figure is based only on one answer.	Input	Refined resource	Sn/Pb plating	0.000146			g	Technosphere	
	Date concieved: 1998 Data type: Derived, unspecified Method: Switch manufacturer, CM1, states a use of solvent of 0,04 mg for one switch (''other'' component) which weighs 1,585 grams. Hence, 0,04e-3/1,585 = 2,52e-5 g/g other This is not an average value and the figure is based only on one answer.	Input	Refined resource	Solvent	0.0000252			g	Technosphere	
	Date concieved: 1998 Data type: Derived, unspecified Method: CM1: 64 mg / 1584 mg = 0.04 g/g (In spring as CrNi steel) CM2: 220 mg/6854,8 mg = 0.032 g/g (CM1+CM2)/2 = 0.036 g stainless steel/g other electronic component This is an average value based on two answers.	Input	Refined resource	Stainless steel	0.036			g	Technosphere	
	Date concieved: 1998 Data type: Derived, unspecified Method: Loudspeaker manufacturer, CM2, states an emission to soil of 3 mg brass for one loudspeaker (''other'' component) which weighs 6,8548 grams. Hence, 3e-3/6,8548 = 4,38e-4 g brass/g other This is not an average value and the figure is based only on one answer. Literature: Answer from one manufacturer	Output	Emission	Brass	0.000438			g	Ground	
	Date concieved: 1998 Data type: Derived, unspecified Method: Loudspeaker manufacturer, CM2, states an emission to soil of 0,003 mg cadmium for one loudspeaker (''other'' component) which weighs 6,8548 grams. Hence, 3e-6/6,8548 = 4,38e-7 g /g other This is not an average value and the figure is based only on one answer.	Output	Emission	Cd	4.38E-07			g	Ground	
	Date concieved: 1998 Data type: Derived, unspecified Method: Loudspeaker manufacturer, CM2, states an emission to soil of 1,7 mg ceramic magnet for one loudspeaker (''other'' component) which weighs 6,8548 grams. Hence, 1,7e-3/6,8548 = 2,48e-4 g/g other This is not an average value and the figure is based only on one answer.	Output	Emission	Ceramic	0.00025			g	Ground	
	Date concieved: 1998 Data type: Derived, unspecified Method: Switch manufacturer, CM1, states an emission to air of 0,003 mg for one switch (''other'' component)	Output	Emission	CO	1.89E-06			g	Air	

which weighs 1,585 grams. Hence, 3e-6/1,585 = 1,89e-6 g/g other This is not an average value and the figure is based only on one answer.									
Date concieved: 1998 Data type: Derived, unspecified Method: Loudspeaker manufacturer, CM2, states an emission to soil of 1,45 mg copper for one loudspeaker (’’other’’ component) which weighs 6,8548 grams. Hence, 1,45e-3/6,8548 = 2,12e-4 g brass/g other This is not an average value and the figure is based only on one answer.	Output	Emission	Cu	0.000212			g	Ground	
Date concieved: 1998 Data type: Derived, unspecified Method: Loudspeaker manufacturer, CM2, states an emission to soil of 1,00 mg acrylatic glue for one loudspeaker (’’other’’ component) which weighs 6,8548 grams. About Inventory

Publication	Not available -- Data documented by: Anders Andrae, Ericsson Business Networks AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The intended use for this LCI
General Purpose	The general purpose with this LCI model was for application in a LCA project at Ericsson Business Networks. The main goal of the study is; to compare the potential environmental impacts associated with an old (BC 8) and a new model (BC 10) of a private branch exchange (PBX) system, namely the MD110 system, and an additional objective is to include comparisons between different stages of the life cycle (e.g. manufacturing, use and end of life) of the system. The system, PBX MD110, is designed, developed and delivered by Ericsson Enterprise Systems AB. Life-Cycle Assessment methodology (following the ISO14040 standards for LCAs) will be used to determine the environmental impacts. The main purpose of the study for Ericsson is; - to learn, test and evaluate the LCA-methodology as a tool for assessing environmental improvement options in the product design process, and to make up concrete product guidelines regarding design for environment (DfE) and - to evaluate environmental aspects in new design. The relative importance for different life cycle stages may also be an important input in the internal work with an Environmental Management System for Ericsson Enterprise Systems. Another purpose of the study is; to collect and qualify data from suppliers and literature in order to build up a database for this and future LCA activities and within the project, it is also intended to analyse the possibilities to use the study as a base for future work regarding a type III ecolabeling project within Ericsson. The intended audience of the report from the project is; Ericsson's personnel: project management, system management, design, marketing and sales organisation, and thus also (in an extracted version) the Ericsson customers.
Detailed Purpose	Map an ''other'' electronic component process from an environmental standpoint in a structured procedure. The purpose of the project was to collect resource consumption data and emission data connected with the final assembly of ''other'' electronics and resembling components in our telecom products. Examples of odd electronic components are microphones, loudspeakers, batteries, antennas, switches, floopy disks, footpedals, headsets, fuses and circuit breakers. The usage for this set of data is life cycle assessments where ''odd'' electronics are part of the studied system. Note: This model is one of in total eighteen models compiled at Ericsson, describing 16 component groups in the PBX. The division into component groups is based on structural resemblance, electrical function and material contents of the different components. -- Below is a list of the component groups and corresponding models that have been compiled: 1. Cables - Model: Cable assembly 2. Capacitors and filters; hole mounted devices - Model: Capacitor for hole mounting assembly 3. Capacitors; surface mounted devices - Model: Capacitor for surface mounting assembly 4. Connectors and holders - Model: Connector assembly 5. Diodes - Model: Diode wafer production and assembly

	6. Display units and indicators - Model: Liquid crystal display assembly 7. Microcircuits, oscillators, quartz crystal units and delay lines (2 models) - Models: 1. Integrated circuit capsule assembly and 2. Si wafer production and Si wafer processing for integrated circuits (these models are interlinked) 8. Other - Model: ''Other'' electronic component assembly 9. Potentiometers - Model: Potentiometer assembly 10. Printed boards - Model: Printed board assembly 11. Relays - Model: Relay assembly 12. Resistor networks - Model: Resistor network assembly 13. Resistors, varistors and thermistors; hole mounted devices - Model: Resistor for hole mounting assembly 14. Resistors; surface mounted devices - Model: Resistor for surface mounting assembly 15. Transformers and inductors - Model: Inductor assembly 16. Transistors and opto couplers (2 models) - Models: 1. Transistor assembly and 2. Si wafer production and Si wafer processing for transistors (these models are interlinked)

Applicability	This set of data can be applied to ''other'' electronic components in electronic equipment if you know how much the components weigh. See Functional Unit Explanation for a description of what is included in ''other'' electronic component. Generally, ''Other'' components are components that can not be fitted into these groups: 1. Display units and indicators 2. Diodes 3. Microcircuits, oscillators, quartz crystal units and delay lines (2 models) 4. Transistors and opto couplers (2 models) 5. Connectors and holders 6. Cables 7. Relays 8. Transformers and inductors 9. Potentiometers 10. Resistors, varistors and thermistors; hole mounted devices 11. Resistors; surface mounted devices 12. Resistor networks 13. Capacitors and filters; hole mounted devices 14. Capacitors; surface mounted devices 15. Printed boards Examples of other electronic components are microphones, loudspeakers, batteries, antennas, switches, floopy disks, footpedals, headsets, fuses and circuit breakers. -- Transports. -- Here follows a more detailed description of transports of materials and components to the respective manufacturer factories. These transports are not included in the model. CM1 = Component manufacturer one The calculation for all modes of transport is done like this: First the total transportation work per functional unit is calculated for each included component manufacturer. Then the total transportation is summed and divided by the number of included component manufacturers. This gives the average value for transportation by each mode of transport. -- Truck transportation: -- Component manufacturer one (CM1): Weight of component: 1.584 g Socket with weight 0.687g is transported 90 km by truck, i.e. 0.687 g * 90 km Cover 0.374*110, Actuator 0.260*110 and Spring 0.064*280 The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives: 149,49 gkm /1,584 g = 94,375 gkm /g other

	Component manufacturer two (CM2): Weight of component: 6.8548 g Steel 0.22 g * 1200 km Ceramic (Magnet) 0.17*1200 km Polystyrene 7*800, Polyamide 0.17*20, PC-film 1.2*1000 Brass (tag) 0.3*1100 UV-Glue 0.1*500 Cardboard (packing) 0.0035*15 Ink 0.01*20 Coil wire 0.15*200 Lead wire 0.005*20 This gives: 7680.3525 gkm /6,8548 g = 1120.43 gkm /g other This gives the average total transportation work by truck for CM1 and CM2: (CM1+CM2)/2 = 607.41 gkm/g -- Airplane transportation: -- Component manufacturer two (CM2): Weight of component: 6.8548 g Mylar (cap) 0.015*10000 km Mylar is a polyester plastic material. This gives: 150 gkm/6.8548 g = 21.88 gkm/g other -- Boat transportation: -- Component manufacturer two (CM2): Weight of component: 6.8548 g Steel 0.22 g * 10000 km Ceramic (Magnet) 0.17*10000 km This gives: 3900 gkm/6.8548 g = 568.94 gkm/g other
About Data	The data is based on information from one German and one Austrian manufacturer. The information was gathered using a life cycle inventory questionnaire. All flows are not average values and where there were only one manufacturer stating a certain flow, this one was chosen in the model. Of the flows about little more than 90 % are not average values. The flows for Energy input of Electricity, Raw material input of Brass, PA and Stainless Steel are average values. In specific QMetaData for each flow, we have indicated specifically for each flow how many manufacturers have been included. The figures in the original answer from the manufacturers should all have a special tag telling if the value has been calculated, measured or estimated or a combination of two or three of them. Ericsson specifically told the manufacturers to do so. The result is that approximately 57 % of the flows used in all manufacturers answers were only calculated, 7 % were only estimated, 36 % were only measured. The outline of the LCI data questionnaire that was used in the inventory follows below. No limitations or specifications were set for which substances they had to account -- LCI data questionnaire -- Transport description: Material type, Used weight of Material (g)/functional unit, Transport by road of Material (km), Transport by boat of Material (km), Transport by rail of Material (km). We here only asked for flows exceeded 2% by weight of the material declaration of the component. Additional information was also asked for and here some manufacturers mentioned they had aeroplane transport instead of some of the other transport modes. Process description.

	Description of the entire production at the plant/site and a technical description of the plant production. Description of the production line of the studied product. Flow chart of process steps for production of the studied product. Technical description of the production line. A very short description of each unit operation. Data quality. For every figure you give, give an account on how you gathered it. C = calculated, E = estimated, M = measured. General LCA-related information on the production system (Allocation procedures, system boundaries, etc.). Additional information. (E.g. planned changes in production rate) Material, components and natural resource input, etc. We told them to express data in amount per functional unit. Name of material, component or resource. Used amount (mg). Amount In Product (mg). Additional information Energy-ware input Energy -ware source. Quantity/functional unit. Unit. Energy-ware supplier, production sites (address). Suppliers of transport (address). Additional information. Emissions. Emissions to air. Indicate whether emissions from energy use are included in the data. Name of emission to air. Emission to air/functional unit (mg). Additional information. Emissions to water. Indicate if data describes emissions going to external purification plant or directly to recipient. Name of emission to water. Emission to water/functional unit (mg). Additional information. Emissions to soil. Name of emission to soil. Emission to soil/functional unit (mg). Additional information. Waste. Name of waste. Waste/functional unit (mg). Recycled/functional unit (mg). Additional information.

SPINE LCI dataset: Air-and-water air conditioning system. ESA-DBP

Administrative	
Finished	Y
Date Completed	2007
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Air-and-water air conditioning system. ESA-DBP
Functional Unit	Treatment and the distribution of totally 34 m3/s airflow for 17000 m2 landscape office area, when the cooling loads are totally 1189 MWh/year.
Functional Unit Explanation	For the whole building, four air-handling units of similar size are designed for the offices, and two smaller air handling units for the technical equipment and services. The data are valid for 1 year.
Process Type	Cradle to gate
Site	Unknown
Sector	Goods and services for households
Owner	Unknown

Technical system description	Schematics of the system can be found in the reference report (see 'Publication'). Excerpt from the report, see 'Publication': ''In the late 1980s, usage of air-and-water systems became as common as that of all-air systems. These systems may demand more materials owing to the distribution systems for two cooling agents: air and water. (...) Besides the air handling unit and chiller, the distribution systems for air, i.e. air ducts etc., and water, i.e. pipes and supply air beams etc., are also included. (...) The six storeyed building, with an office area of 17000m2, is situated in the south-west of Sweden, in Gothenburg. Besides offices, the building contains also conference area, canteen and the place for the technical equipment. For the LCA study, however all storeys are assumed to be similar. A storey (ca 2850 m2) consists of an office landscape area that is divided into work places (each of 12 m2). The internal loads during the workday (8.00-17.00) are estimated to 37 W/m2, comprising 15 W/m2 for lighting, 13 W/m2 for computerised equipment, and 9 W/m2 for occupants. The air temperature in offices during the summer varies between 23.5-25-5 °C. (...) The function of the AC system is to assure that the requirements for the thermal comfort in offices will be achieved. (...) For the whole building, four air-handling units of similar size are designed for the offices, and two smaller air-handling units for the technical equipment and services. (...) To achieve the predicted thermal climate in offices, the AC system is supplying an airflow of 2.3 l/s.m2 at 17° C. The airflow is distributed partly by SATD, and party by SAB, which are additionally cooled by water at 7°C.'' Main assumptions made for this study are (NB: based on the comparative table): air-and-water; vapour compression technique of cooling; constant airflow, reduced during the night; air-conditioning system; life cycle phases: production, user; office area: 17000 m2; total airflow: 34m3/s; supply air temperature: 17°C, exhaust air temperature 25°C; internal heat loads 37 W/m3; cooling loads: 1189 MWh/year; operating time: 8760 h/year, SFP: 2.5 kW/(m3/s), life span: 15 years. This process is included in the system described in: Heikkilä K. (2007). Environmental Assessment of Air-conditioning Systems. Design Considerations for Swedish Conditions. Report no. D 2007:2, Department of Building Services Engineering, Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/Heikkila_et_al_2007 Other processes in the CPM Database also included in the above publication: - Bore-hole based air-conditioning system. ESA-DBP - Air-conditioning system. ESA-DBP - All-air air handling unit with a cooling coil and vapour compression chiller with a refrigerant. ESA-DBP - All-air desiccant cooling air handling unit. ESA-DBP - Operation on desiccant cooling system - a technology in air conditioning. ESA-DBP - Operation on vapour compression cooling system - a technology in air conditioning. ESA-DBP

System Boundaries

Nature Boundary	In the study production of the materials and the use phase are considered. The inventory analysis included parameters describing resource use and emissions to air and water.
Time Boundary	2001
Geographical Boundary	Göteborg, Sweden
Other Boundaries	Main assumptions made for this study are (NB: based on the comparative table): air-and-water; vapour compression technique of cooling; constant airflow, reduced during the night; air-conditioning system; life cycle phases: production, user; office area: 17000 m2; total airflow: 34m3/s; supply air temperature: 17°C, exhaust air temperature 25°C; internal heat loads 37 W/m3; cooling loads: 1189 MWh/year; operating time: 8760 h/year, SFP: 2.5 kW/(m3/s), life span: 15 years. Excerpt from the report, see 'Publication': ''Air handling units for technical equipment are excluded from the calculations. (...) In this study, net amounts of raw material in each specific component of the AC system system are included. Manufacturing processes of components, as well as wastes related to these processes, are excluded from the study. Moreover, all transports of materials and components between the different places of their production and assembly of the AC system are assumed to be comparable apart from its type, and therefore excluded from the study. Minor materials, whose weight is represented by less than 1% of the total weight of a component, are excluded from calculations as their impact is neglected campared to the whole AC system and its use. Furthermore, the ducts of the cooling medium and the pumps in the vapour compressor chiller, as well as the brine ducts connecting the vapour compressor chiller with the cooling coil in the air handling unit (...) are not included. Impacts of air dampers and silencers in the air distribution system are assumed to be comparable with impact of air ducts. Various types of valves in the water distribution system are assumed to have the same environmental performance as the ducts. Material amounts of branch ducts of both distribution systems, air and water, are neglected as they are small compared to the material amounts of the whole AC system. Environmental impacts of the refrigerant of the vapour compressor chiller are calculated only as emission due to missing inventory data for the manufacturing processes. The disposal phase of the life cycle of the system is not inlcuded in the study, because of the

	uncertainty of a possible waste scenario that can not be affected by designers at the design stage.''

Intended User	LCA practitioner
General Purpose	Excerpt from the report, see 'Publication': ''An objective of this work was that it should lead to an increased knowledge of how to work with environmental issues related to air-conditioning systems for office buildings and to a greater awareness of the environmental loads related to these systems. (...) The objectives of this thesis are to: - describe how the environmental performance of air-conditioning systems can be assessed and evaluated at the design stage. The focus is on the application of existing methods for

	environmental assessment of these systems. - identify and discuss the major sources of the environmental impacts and give some general recommendations as to how to design air-conditioning systems to improve their environmental performance. - outline possible key performance indicators (KPI) for the environmental performance of the most common types of air-conditioning systems.''
Detailed Purpose	Excerpt from the report, see 'Publication': ''The primary task in this case study is to account for the environmental performance of the designed system to the customer. (...) The results are intended for an internal usage in the company designing the AC system.''

About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	For more information and the comparison with the other systems see the report. The reference report is a thesis for the degree of doctor. As a part of it, seven papers are included. Paper III ''Evaluation of environmental impacts of air-conditioning systems at the design stage'' relates to the analysis of air-and-water system. The function and other information was taken from the mentioned Paper III. Inventory data come from the main part of the report.

SPINE LCI dataset: Airbag's can production. Autoliv ESA-DBP

Administrative	
Finished	Y
Date Completed	2010-07-08
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Airbag's can production. Autoliv ESA-DBP
Functional Unit	1 unit of can
Functional Unit Explanation	1 can weighs 240 grams while the whole airbag weighs 1.56 kg
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	The can is a part of the airbag produced by Autoliv which is a construction frame for the rest of the parts: cushion, inflator and the cover. A frame is common for different constructions where the solid frame or base are needed. Similar part with comparable function can be found in a seatbelt and it is called 'frame'. The can is produced in Sweden. It is made of zinc galvanized steel and is assembled with snap in pinne. It weighs 240 grams.

	The manufacturing process consists of the following steps: 1. Slitting the steel sheet 2. Punching on stamping press machine 3. Zinc galvanization 4. Assembling with the base can This process is included in the system described in: Mujiyanto A., Priyojati S. (2010). Life cycle assessment of Autoliv's Driver Airbag. Master thesis report. ESA report 2010:1, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. System Boundaries

Nature Boundary	The performed study is gate-to-gate. It starts with processing the materials from the suppliers and ends with assembling the final product. Data given by can manufacturer do not show any emissions. Steel scrap is produced.
Time Boundary	The data were acquired in 2009.
Geographical Boundary	The manufacturer is located in Sweden.
Other Boundaries	Excerpt from the report, see 'Literature reference': ''The production infrastructure, maintenance and capital goods as well as personnel related environmental impact are excluded in this study.''
Allocations	The allocation procedure was applicable in case of electricity and water consumption. Those values were given for the annual production. Allocation was based on the value on annual production and value of studied product.
Systems Expansions	Not applicable

	/ESA_2010--1.pdf>http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2010--1.pdf
Intended User	LCA practitioner
General Purpose	Autoliv has decided to perform 4 LCA projects for the following products: airbag, seatbelt, night vision camera (NVC) and electronic control unit (ECU). The main purpose was to learn more about the products and their environmental performances and eventually decrease their impact on the environment.
Detailed Purpose	The discussed can is a part of the airbag which was the object of the study. The main goals of the study are: (excerpt from the report, see 'Literature reference') ''1. To identify the environmental impacts that can be associated with the airbag. 2. To analyze several environmental impacts such as consumption of different resources, e.g. energy, water, materials, etc., emissions of specific pollutants such as CO2, NOx, SO2, etc. and amount of generated wastes. 3. To determine the relative environmental load of the airbag package compared to a complete car. 4. To determine whether there are materials in the product that should be avoided for environmental reasons.''

Reviewer	Birgit Brunklaus & Henrikke Baumann -
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Year 2010. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: the Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environemental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	In the study it was assumed that the scenario for the end of life is that the airbag is shredded together with the car. Before that it has to be deployed in the specialized garage. The assumption made in the project says that 80% of the airbag will be recycled. The rest consists mainly of resins, rubber, glass, textile etc. The studied product is a part of the airbag which was the object of the LCA study for Autoliv. More processes from the same study were also documented in this database. In parallel to the airbag, 3 other LCA studies for Autoliv were carried out (for seatbelt, night vision camera and electronic control unit). Some of the processes can be found also in the CPM database.

SPINE LCI dataset: Airbag's cushion manufacturing. Autoliv ESA-DBP

Administrative	
Finished	Y
Date Completed	2010-07-08
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Airbag's cushion manufacturing. Autoliv ESA-DBP
Functional Unit	1 unit of cushion
Functional Unit Explanation	1 cushion weighs 290 grams while the whole airbag module 1560 grams
Process Type	Gate to gate
Site	Unknown

Sector	Manufacturing
Owner	Unknown
Technical system description	The studied cushion is a part of a driver's airbag which is filled with the gas after the crash. It is the white 'bag' which is inflated and protects the occupant against hitting the steering wheel or other parts in the car. The cushion is manufactured in Portugal. It consists of 4 main parts: polyamide 6.6 fabric and thread, reinforcing glass fibre, and a label. The cushion weighs 290 grams. The production process consists of the following steps: 1. Spreading and cutting the fabrics 2. Marking the fabric with folding and cutting pattern 3. Sewing the pieces 4. Laser cutting 5. Enveloping the seams 6. Folding and labeling 7. Metal detection and packing This process is included in the system described in: Mujiyanto A., Priyojati S. (2010). Life cycle assessment of Autoliv's Driver Airbag. Master thesis report. ESA report 2010:1, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2010--1.pdf Other processes in the CPM Database also included in the above publication: - Airbag's can production. Autoliv ESA-DBP - Airbag's igniter granules manufacturing. Autoliv ESA-DBP - Airbag's inflator assembly. Autoliv ESA-DBP - Airbag's initiator assembly. Autoliv ESA-DBP - Airbag's label manufacturing. Autoliv ESA-DBP - Airbag's nut manufacturing. Autoliv ESA-DBP - Airbag's shunt ring manufacturing. Autoliv ESA-DBP

System Boundaries

Nature Boundary	The performed study is gate-to-gate. It starts with spreading and cutting the fabrics and ends with metal detection and packing. Data given by cushion manufacturer do not show any emissions. The fabric and thread waste is produced.
Time Boundary	The data were acquired in 2009. Data for electricity and water consumption come from July-September 2009.
Geographical Boundary	The manufacturing plant is located in Portugal.
Other Boundaries	Excerpt from the report, see 'Literature reference': ''The production infrastructure, maintenance and capital goods as well as personnel related environmental impact are excluded from this study.''
Allocations	The allocation procedure was applicable in case of electricity and water. Those values were given for the monthly production. Allocation was based on the value on monthly production and value of studied product.
Systems Expansions	Not applicable

SPINE LCI dataset: Airbag's igniter granules manufacturing. Autoliv ESA-DBP

Administrative	
Finished	Y
Date Completed	2010-07-08
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Airbag's igniter granules manufacturing. Autoliv ESA-DBP
Functional Unit	1kg of igniter granules
Functional Unit Explanation	For the Autoliv's airbag with the weight 1560 grams igniter granules were needed in amount of 1.24 gram.
Process Type	Unit operation
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	Igniter granules consist of the explosive material guanidine nitrate and the oxidizer potassium nitrate. They are placed in the inflator and when the crash occurs, the sensors from the car send the signals to the Airbag Control Unit, from where the signals go to initiator. The initiator creates electrical impulses and produces high temperature in order to make the explosive material explode. The explosion can occur thanks to the oxidizer that is stored close to the guandine nitrate. The nitrogen gas fulfills the cushion which protects the occupant against hitting the steering wheel or other parts in the car. Manufacturing process description is not available due to confidentiality. This process is included in the system described in: Mujiyanto A., Priyojati S. (2010). Life cycle assessment of Autoliv's Driver Airbag. Master thesis report. ESA report 2010:1, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. SPINE LCI dataset: Airbag's inflator assembly. Autoliv ESA-DBP

Administrative	
Finished	Y
Date Completed	2010-07-08
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Airbag's inflator assembly. Autoliv ESA-DBP
Functional Unit	1 unit of inflator
Functional Unit Explanation	1 airbag inflator weighs 666.34 grams and it is a part of the airbag which weighs 1560 grams
Process Type	Unit operation
Site	Autoliv IRO. Brasov, Romania.
Sector	Manufacturing
Owner	Autoliv IRO. Brasov, Romania.
Technical system description	The inflator is the part of the airbag responsible for airbag deployment. In this part gas generant, initiator and many other components are placed. When a crash occurs, the sensors from the car send the signals to the Airbag Control Unit, from where the signals go to initiator. The initiator creates electrical impulses and produces high temperature in order to make a gas generant explode. The gas fills the cushion and protects the occupant against hitting the steering wheel or other parts in the car. In addition to initiator and gas generant, the inflator consists also of: diffuser, base, adapter, seal washer, igniter tube, cup, cap, filter, pad damper, retainer disk, caution label and clinching stud. It weighs 666.34 grams. The inflator is assembled in Autoliv Romania. The process consists of the following steps: 1. Welding some metal parts 2. Pouring the gas generant 3. Leakage check by using helium 4. Electrical check 5. Putting the labels This process is included in the system described in: Mujiyanto A., Priyojati S. (2010). Life cycle assessment of Autoliv's Driver Airbag. Master thesis report. ESA report 2010:1, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Technical System	
Name	Airbag's initiator assembly. Autoliv ESA-DBP
Functional Unit	1 unit of initiator

Functional Unit Explanation	1 initiator weighs 11.044 grams while the airbag weighs 1560 grams.
Process Type	Unit operation
Site	Autoliv ITO. Tremonton, Utah, US.
Sector	Manufacturing
Owner	Autoliv ITO. Tremonton, Utah, US.
Technical system description	The initiator is a part of the airbag and it is placed in inflator. When the crash occurs, the sensors from the car send the signals to the Airbag Control Unit, from where the signals go to initiator. The initiator creates electrical impulses and produces high temperature in order to make a gas generant explode. The gas fills the cushion which protects the occupant against hitting the steering wheel or other parts in the car. The initiator is assembled in Autoliv in US and transported to Autoliv Romania. It consists of overmoulding, bridgewire, cruciformed cup, ignition fuel, insulation cover, chargeholder and header. It weighs 11 grams. The process consists of the following steps: 1. Drying the propellants 2. Welding the bridgewire to header 3. Welding the chargeholder to bridgewire 4. Loading the propellant 5. Welding the cup 6. Installing the cover over the cup 7. Check and inspection 8. Overmoulding This process is included in the system described in: Mujiyanto A., Priyojati S. (2010). Life cycle assessment of Autoliv's Driver Airbag. Master thesis report. System Boundaries

Nature Boundary	The performed study is an unit operation. It starts with processing the materials from the suppliers and ends with dispatching to Autoliv Romania. Data given by Autoliv US do not show any emissions.
Time Boundary	Data were acquired in 2009.
Geographical Boundary	Manufacturing plant is located in USA.
Other Boundaries	Excerpt from the report, see 'Literature reference': ''Maintenance of production capital as well as personnel related environmental impacts were excluded from the study. Transportation within the production plant was not included.''
Allocations	The allocation procedure was applicable in case of electricity and water consumption. Those values were given for the annual production. Allocation was based on the value on annual production and value of studied product.
Systems Expansions	Not applicable

About Inventory	
Publication	Mujiyanto A., Priyojati S. (2010). Life cycle assessment of Autoliv's Driver Airbag. Master thesis report. ESA report 2010:1, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: a href=http://cpmdatabase.cpm.chalmers.se/DataReferences /ESA_2010--1.pdf>http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2010--1.pdf
Intended User	LCA practitioner
General Purpose	Autoliv has decided to perform 4 LCA projects for the following products: airbag, seatbelt, night vision camera (NVC) and electronic control unit (ECU). The main purpose was to learn more about the products and their environmental performances and eventually decrease their impact on the environment.
Detailed Purpose	The discussed initiator is the part of the airbag which was the object of the study. The main goals of the study are: (excerpt from the report, see 'Literature reference') ''1. To identify the environmental impacts that can be associated with the airbag. 2. To analyze several environmental impacts such as consumption of different resources, e.g. energy, water, materials, etc., emissions of specific pollutants such as CO2, NOx, SO2, etc. and amount of generated wastes. 3. To determine the relative environmental load of the airbag package compared to a complete car. 4. To determine whether there are materials in the product that should be avoided for environmental reasons.''
Commissioner	Autoliv Development AB - .
Practitioner	Arief Mujiyanto & Susetyo Priyojati - .
Reviewer	Birgit Brunklaus & Henrikke Baumann -
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Year 2010. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: the Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environemental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	In the study it was assumed that the scenario for the end of life is that the airbag is shredded together with the car. Before that it has to be deployed in the specialized garage. The assumption made in the project says that 80% of the airbag will be recycled. The rest consists mainly of resins, rubber, glass, textile etc. The studied product is a part of the airbag which was the object of the LCA study for Autoliv. More processes from the same study were also documented in this database. In parallel to the airbag, 3 other LCA studies for Autoliv were carried out (for seatbelt, night vision camera and electronic control unit). Some of the processes can be found also in the CPM

	database.

SPINE LCI dataset: Airbag's label manufacturing. Autoliv ESA-DBP

Administrative	
Finished	Y
Date Completed	2010-07-08
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Airbag's label manufacturing. Autoliv ESA-DBP
Functional Unit	1 label
Functional Unit Explanation	1 label weighs 1 gram while airbag weighs 1560 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	The label is used for attaching information to the product. This particular label is attached to an airbag, produced by Autoliv. It is made of polyethylene and it weighs 1 gram. The manufacturing process of label takes place in Sweden and consists of the following steps: - preparing the polyethylene film by extruding polyethylene granule with extrusion molding machine - cutting the film among the edge - adding the adhesive to the surface of the film - printing information on the label This process is included in the system described in: Mujiyanto A., Priyojati S. (2010). Life cycle assessment of Autoliv's Driver Airbag. Master thesis report. ESA report 2010:1, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. SPINE LCI dataset: Airbag's nut manufacturing. Autoliv ESA-DBP

Administrative	
Finished	Y
Date Completed	2010-07-08
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Airbag's nut manufacturing. Autoliv ESA-DBP
Functional Unit	1 nut
Functional Unit Explanation	1 nut weighs 1.7 gram while the whole airbag weighs 1560 grams. 4 nuts are needed for 1 airbag.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	The nut is used for fasting components. In case of Autoliv's airbag 4 nuts are used during the installation of the airbag in the steering wheel. They are made of steel and coated with zinc. The weight of each is 1.7 gram. The nuts' supplier is located in Sweden but the production takes place in Taiwan. The manufacturing process consists of the following steps: 1. Cutting the steel bar 2. Threading with the tapping machine 3. Zinc coating This process is included in the system described in: Mujiyanto A., Priyojati S. (2010). Life cycle assessment of Autoliv's Driver Airbag. Master thesis report. ESA report 2010:1, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. SPINE LCI dataset: Airbag's shunt ring. Autoliv ESA-DBP

Administrative	
Finished	Y
Date Completed	2010-07-08
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Airbag's shunt ring. Autoliv ESA-DBP
Functional Unit	1 unit of shunt ring
Functional Unit Explanation	1 shunt ring weighs 0.4543 gram and is a part of the airbag which weighs 1560 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	The shunt ring is a part in the airbag's inflator which stabilizes the initiator. There are 2 shunt rings in the studied inflator; one green and one purple. They have the same content and they weigh 0.45 gram. They might be used in other products as well for example for stabilizing purpose. Shunt rings are produced in Germany. The manufacturing process starts with injection molding. In parallel the pin is produced from copper alloy which is coated with gold and nickel. In the end of the process the pin is attached to the ring. This process is included in the system described in: Mujiyanto A., Priyojati S. (2010). Life cycle assessment of Autoliv's Driver Airbag. Master thesis report. ESA report 2010:1, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. SPINE LCI dataset: Air-conditioning system. ESA-DBP

Administrative	
Finished	Y
Date Completed	2007
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Air-conditioning system. ESA-DBP
Functional Unit	Air-conditioning system which conditions and distributes a variable airflow volume (VAV) of a max. 5 m3/s
Functional Unit Explanation	Excerpt from the report, see 'Publication': ''The air-conditioning system includes the cooling and the air distribution systems. The required temperature of the supply is 15 °C all during the year, and the room temperature varies from 20 °C to 25.5 °C. The system operates for 11h (7am-18pm) each working day, 5 days a week. The lifesplan of this system as an entity is estimated to be 15 years.'' The data are valid for 1 year.
Process Type	Cradle to gate
Site	Unknown
Sector	Goods and services for households

Owner	Unknown
Technical system description	Schematics of the system can be found in the reference report (see 'Publication'). This particular air-conditioning system was used for comparison with bore-hole system (see 'Bore-hole based air-conditioning system. ESA-DBP'). The discussed system was (excerpt from the report, see 'Publication') '' designed to meet the same requirements, but with more traditional sources for heating (district heating) and cooling (refrigeration). ''The air-conditioning system studied was installed to provide a building complex with ventilating air which should also lead off the surplus heat from the premises. (...) The gross area of the premises is 5000 m2, or 2500 m2 for each of the buildings. (...) The system (...) consists of an air-handling unit, an air distribution system(...). The source of cooling energy is, in this particular system, an ordinary chiller. Calculations of materials and energy use for the two air-conditioning systems are based on the design documents for system A (NB: bore-hole system), since both system alternatives are designed for the same building. (...) Although the disposition of the storeys differs slightly, for the estimation of the energy use, they are assumed to be similar. The total net area of the buildings is 1920 m2, which is mostly divided into cell offices and an auditorium for 150 persons. The total internal loads are assumed to be 40 W/m2, accounting for 10 W/m2 for people, and 15 W/m2 each for lighting and computerised equipment. (...) The production stage includes the assembly of the air distribution system in the building. User stage of the life cycle includes electricity for operation of the air-handling unit and the cooling system, required heat energy, and the leakage of the refrigerant. (...) Electricity amounts for operation of the air-handling units are estimated by using a specific fan power (SFP) factor of 1.1 kW/(m3/s) when distributing 80% of the maximum airflow, which corresponds with an SFP of 2.1 for the maximum airflow. Air is distributed in the building via a novel construction of a VAV supply air volumes at low air temperatures, 15 °C and lower, without a draught problem. (...) The environmental impacts of the disposal stage are calculated for material recycling (metals 95%, polyethylene 90%), for inineration with energy recovery (100% of the other plastics, 10% of polyethylene), and for land-filling (5% of all metals, 100% of the mineral wool insulation). Main assumptions made for this study are (NB: based on the comparative table): all-air; vapour compression; variable airflow; air-conditioning system; life cycle phases: production, user, disposal; office area: 1920 m2; total airflow: 5 m3/s; supply air temperature: 15°C, exhaust air temperature 22.5 °C; internal heat loads 40 W/m3; cooling loads: 124 MWh/year; operating time: 8760 h/year, SFP: 1.1 kW/(m3/s), life span: 15 years. This process is included in the system described in: Heikkilä K. (2007). Environmental Assessment of Air-conditioning Systems. Design Considerations for Swedish Conditions. Report no. D 2007:2, Department of Building Services Engineering, Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/Heikkila_et_al_2007 Other processes in the CPM Database also included in the above publication: - Bore-hole based air-conditioning system. System Boundaries

Nature Boundary	In the study production, user and disposal stages are considered. The inventory analysis included parameters describing resource use and emissions to air and water.
Time Boundary	2005
Geographical Boundary	Göteborg, Sweden
Other Boundaries	Excerpt from the report, see 'Publication': ''The environmental impact (...) is analysed by taking into account the production of materials that comprise them, the energy use for the operation of the systems, and their eventual removal. The air distribution system in the building is also included in the analysis. During the lifespan of each system, supply and exhaust air filters have to be replaced according to a predefined time schedule. As shown in earlier studies, the impact of the filter materials and their amounts (mostly sheet steel and rock wool) on the environmental performance of the whole system is negligible. Therefore, these material amounts are excluded from this analysis. Moreover, components such as silencers, dampers, various valves and screws are also excluded. Neither the transports of materials to the producers, nor to the building site, are taken into account according to the assumption that the transportation distance is equivalent for both systems and would thus not affect results.''
Allocations	Unknown

Intended User	LCA practitioner
General Purpose	Excerpt from the report, see 'Publication': ''An objective of this work was that it should lead to an increased knowledge of how to work with environmental issues related to air-conditioning systems for office buildings and to a greater awareness of the environmental loads related to these systems. (...) The objectives of this thesis are to: - describe how the environmental performance of air-conditioning systems can be assessed and evaluated at the design stage. The focus is on the application of existing methods for environmental assessment of these systems. - identify and discuss the major sources of the environmental impacts and give some general recommendations as to how to design air-conditioning systems to improve their

	environmental performance. - outline possible key performance indicators (KPI) for the environmental performance of the most common types of air-conditioning systems.''
Detailed Purpose	Excerpt from the report, see 'Publication': ''Case study analyses environmental impacts related to two all-air systems with different means of cooling. One of the systems uses mainly boreholes in the ground for cooling the supply air. This system is compared to a traditional reference system that uses a chiller for conditioning the supply air.''

Technical System	
Name	All-air air handling unit with a cooling coil and vapour compression chiller with a refrigerant. ESA
Functional Unit	''One air handling unit, which distributes a constant airflow volume (CAV) of 4.8 m3/s 24h a day for 15 years.''
Functional Unit Explanation	Excerpt from the report, see 'Publication': ''The required temperature of the supply air is constant of 16°C and the room temperature varies between 20°C and 25°C.'' The data are valid for 1 year.
Process Type	Cradle to grave
Site	Unknown
Sector	Goods and services for households
Owner	Unknown
Technical system description	Schematics of the system can be found in the reference report (see 'Publication'). The studied product is (excerpt from the report, see 'Publication') ''an all-air, air handling unit with a cooling coil. A vapour compression chiller with a refrigerant completes the installation. (...) Calculations are based on a case study of an office building. The 15-storeyed building is

	designed to be situated in Stokholm, Sweden. The storeys are designed to be similar and the offices are allocated 5000 m2 of the total area of 12500 m2. The total internal loads of the offices are 33 W/m2, accounting for 33 occupants per floor (10 W/m2). Each office room has an area of 10 m2, a room height of 3 m, and outer wall space 6.6 m2, of which the window area is 4.4 m2. Although four air handling units of the same size and construction for each alternative serve the whole building, the materials and energy amounts (...) are based on calculations for one air handling unit. (...) As an entity, the life cycle of the systems is assumed to be 15 years. Occasionally, the systems must be changed or rebuilt sooner because of changes of occupants or in the use of the building. Accordingly, it would be unrealistic to assume a lifetime of more than 15 years. For the user stage of the life cycle, electricity amount (...) is calculated by using specific fan power factor (SFP) of 2.5kW/(m3/s) (...). The energy use for the compressor of the chiller (...) is calculated for 30800 kWh cooling loads per year, using the seasonal performance conditions for the chiller over a full year. (...) There is no need for heating of the supply air during the cold part of the year because of the low temperature of supply air (16°C) and the high efficiency of the heat recovery unit (74%). (...) The hourly measured weather data for the year 1990 in Stokholm, Sweden are used in the calculations. The year 1990 was chosen because the number of hours with ambient air temperatures of 16°C or more corresponds to the 10-year mean value for the period 1982-1992. The user stage of the life cycle also includes the environmental impact of the filters for supply and exhaust air (...) as well as leakage of the refrigerant. The lifetime of the filter is assumed to be one year, and the annual leakage ratio is 2% of the refrigerant charge. The environmental impact of the disposal stage is calculated for material recycling, for incileration with energy recovery and for landfilling.'' Main assumptions made for this study are (NB: based on the comparative table): all-air; constant airflow; air-handling unit; life cycle phases: production, user, disposal; office area: 1250 m2; total airflow: 4.8 m3/s; supply air temperature: 16°C, exhaust air temperature 25°C; internal heat loads 33 W/m3; 105 MWh/year; operating time: 8760 h/year, SFP: 2.5 kW/(m3/s), life span: 15 years. This process is included in the system described in: Heikkilä K. (2007). Environmental Assessment of Air-conditioning Systems. Design Considerations for Swedish Conditions. Report no. D 2007:2, Department of Building Services Engineering, Chalmers University of Technology. Gothenburg, Sweden. SPINE LCI dataset: Aluminium recycling by refiners

Administrative	
Finished	Y
Date Completed	2002-05-07
Copyright	EAA
Availability	Public

Technical System	
Name	Aluminium recycling by refiners
Functional Unit	1000 kg aluminium ingot
Functional Unit Explanation	Aluminium rolling or extrusion ingot
Process Type	Gate to gate
Site	Not specified. See Geographical boundaries for further information.
Sector	Materials and components
Owner	Not specified. See Geographical boundaries for further information.
Technical system description	This inventory data represents the model of used aluminium recycling practice in Europe, as operated by the aluminium refiners in an average recycling situation. The refining includes: - Scrap preparation - Melting and alloying Production of electricity is included in the system. The mix of technologies included is presented below, under the headline ''Scrap preparation'' and ''Melting and alloying''. The aluminium refiners recycle old aluminium scrap, their typical material input comprising one-third aluminium scrap from end-of-life aluminium products, the rest is new scrap i.e turnings, skimmings and dross, and aluminium metallics. Several melting processes are used. The choice of process depends upon a number of variables. These include the composition of the scrap, the process available within the given plant, and economic and scheduling priorities. A breakdown of the common melting technologies is given below, under the headline ''Information regarding secondary smelting furnaces''. Molten metal fluxing (to treat the molten metal: chemical adjustment, cleaning, yield maximisation, degassing, etc.) and filtration technology (to remove any unwanted materials prior to casting) has been developed to produce aluminium alloys of the correct quality without undue environmental impact. ----------Scrap preparation-------------------- The scrap is sorted in the following categories: 1. shredder sheet scrap (4%) 2. shredder cast scrap (6%) 3. sink and float (9%) 4. baling (15%) 5. skimmings treatment (16%) 6. turnings treatment (50%)

	--- Specification of the scrap --- OLD SCRAP Old scrap is the aluminium material which is recovered after an aluminium article has been produced, used and finally collected for recycling. Old scrap could be a used aluminium bevarage can, a car cylinder head, window frames, or electrical conductor cable. Old aluminium scrap comes into the secondary industry via a very diversified and efficient network of metal merchants and waste management companies which have the technology to recover aluminium from vehicles, household goods, etc. This is often done using heavy equipment such as shredders, thogether with magnetic separators to remove iron, sink-and-float installations, or by the use of eddy current installations to separate aluminium from other metals. NEW SCRAP New scrap is surplus material that arises during the production and fabrication of aluminium products up to the point where they are sold to the final customer. Thus extrusion discards, sheet edge trim, turnings, millings and drosses could all be described as new scrap. Most new aluminium scrap comes into the secondary industry directly from the fabricators. It is therefore of known quality and alloy, and is often uncoated. It can then be melted with little preparation, apart perhaps from baling. Some new scrap that arises during semi-finishing processes may be coated with paints, ink, or plastics. This scrap can be decoated by passing scrap through an oven or a mesh conveyer whilst hot gases are circulated through the mesh to volatilise or burn off the coating. ----------Melting and alloying-------------------- The scrap is melted in a secondary smelting furnace. Different furnaces are used for European aluminium scrap refining: 1. Rotary furnance 2. Sloping hearth furnance 3. Open well reverberatory furnance 4. Electric furnance and goes further to the process steps: 5. Holding furnance 6. Casting. Further details on the rotary furnace process step: Coated aluminium scrap is typically processed by aluminium refiners using a rotary furnance with a salt flux, yielding salt slag as a by-product. The reprocessing of salt slags to recover salt flux and aluminium oxide is part of the aluminium refiners' operations as it is carried out either by the refiner himself or by an independent reprocessing specialist. The temperature of the molten metal is adjusted and alloying additions may be made with a combination of primary metals, recovered metals and master alloys to ensure the correct chemical composition of the melt.

System Boundaries

Nature Boundary	--- BOUNDARIES VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- Cut-off criteria through out this inventory is basically relevance, as checked by the industry expert team monitoring the work and confirmed by reviewer I. Boustead. As a rough guideline ''less than 1% of total mass'' is applied for the inputs, i.e if the input is less than 1% of the total mass, then it is not included in the inventory table. The base for the choices of included inventory parameters is not further described in the EAA report.
Time Boundary	--- BOUNDARIES VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- The data derived from an industry survey from 1998 and includes literature data from reports dated 1998 and 1999.
Geographical Boundary	--- BOUNDARIES VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- It is not always explicit in the report where the different included process steps take place. Data may be acquired from outside of Europe, e.g. regarding ancillary materials. See litterature references (LitteratureRef) next to the flow table (FlowMetaData) for further information about the data sources for each process step.
Other Boundaries	See Nature boundaries for a specification of the cut-off criteria that has been applied.
Allocations	Allocations are not explicitly specified in the Environmental Profile Report 2000.
Systems Expansions	System expansions are not explicitly specified in the Environmental Profile Report 2000.

Flow Data

General Activity QMetaData

Date Conceived	1998 - 1999
Data Type	Derived, unspecified
Represents	Not relevant.
Method	RECYCLING OF USED ALUMINIUM This recycling model has has been prepared through a survey of aluminium refiners carried out in 1998, with an estimated coverage of 53%. The survey specifically covered secondary refiners of various sizes, ranging in output from <5 000 tpa to major facilities with production in excess of 50 000 tpa. The survey took into account the process technology, feedstock and products, along with the input and output of the various processes. Due to the individual nature of most secondary refining plants it is not possible to publish process-specific data without the risk of exposing commercially sensitive information, because a given site usually has a unique mix of feedstock, products and process technology. See Applicability for further information. --- GENERAL INFORMATION REGARDING ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- TRANSPORTS Transport energy and air emission data have been taken from SAEFL Environmental Series 250 (1998) ''BUWAL 250'', table 16.9 ELECTRICITY For all manufacturing operations, the consumption of fossil fuels and emissions linked to electricity production was calculated according to the UCTPE 94 electrical energy model as described in BUWAL 250. Emissions from combustion only, i.e. excluding the production of the fuel, have been considered where appropriate in order to make a direct comparision with the corresponding process emissions. Emission data for combustion came from a report prepared by EMPA for EEA (13 December 1997), showing the respective contributions of production and combustion of the fuels in 'BUWAL 250, table 16.9'. Although emissions from fuel combustion were often covered in the reporting from the industry survey, data calculated from BUWAL 250 were always used, in view of the fact that the survey results were not sufficiently reliable due to inconsistent use of conversion factors.
Literature Reference	---Recycling - Aluminium scrap terms and definitions: pr EN 12258-3 - Aluminium BREF note: document prepared for the EU Commission, 1999 ---Transport energy, and electricity use, and air emissions - SAEFL Environmental Series 250 (1998) ''BUWAL 250'', table 16.9 - EMPA report for EAA dated 27 April 1998, derived from Buwal 250 for national grid systems.
Notes	In this inventory profile it is possible to identify if the emission derives from the process or the energy use, see Note-field for each specific flow.

About Inventory

Publication	Environmental Profile Report for the European Aluminium Industry, European Aluminium Association, April 2000 -- Data documented by: Maria Erixon, IMI, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, IMI, Chalmers University of Technology Published in SPINE@CPM: 8 May 2002 --
Intended User	LCA-practitioners.
General Purpose	The European Aluminium Association (EAA) aims to contribute to further environmental improvements in aluminium products in a life cycle concept.
Detailed Purpose	The purpose with the Environmental Profile Report 2000 is to provide LCA-practitioners with detailed and up-to-date information representing the aluminium industry activities in Europe. The purposes with formatting the Environmental Profile Report 2000 for the European Aluminium Industry to the data documentation format SPINE, according to the data documentation criteria applied at Centre for environmental assessment of Product and Material systems (CPM) are: - CPM and European Aluminium Association (EAA) are anxious to provide life cycle assessment (LCA) practitioners with accurate and up to date environmental data for aluminium production. - EAA is interested in the SPINE formatting procedure and result, as the format is a base for (and therefor somewhat similar to) the new Technical Specification in ISO, ISO 14048, regarding LCA data documentation format. - EAA is interested in the CPM data quality control and documentation criteria.

Applicability	--- SPECIFIC INFORMATION FOR THIS DATA SET --- RECYCLING OF USED ALUMINIUM This recycling model has has been prepared through a survey of aluminium refiners carried out in 1998, with an estimated coverage of 53%. The survey specifically covered secondary refiners of various sizes, ranging in output from <5 000 tpa to major facilities with production in excess of 50 000 tpa. The survey took into account the process technology, feedstock and products, along with the input and output of the various processes. Due to the individual nature of most secondary refining plants it is not possible to publish process-specific data without the risk of exposing commercially sensitive information, because a given site usually has a unique mix of feedstock, products and process technology. For most scrap types there are several viable processing routes, which may be taken in order to meet specific company requirements. For a given scrap, each process route will have advantages and disadvantages. For example, one process route may produce higher metal yields, but at the cost of reduced flexibility, e.g. in the range of feedstock that could be used, higher investment in equipment or additional environmental controls. The aluminium refiners therefore actually make a case-by-case selection, depending on the type of scrap, through a range of pre-treatment, preparation and melting technologies, in order to maximise the metal value and to optimise the environmental aspects. As a result of this inherent variability in scrap processing for recycling, the aluminium recycling model developed here is only indicative, and this should be borne in mind if it is used to describe the recycling of any particular product. Any LCA-study on aluminium recycling would need to check carefully how well this fits with the particular aluminium product or process involved, in order to avoid misinterpretations or incorrect conclusions. ALUMINIUM RE-MELTING VERSUS PRIMARY ALUMINIUM PRODUCTION Aluminium re-melting requires much less energy than the primary aluminium production from its ore. A clear-cut comparision is not possible because the energy used in re-melting is predominantly thermal while being electrical in the electrolysis. However, aluminium re-melting saves raw materials and energy, and also reduces demands on landfill sites. --- GENERAL INFORMATION VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- RECOMMENDATIONS BY EAA WHEN USING THE DATA The data provided by the EAA members for their own process steps are the most up-to-date average data available for these processes, and it is recommended that they be used for LCA purposes. Older literature data should be disregarded, as it may no longer be representative due to technological improvements, progress in operating performance, changes with regard to raw materials or waste treatment, etc. To complete the product system inventory, data - on the production of consumer products, from semi-fabricated aluminium, - on the performance of consumer products in the use phase, and - on the recovery of scrap prior to remelting at the end of the product’s useful life should be acquired. EAA recommend that these data be used in LCA studies in accordance with methodologies within the framework of the international standards in the ISO 14040-series. RELATED DATA SETS IN SPINE DATA FORMAT The data presented in the Environmental Profile Report is reformatted in to the SPINE format and structured according to the SPINE concept in as many separate activities (sub-systems) as possible. The system scope for the study as a whole is primary aluminium production, semi-finished aluminium production, and recycling. The SPINE formatting resulted in 7 activities. These activities are all published in the SPINE@CPM database. The production and recycling step are intended to be used together. For example, to obtain a cradle to gate-system for rolled aluminium sheet, the activity Primary aluminium production should be connected to the activity Production of rolled aluminium sheet. A recycling step (Aluminium recycling by refiners) could also be connected to such a system, depending on the scope. -- List of activities formatted in the SPINE-format, published in SPINE@CPM -- Primary aluminium production 1. Primary aluminium production Semi-finished aluminium product fabrication 2. Production of rolled aluminium sheet 3. Production of extruded aluminium profiles 4. Production of 0,02-0,2 mm single-rolled aluminium foil 5. Production of 0,005-0,02 mm double-rolled aluminium foil Recycling 6. Re-melting of aluminium scrap 7. Aluminium recycling by refiners

	Please note: The recycling process 6. Re-melting of aluminium scrap is included in the semi-finished aluminium product fabrication, i.e. activities 2-5. When designing a product system with the activities above where recycled aluminium is regarded, the activity Aluminium recycling by refiners should be used. The Re-melting of aluminium activity is only a specification if the user is specifically interested in this process step. RECYCLING RATES FOR ALUMINIUM PRODUCTS AFTER USE After use, aluminium products are a valuable re-usable resource. The European recycling rates for end products are currently around 95% for the automotive sector and 85% for the building sector. IMPROVEMENTS IN THE ENVIRONMENTAL PERFORMANCE OF ALUMINIUM PRODUCTS AND PROCESSES OVER THE PAST FEW YEARS Over the past few years EAA has achieved major improvements in the environmental performance of its production processes by means of the following: - improvement on existing technology - development and introduction of new technology and operations - increased recycling of all materials in the production process. Examples of major environmental improvements in aluminium products achieved over the past few years include: - weight reduction by downgauging in the packaging sector - energy savings through weight reduction and subsequent fuel reduction in the transport sector - reduction of maintenance in the building sector The previous Ecological Profile Report from EAA was published in 1996.
About Data	--- GENERAL INFORMATION VALID FOR ALL DATA SETS FROM THE ENVIRONMENTAL PROFILE REPORT 2000 --- PRECISION According to EAA, the environmental data figures in the inventory table are usually accurate to a precision of 5%. DATA SOURCES FOR FUELS/ENERGY PRODUCTION AND COMBUSTION The electricity supply systems and fuel production and use (transport energy and emission data) have been taken from SAEFL Environmental Series 250 (1998) 'Buwal 250' and EMPA report for EAA dated 27 April 1998, derived from Buwal 250 for national grid systems. All emissions connected with total fuel consumption (i.e. production and combustion of oil, gas or coal) have been taken from SAEFL Environmental Series 250 (1998) 'Buwal 250', table 16.9. Emissions from combustion only, i.e. excluding the contribution of the production of the fuel, have been considered where appropriate in order to make a direct comparision with the corresponding process emissions. Emission data for combustion came from a report prepared by EMPA for EEA (13 December 1997), showing the respective contributions of production and combustion of fuels in 'BUWAL 250, table 16.9'. Although emissions from fuel combustion were often covered in the industry survey reporting, data calculated from BUWAL 250 were always used, in view of the fact that the survey results were not sufficiently reliable due to inconsistent use of conversion factors. REVIEW OUTSPOKE Ian Boustead has reviewed and commented on the Environmental Profile Report for the European Aluminium Industry, April 2000, which is a revision of the first Ecological Profile Report from EAA that were published in 1996. Ian Bousteds' review comments on the Environmental Profile Report for the European Aluminium Industry, April 2000: ''...I have received the detailed calculations on which this present environmental report is based. All of the queries that I raised after working through these reports were answered satisfactory.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000 ''Good-quality data were supplied by the EAA member companies, and the number of companies participating provides good coverage of the various processes, meaning that the results can be regarded as representative of the industryas a whole for the production of primary aluminium and subsequent conversion processes.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000 ''Because of the very fragmented nature of the recycling industry and wide variations in practices, it is recognised that the data presented for this sector of the industry can only be regarded as indicative. Nevertheless it is helpful to have such information from an authorative source.'' Ian Bousted, Environmental Profile Report for the European Aluminium Industry, April 2000
Notes	REVIEWER Ian Boustead has reviewed and commented on the Environmental Profile Report for the European Aluminium Industry, which is a revision of the first Ecological Profile Report from EAA that were published in 1996. See AboutData for review comments.

	GENERAL TECHNICAL INFORMATION ABOUT SECONDARY SMELTING FURNANCES Below some further information about the different types of furnaces and areas of application for secondary smelting furnances used in aluminium recycling. Furnance type: REVERBERATORY Variations: Standard, Side Well and Sloping Hearth STANDARD Principal application: Melting larger volumes of clean scrap and primary feedstock Advantages: Large metal capacity (<=100t), Few restriction on feedstock sizes, Lower salt slag use Disadvantages: Lower thermal efficiency, Restricted feedstock types Comments: High yields due to quality of feedstock, Molten metal pumps sometimes used SIDE WELL Principal application: Melting larger volumes of clean scrap and primary feedstock, Enables efficient recovery of some finer feedstocks Advantages: Large metal capacity, Wider range on feedstock possible, Normally no salt slag Disadvantages: Lower thermal efficiency Comments: High yields due to quality of feedstock, Molten metal pumps sometimes used SLOPING HEARTH Principal application: Separation of aluminium from higher melting point metal contamination (i.e. iron/steel) Advantages: Very efficient at removing high melting point contaminants Disadvantages: Lower thermal efficiency Comments: Sometimes incorporated into other furnance types, Yield dependent on level of contamination Furnance type: ROTARY Variations: Fixed Axis, Tilting FIXED AXIS Principal application: Recycling a wide range of feedstocks Advantages: No feedstock restrictions, Good thermal efficiency, Efficient de-magging, No skimmings produced, Large chargevolumes possible (<50t) Disadvantages: Relatively high usage of salt flux, Feedstock size may be restricted Comments: Resultant salt slags can be reprocessed TILTING Principal application: Recycling a wide range of feedstocks Advantages: No feedstock restrictions, Good thermal efficiency, Efficient de-magging, No skimmings produced, Large chargevolumes possible (<50t) and lower use of salt flux than ''Fixed Axis'' Disadvantages: Feedstock size may be restricted Comments: Tends to be used for lower scrap grades Furnance type: INDUCTION Variations: Coreless, Channel CORELESS Principal application: Melting of cleaner scrap or primary feedstock Advantages: High yields obtained, No combustion gases, No salt flux required, Flexible use (batch and continous processing possible) Disadvantages: Relatively small load (<10t), Restricted feedstock type, Feedstock size may be restricted Comments: - CHANNEL Principal application: Melting of cleaner scrap or primary feedstock Advantages: High yields obtained, No combustion gases, No salt flux required Disadvantages: Relatively small load (<20-25t), Restricted feedstock type, Feedstock size may be restricted Comments: -

SPINE LCI dataset: Anaerobic digestion of biological household waste. ESA-DBP

Technical System

Name	Anaerobic digestion of biological household waste. ESA-DBP
Functional Unit	1 ton of biological household waste
Functional Unit Explanation	The functional unit is 1 ton of dry substance biological household waste.
Process Type	Gate to gate
Site	
Sector	Waste treatment
Owner	
Technical system description	Biogas is produced when biological material is decomposed by methane producing bacteria during anaerobic conditions. These processes work in the temperature interval of 10 to 70 degrees Celsius. The most common process temperatures at biogas plants lies within the mesophilic range (around 35 degrees Celsius) or the thermophilic range (around 55 degrees Celsius) since the turnover of the bacteria is high at these temperatures. Thermophilic processes have become more and more common, since less volume for the anaerobic chamber is needed at higher temperatures. Wet processes are most abundant, but anaerobic digestion can also take place in dry processes. The process can be design in different ways depending on the type of substrate. One anaerobic digestion chamber is used in one-step processes, in two-steps processes chambers in series are used. When digesting sewage sludge different filters and carriers for microorganisms are used to optimize the process. Translated excerpts from the report (see 'Publication'): '' The biogas system consists of the digestion plants, waste deliveries and use of products. The waste transport to the plant is executed by waste collection vehicles driven with diesel or biogas. It is assumed that the cars go empty on the way back i.e. both there and back is accounted for. At the plant both biogas, solid digestion rest and liquid digestion rest are produced. Most of the biogas is sold to Trollhättan city for upgrading to vehicle gas. Some of the gas is distributed to the plants owngas net, from where the gas is sold to costumers for heating. Moreover some of the gas is used directly at the plant , or is burned as spill-over. The solid digestion rest is used to cover landfills at the plant, while the liquid digestion rest is used as fertilizer in agriculture. When the waste is digested it cannot be used for electricity- and heatproduction, as the case in the incineration alternative. To be able to compare the two different alternatives on an even basis emissions from equivalent production of electricity and heat from the Gothenburg District Heating plant are included.'' Processes included in the biogas system: - Anaerobic digestion plant (electricity from wind and water) - Upgrading and compressing - End use, light vehicles - End use, heacy vehicles - Waste transport with waste collection vehicle driven on diesel - Waste transport with waste collection vehicle driven on biogas - Combustion of biogas in a combustor belonging to the plant - Burning of spill-over biogas - Transport of and spreading of liquid digestion rest - District heating production - Electricity production, Swedish electricity mix Processes not included in the biogas system: - Leakage water - Solid digestion rest for covering of landfills - Methane leakage This process is included in the system described in: Ljungkvist H, 2008, Miljö- och samhällsekonomisk analys av behandling av biologiskt avfall. Environmental Systems Analysis report 2008:1, Chalmers University of Technology, Gothenburg, Sweden Link to pdf (in Swedish): http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2008--1.pdf Other processes in the CPM Database also included in the above publication: 'Incineration of of biological household waste. ESA-DBP'

System Boundaries

Nature Boundary	Not applicable.

Time Boundary	The documentor makes a qualified guess that the data was produced in the years 2006-2007, based on information in the report.
Geographical Boundary	The anaerobic digestion plant is located in Heljestorp, Västra Götaland, Sweden. Translated excerpts from the report (see 'Publication'): ''Waste transported from Trollhättan travelles 10 km one way with biogasdriven waste collection vehicles that need 7,3 m3 biogas per 10 km. The truck max load is assumed to be 8 tons.'' ''Waste from other municipalities (than Trollhättan) is assumed to travel in average 40 km to the plant, with dieseltrucks needing 3,5 liter diesel per 10 km. The truck max load is assumed to be 8 tons.'' ''The liquid digestion rest is transported 27,5 km one way to the agriculture and is spread in growing crop. The nitrogen evaporation is 5 percent.''
Other Boundaries	Translated excerpts from the report (see 'Publication'): '' The biogas system consists of the digestion plants, waste deliveries and use of products. The waste transport to the plant is executed by waste collection vehicles driven with diesel or biogas. It is assumed that the cars go empty on the way back i.e. both there and back is accounted for. At the plant both biogas, solid digestion rest and liquid digestion rest are produced. Most of the biogas is sold to Trollhättan city for upgrading to vehicle gas. Some of the gas is distributed to the plants owngas net, from where the gas is sold to costumers for heating. Moreover some of the gas is used directly at the plant , or is burned as spill-over. The solid digestion rest is used to cover landfills at the plant, while the liquid digestion rest is used as fertilizer in agriculture. When the waste is digested it cannot be used for electricity- and heatproduction, as the case in the incineration alternative. To be able to compare the two different alternatives on an even basis emissions from equivalent production of electricity and heat from the Gothenburg District Heating plant are included.'' Processes included in the biogas system: - Anaerobic digestion plant (electricity from wind and water) - Upgrading and compressing - End use, light vehicles - End use, heacy vehicles - Waste transport with waste collection vehicle driven on diesel - Waste transport with waste collection vehicle driven on biogas - Combustion of biogas in a combustor belonging to the plant - Burning of spill-over biogas - Transport of and spreading of liquid digestion rest - District heating production - Electricity production, Swedish electricity mix Processes not included in the biogas system: - Leakage water - Solid digestion rest for covering of landfills - Methane leakage ''The solid digestion rest is not included in the system because emissions from this are mixed with emissions to air and water from landfills.'' ''Storage of liquid digestion rest is excluded from the system.'' ''Usage of chemicals for maintenance of the plant is excluded from the system.'' ''The raw biogas from the plant is assumed to consist of 70 % methane.'' ''Leakage of methane when upgrading and compressing is assumed to be 2 %.''
Allocations	Not applicable.
Systems Expansions	Translated excerpts from the report (see 'Publication'): ''When the waste is digested it cannot be used for electricity- and heatproduction, as the case in the incineration alternative. To be able to compare the two different alternatives on an even basis emissions from equivalent production of electricity and heat from the Gothenburg District Heating plant are included.''

Publication	Ljungkvist H, 2008, Miljö- och samhällsekonomisk analys av behandling av biologiskt avfall. Environmental Systems Analysis report 2008:1, Chalmers University of Technology, Gothenburg, Sweden Link to pdf (in Swedish): http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2008--1.pdf
Intended User	LCA practitioners and employees at Ragn-Sells.
General Purpose	Master Thesis. Excerpt from the report (see 'Publication'): ''Biogas is a renewable fuel that can be extracted from anaerobic digestion of many different substrates, for example biological household waste. An alternative handling of the waste is to mix it with other wastes and incinerate it in a combined heat and power (CHP) plant. This study uses life cycle assessment to investigate which type of waste handling that is better from an environmental point of view, anaerobic digestion with biogas production or incineration. The results are based on a case study of a biogas production plant owned by the company Ragn-Sells in Vänersborg. The alternative is incineration at a CHP plant in Gothenburg.''
Detailed Purpose	These are the data for the anaerobic digestion process.

Applicability	For applicability for the process see 'Technical System' and 'System Boundaries'.
About Data	Translated excerpts from the report (see 'Publication'): ''Waste transported from Trollhättan travelles 10 km one way with biogasdriven waste collection vehicles that need 7,3 m3 biogas per 10 km. The truck max load is assumed to be 8 tons.'' ''Waste from other municipalities (than Trollhättan) is assumed to travel in average 40 km to the plant, with dieseltrucks needing 3,5 liter diesel per 10 km. The truck max load is assumed to be 8 tons.'' ''The liquid digestion rest is transported 27,5 km one way to the agriculture and is spread in growing crop. The nitrogen evaporation is 5 percent.'' '' Electricity and heat equivalent to what would be produced if the waste was burnt in a power plant is approximated with Swedish electricity mix and district heating production in Gothenburg.''

	'' Emissions from Swedish electricity production are based on LCA data including emissions from production and maintenance of plants.'' ____ ESA Database Project. Years: 2009-2011. Documentation completed for this data set: YYYY-MM-DD Administering organisation: Chalmers University of Technology, the division of Environmental Systems Analysis. Financier: The Swedish Research Council. Documentor of data: Filippa Fuhrman (ESA. Review committee for documented data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).

Availability	Public

Technical System	
Name	Australia, electricity generation mix 1998
Functional Unit	Total electricity produced during 1998
Functional Unit Explanation	The electricity mix refer to the total amount of electricity generated by different power sources expressed in GWh during the year 1998.
Process Type	Unit operation
Site	Australia
Sector	Energyware
Owner	Australia
Technical system description	The generation of electricity with different power generating systems in Australia during the year 1998.

System Boundaries	
Nature Boundary	Not applicable, since the data only refer to the electricity generation mix. The environmental load for generation of electricity is not included.
Time Boundary	The data refer to 1998.
Geographical Boundary	Only electricity produced in Australia is considered. Import or export of electricity is not included.
Other Boundaries	-
Allocations	Not applicable
Systems Expansions	Not applicable

Flow Data
General Activity QMetaData

Date Conceived	1998
Data Type	Derived, statistics
Represents	See 'Function'.
Method	The data are collected from IEA Statistics.

About Inventory

Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version

	- Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998

About Data	
Notes	--- --- Changes made to the data set after publishing in SPINE@CPM--- >>> 22 October 2001: <<< Changes made by Ann-Christin Pålsson, CPM: The electricity production by hydro power have been corrected from 1497 GWh to 389 GWh according to the original report. The error was identified and reported by Gunnar Mattson, ABB Corporate Research.

SPINE LCI dataset: Biofuel electricity energy system, EPD-version

Administrative	
Finished	Y
Date Completed	1996
Copyright	Bundesamt für Energie, Bern and Vattenfall AB respectively.
Availability	Public

Technical System	
Name	Biofuel electricity energy system, EPD-version
Functional Unit	1 TJ net electricity from power plant
Functional Unit Explanation	The generation of 1 TJ (1 000 000 000 000 J) net electricity (i.e. electricity need in the power plant has been supplied for by the plant istself). Electricity distribution and distribution losses are not accounted for.
Process Type	Cradle to grave
Site	Europe Unspecified
Sector	Grid electricity and district heat
Owner	Europe Unspecified
Technical system description	Reported figures are based on a combination of data from a LCI-study performed at ETH, Zürich and Paul Scherrer Institut, Villigen, ''Ökoinventare von Energiesystemen'', 3rd edition 1996 and of data from a LCI-study performed at Vattenfall AB, Life-cycle Assessment for Vattenfall's Electricity Generation, 1996 and adapted to the demands of the EPD-guidelines (Environmental Product Declaration guidelines in Sweden). . -- Brief description -- Data about the fuel chain i.e. fuel production and transports of fuel has been acquired from ETH and data about power plant operation has been provided by Vattenfall's study. The main phases inventoried in ETH's fir wood chips chain are: wood growth, forest care, light thinning of young forests and gathering of forest residues, transport by tractor to a nearby forest road, wood chipper, interim storage in containers, transport to combustion plant Data has been aquired from literature and figures concerning consumption of energyware and materials, use of land and water, emissions to air (also radioactive) and water and wastes have been picked out from or calculated based on literature for all phases of the life cycle.

	All subsystems are described on a ''cradle-to-grave'' basis, including the main stages, i.e. data concerning consumption of resources, waste handling and emissions is included for the manufacturing of main materials and energyware used in the lifecycle. -- Detailed description -- Forest growth The trees take CO2 from the air to grow and this has been reported as a negative emission of CO2. Construction of vehicles is included. Forest care Forest care includes construction of roads and bridges, the operation of tree-nurseries, planting, light thinning, clearing up after storms, hunt, protection against noxious animals etc. but only diesel consumption during planting, felling and road maintenance is included as well as area use. Felling Construction and diesel production and consumption of machines are included, from growing tree to forest road. Chipping Diesel production and consumption and construction of chipping machine is included. Transport Transport (22,5 km) with lorry (28 tonnes) from forest road to power plant is included. Power plant Only power plant operation emissions to air and ash amounts have been taken into account as well as fuel consumption. The power plant is a modern CFB (circulating fluidized bed), 9 MW with electro filter. Electric net efficiency has been set to 38% in accordance with stone coal fired plants. Condensing conditions are assumed. The fuel - wood chips (fir) - has an energy content of 4.6 MW/tonne dry substans (16.6 MJ/kg DS, 7.1 MJ/kg 50% humidity) and an ash content of 2% TS. Operation time 4400 h/year. Ashes are assumed to be deposited (no emissions from landfill included). Construction has been approximated with the construction of a 300 kW furnace (5000 h/year, 20 years lifetime). * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain.

System Boundaries	
Nature Boundary	ETH's study: Used materials and energyware have been followed from extraction and processing of natural resources. Manufacturing processes for the use of recycled material are accounted for. Emissions from energyware use in manufacturing processes and transports (infrastructure and vehicle construction included) are considered as well as emissions from landfills (infrastructure included) where waste material is disposed of. Waste material supposed to be recycled are outputs of the system (i.e. those recycling processes are not included). ETH's LCI-results comprise all parameters received during inventory and calculation, i.e. no selection has been made by ETH. Vattenfall's criterion in selecting and aggregating ETH's LCI-results for electricity generation in the UCPTE region has been to make the figures usable as general electricity LCI data in EPDs according to Miljöstyrningsrådets guidelines. Especially parameters (emissions) which have established impact indices - accepted by the EPD system - for one or several environmental impact categories, have been picked out and aggregated as far possible. But also metal and energyware resources have been included. Since ETH claimes that most of the figures regarding metal emissions have an undefined amount of datagaps all metal emissions are aggregated except for a few which are specified separatly since they are reported for most processes in the lifecycle. Metals are reported as elements although they often are part of compounds. Measuring methods often just give the amounts of the different elements found. All hydrocarbons to water are aggregated to one parameter as well as halogenated organics, since no indices exist (that are accepted by the EPD system so far) for characterisation of the individual substances. Vattenfall's study: Only the operation emissions to air of the studied plant and the amounts of ashes generated are included in this set of figures.
Time Boundary	ETH's study: Most background data refer to the period 1990 to 1994. Electricity used during the lifecycle has been assumed to be a mix based on the average

	generation in the UCPTE* countries between 1990-94 (to level off the large variations in hydro power production over the years). All processes, also those conducted in the past, have been assumed to use average technology of the early nineties. Different technical lifetimes/reference times for different parts and materials of the studied systems have been used as follows: Furnace 20 years Chips containers 15 years Trailer 20 000 h Tyres 2 500 h * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain. Vattenfall's study: The study embodies the lifetime of the studied plant, 40 years, but this has no impact on figures presented here since only figures regarding emissions and generated ashes per MJ fuel has been used.
Geographical Boundary	ETH's study: Figures are based on average lignite power plants in Austria, Germany, Spain, Ex-Jugoslavia, France and Greece. Lignite mining has been studied in the UCPTE since less than 1% is imported. 67% of lignite used in UCPTE is mined in Germany. Processes conducted outside the UCPTE* region are supposed to be supplied with UCPTE* electricity. Data concerning the use of resources, emissions and waste in connection with manufacturing processes mainly originate from sources in Switzerland, Germany and other western European countries. * Union pour la coordination de la production et du transport de l'életricité, following countries were members of the union in 1994: Belgium, Germany, France, Greece, Italy, Ex-Jugoslavia (Bosnia/Herzegowina, Croatia, Slowenia, and Rest-Jugoslavia), Luxemburg, Netherlands, Austria, Portugal, Switzerland, Spain. Vattenfalls study: no geographical boundaries regarding figures used in this study.
Other Boundaries	ETH's study: The buning of wood residues in the forest in connection with felling has not been included. Manufacturing processes of components and machines have been approximated with 50% of the energyware used to produce contained materials. Energyware figures concerning material production come from literature and have assumed to be a mix of 10% UCPTE electricity, 45% oil and 45% natural gas. This approximation has been confirmed in more thorough calculations in ETH:s LCA for coal power. The ETH study comprises figures concerning use of land, usable content in water storages and amount of turbine water which have not been reported here. The two latter have been excluded due to lack of corresponding data in comparable studies. Use of land has been excluded because of ETH's advanced approach. Land is divided into two main groups - land and sea - which are subdivided into 4 categories each. Land Criterion Category Natural human impact not larger than other species' since the indutrial revolution I Modified human impact larger than other species', low degree of culivation II Cultivated human impact larger than other species', large degree of cultivation III Built upon dominated by buildings, roads, dams, mines etc. IV Category I is not used in the study. State of land before, during and after exploitation is of intererst. If a piece of land is used again after some kind of exploitation it will either end up in the same category or in a higher one. ETH takes into account not only the land used during the technical lifetime of the studied system but also during the construction phase and during the time it takes to restore the land. They express use of land in the unit m2year which is different from comparable Swedish studies (m2). See times for restoration of land below: From category IV to category III 5 years From category III to category II 50 years From category II to category I 100 000 years (For uranium mines the restoration time to category II is 80'000 years due to elevated radiation caused by long-living radioactive compounds.)

	ETH specifies about 160 radioactive isotopes emitted to air and water. Radioactive emissions reported here are picked out in accordance with SETAC working group report on data quality and data availability (to be published in 2001). Big accidents occuring seldomly are not included.The threshold is fixes at 10 accidents per year if one energy carrier/system (e.g. oil) would cover the entire primary energy demand of the world. Vattenfall's study: no other boundaries regarding figures used in this study.
Allocations	ETH:s study: Allocation between the different products of the forest has been conducted according to the volume of the different products. The cutoff-method has been used for material use, i.e. 100% of the environmental load for virgin and recycled material used in the lifecycle is included whereas no environmental load has been considered for materials leaving the system to be recycled. Landfill processes and waste incineration, however, are included for waste arising during the lifecycle. Vattenfall's study: No allocation has been made, condensing conditions in the power plant is assumed, i.e. generated electricity bears all emissions.
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1985 to 1995
Data Type	Derived, unspecified
Represents	Approximate electricity generation with biofuel in modern power plant in Europe.
Method	The data has been adapted from the Ökoinventare von Energiesystemen, ETH Zürich 1996 concerning biofuel production (aggregation of the LCI results for the modules ''Holzschnitzel Fichte frei Lager'' per tonnes dry substance (0,0166 TJ/tonnes DS), ''Transport LKW 28 t'' per tkm (2 x 22,5 tkm (back and forth)) and ''Infra Feuerung Fichte 300'' per piece (electricity production 108 TJ/lifetime i.e. 300 kW, 5000 h/year, 20 years). Electric efficiency of power plant (condensing conditions assumed) has been set to 38% in accordance with stone coal fired power plants. Data about power plant operation has been taken from Vattenfall's LCA study of a bio-fuelled CFB plant (circulating fluidized bed).

About Inventory

Publication	Ökoinventare von Energiesystemen, Grundlagen für den ökologischen Vergleich von Energiesystemen und den Einbezug von Energiesystemen in Ökobilanzen für die Schweiz. ETH, Eidgenössische Technische Hochschule, Zürich, Gruppe Energie - Stoffe - Umwelt (ESU), Paul Scherrer Institut, Villigen/Würenlingen, Sektion Ganzheitliche Systemanalysen Available on CD-ROM with full documentation (in German) at http://www.energieforschung.ch. Life-cycle Assessment for Vattenfall's Electricity Generation, Summary Report, B-M Brännström-Norberg et al, 1996 -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by (see also Notes): Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	Original studies of ETH and Va
General Purpose	The purpose of the ETH study was to examine a number of energy systems quantitatively and to the same extent with respect to environmental issues during their life cycles. The results can be used in life cycle assessments, as basis information in decisionmaking regarding environmental optimisation or in working with municipal energy plans. Vattenfall's purpose with LCA for their electricity generation was to provide customers with data about the environmental impact of the electricity they buy, to create a basis for comparisons

	between energy systems and for decisions about future energy systems Vattenfalls purpose - as a commissioner of putting ETH:s data (and in this case also Vattenfall's data) into Spine format with metadata - is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines. Data is supposed to be used together with IEA statistics about electricity generation mixes in the OECD countries/regions.
Detailed Purpose	ETH:s aim was to describe the average situation in Switzerland concerning heat generation with different kinds of wood fuel. With the help of assumptions and simplifications following phases of the life cycle are described: forestry, felling (light thinning), chipping, transports, storage and furnace. (In this set of figures furnac operation is excluded and replaced by a power plant from Vattenfall's LCA). Vattenfall's aim was to describe the environmental impact of biofuel-based electricity generation. A specific plant was analysed concerning gathering of forest residues, chipping, transports, power plant construction, operation and maintenance and demolition and the handling of ashes. (Here, in this set of figures, only the operation phase of plant has been included.)
Commissioner	BEW, PSEL, Vattenfall - Bundesamt für Energiewirtschaft, Projekt- und Studienfonds der Elektrizitätswirtschaft, Bern, Switzerland Vattenfall AB, Stockholm, Sweden .
Practitioner	Rolf Frischknecht et al, B-M Brännström-Norberg et al - ETH, Eidgenössische Technische Hochschule, Institut für Energietechnik, Zürich and Paul Scherrer Institut, Sektion Ganzheitliche Systemanalyse, Villingen/Würenlingen Vattenfall AB .
Reviewer	None, see further under notes -
Applicability	Data reported here is supposed to be a approximation of bio-fuelled (wood chips from light thinning) elctricity generation in CFB plants in Europe. This set of data is aggregated and documented in accordance with the Swedish EPD-guidelines to be used in combination with IEA statistics concerning electricity generation mixes in OECD countries and regions together with other datasets - based on the ETH study - describing other power generation systems. The EPD-adapted power generation systems in Spine format are named as follows: Fuel gas electricity energy system, EPD-version Biofuel electricity energy system, EPD-version Hydro electricity energy system, EPD-version Lignite electricity energy system, EPD-version Nuclear electricity energy system, EPD-version Stone coal electricity energy system, EPD-version Wind electricity energy system, EPD-version IEA statistics for generation mixes 1998 exist in Spine format for the following 30 countries/regions: OECD total OECD North America OECD Pacific OECD Europe European Union Australia Austria Belgium Canada Czech Rpublic Denmark Finland France Germany Greece Hungary Iceland Ireland Italy Japan Korea Luxembourg Mexico Netherlands New Zealand Norway Poland Portugal Spain Sweden Switzerland Turkey United Kingdom United States

About Data	ETH's study: The reliability of data describing the felling process is quite good but is only valid for light thinning. Since smaller plants need more construction material per energyware produced than larger plants the construction phase of power plant is overestimated. On the other hand power plants are more complicated and need more material than heating-plants. I.e. the construction is a very rough approximation but the environmental impact is probably overestimated. Material manufacturing processes have been inventoried with a low degree of exactitude (except for steel, cement, aluminium, copper, bitumen, and platinum group metals for which rather detailed LCI data are provided. Results are reported with three figures, but it is stated in the original source that this does not mean that accuracy is that high (Part III, p.16). Vattenfalls's study: Results are reported with three figures, but it is stated in the original source that this does not mean that accuracy is that high. For references and sources of reported figures see further under Function, Nature boundary, Geographical boundaries, Publication, Notes and General metadata.
Notes	Reviewer of this specification of ETH:s data and metadata has been: Ann-Christin Pålsson, CPM - review of documentation quality according to the CPM data documentation requirements. The technical committee of the Swedish Environmental Management Council - approval of method and aggregation of parameters Project Management of the ETH study, 3rd edition: Professor, Dr. P. Suter and R. Frischknecht, ETH Editorial staff of the 1st edition: R. Frischknecht, P. Hofstetter, I. Knoepfel, M. Ménard, ETH R. Dones, E. Zollinger, Paul Scherrer Institut Authors of the 1st edition: N. Attinger, T. Baumann, G. Doka, R. Dones, R. Frischknecht, H.-P. Gränicher, C. Grasser, P. Hofstetter, I. Knoepfel, M. Ménard, H. Müller, M. Vollmer, E. Walder, E. Zollinger Authors of the überarbeitung, 3rd edition: U. Bollens, S, Bosshart, M. Ciot, L. Ciseri, G. Doka, R. Frischknecht, R Hischier, A. Martin, ETH R. Dones, U. Gantner, Paul Scherrer Institut Vattenfall's LCA has been reviewed by Tomas Ekvall, Chalmers Industriteknik and Lars-Gunnar Lindfors, IVL. --- --- Changes made to the data set after publishing in SPINE@CPM--- >>> 6 June 2001: <<< Changes made by Ann-Christin Pålsson, CPM based on discussions with Caroline Setterwall, Vattenfall AB. Comments: The following changes has been made in the nomenclature for in- and outflows: Mangane in ore -> changed to: Manganese in ore CH4 -> changed to: Methane (to be in accordance with the nomenclature specified in CPM report 2000:2) CN -> changed to: CN- Stone coal -> changed to: Hard coal (to be in accordance with the nomenclature specified in CPM report 2000:2) Other metals -> changed to: Metals Explanations of nomenclature (inserted in Notes for the specific flows): - CN- is Cyanide ion - Reactive waste deposit is waste at landfill that is still reactive. - Inert waste deposit is waste at landfill that are inert. Additional clarifications: - Note that the flows of waste in the table of in- and outflows are internal flows, i.e. they do NOT cross the system boundaries. All waste handling processes is included in the study with respect to use of resources and emissions. - Radioactive waste is accounted for in cubic metres. The product specific requirements for electricity and district heating generation (PSR 1998:1) in the Swedish EPD system states that waste shall be accounted for in gram. However, no conversion factors were given in the study. There are also no general conversion factors that are commonly used.

SPINE LCI dataset: Biogas from household waste, cradle-to-gate, no allocation - f3 fuels

Administrative	
Finished	Y
Date Completed	2013-11-30
Copyright	f3 - Swedish Knowledge Centre for Renewable Transportation Fuels
Availability	Public

Technical System	
Name	Biogas from household waste, cradle-to-gate, no allocation - f3 fuels
Functional Unit	1 MJ
Functional Unit Explanation	1 MJ output of biogas from household waste
Process Type	Cradle to gate
Site	
Sector	Fuel
Owner	
Technical system description	This dataset represents a model of the cradle to gate production of Biogas from household waste valid for southern Sweden. The following process are covered: - Collection of the waste - Anaerobic digestion of the waste - Transport and distribution of digestate. All electricity input in the production is Swedish grid mix. Fuel used at the biogas plant for heating are biogas from the plant it self. Allocation is made based on energy content (only case showed in Miljöfaktaboken, since this allocation method is preferred by the Renewable Energy Directive), however a case with system expansion is made in Börjesson et al. which also has been published in the f3 database. Transport distances are estimated based on southern Sweden conditions. The study is based on BAT (Best available technology). Capital goods are not included. Impacts from production buildings and infrastructure are not included.

System Boundaries	
Nature Boundary	
Time Boundary	2010 - 2013
Geographical Boundary	Southern Sweden.
Other Boundaries	
Allocations	The outputs from the anaerobic digestion are biogas and digestate. Emissions and primary energy demand are all allocated to the biogas. 100 % of the process outputs are thus allocated to the biogas.
Systems Expansions	No.

Flow Data

Technical System

Name	Biogas from household waste, cradle-to-gate, system expansion, impact categories only - f3 fuels
Functional Unit	1 MJ
Functional Unit Explanation	1 MJ output of biogas from household waste
Process Type	Cradle to gate
Site	
Sector	Fuel
Owner	
Technical system description	This dataset represents a model of the cradle to gate production of Biogas from household waste valid for southern Sweden. The following processes are covered: - Collection of the waste - Anaerobic digestion of the waste - Transport and distribution of digestate. All electricity input in the production is Swedish grid mix. Fuel used at the biogas plant for heating are biogas from the plant it self. Transport distances are estimated based on southern Sweden conditions. The study is based on BAT (Best available technology). Capital goods are not included. Impacts from production buildings and infrastructure are not included. Data in Börjesson et al. are only published as impact categories and not as emissions except for particles.

Name	Biogas from sugar beets, cradle-to-gate, no allocation - f3 fuels
Functional Unit	1 MJ
Functional Unit Explanation	1 MJ output of biogas from sugar beets
Process Type	Cradle to gate
Site	
Sector	Fuel
Owner	
Technical system description	This dataset represents a model of the cradle to gate production of biogas from sugar beets valid for southern Sweden. The following process are covered: - Cultivation of the sugar beets - Harvest - Distribution to the fuel plant - Production of biogas The mineral fertilizer used is assumed partly to be produced in Western Europe (about 60 %) with present level of cleaning equiptment etc., and partly imported from countries outside Europe (about 40 %). This implies that about 30 % of the mineral fertilizer production takes place in plants with nitrous oxide cleaning where the nitrous oxide emission levels are reduced with about 80 %. All electricity input in the ethanol-plant is Swedish grid mix. Fuel used at the biogas plant for heating is biogas from the plant itself. Allocation is made based on energy content (only case showed in Miljöfaktaboken, since this allocation method is preferred by the Renewable Energy Directive), however a case with system expansion is made in Börjesson et al. which also has been published in the f3 database. Transport distances are estimated based on southern Sweden conditions. The study is based on BAT (Best available technology). Capital goods are not included. Impacts from production of buildings and infrastructure are not included.

SPINE LCI dataset: Biogasification of solid municipal waste

Administrative

Finished	Y
Date Completed	2002-08-14
Copyright	McDougall F. et al, Integrated Solid Waste Management
Availability	Public

Technical System	
Name	Biogasification of solid municipal waste
Functional Unit	1 tonne of biowaste
Functional Unit Explanation	1 tonne of biowaste contains non-recyclable paper (15%) and wet organic waste (85%). Figures based on O.E.C.D, Environmental Data Compendium, Organisation for Economic Cooperation and Development. Paris, 1997.
Process Type	Gate to gate
Site	Europe
Sector	Waste treatment
Owner	Europe
Technical system description	Biogasification is an anaerobic metabolism, i.e. it occurs in the absence of oxygen. Through this anaerobic process biowaste (non-recyclable paper and organic waste) is transformed to compost, biogas and refining residue. It involves both consumption of energy during processing and production of useful energy as biogas. In this LCI model it is assumed that the biogas is burned on-site for power generation, and that surplus energy is exported as electrical energy. Anaerobic treatment of organic material is basically a two-stage process; large organic polymers are fermented into short-chain volatile fatty acids. These acids are then converted into methane and carbon dioxide. Condition for biogasification need to be anaerobic, therefore a totally enclosed process vessel is required. There are wet and dry processes for biogasification, this acitity is representing a wet process. - Air emissions from the anaerbic treatment; the composition of biogas is about 45% CO2, 54% CH4. When burned, methane also forms carbon dioxide, which is a contributor to the greenhouse effect. Overall carbon dioxide emissions from a biogasification plant is assumed to be 440 kg per tonne of wet organic material. (McDougall, 2001) Biogas also consist of chlorine H2S, HC and chlorinated HC (N2 and O2 is also possible) but these are not emitted to the air. The amount of biogas produced will depend on the nature of the organic material in the incoming waste, as well as the process used. - Water emissions from the anaerbic treatment; water is produced when the digested material is pressed or filtered. Large amount will be produced, especially in the wet process type. Some of it will be recirculated and the rest need to be treated prior to discharge. Water emissions are based on a wet two stage process producing 500 l/tonne. In this model only output of electricity is presented since production and incineration of biogas result in electricity used in the plant. Energy consumption is 50 kWh/tonne of plant input and energy production is 190 kWh/tonne of process input.(McDougall, 2001) The composition of biogas can be: CO2 45%, CH4 54%, Chlorine 0.9 mg/m3, H2S 420 mg/m3, Total HC <1.5, Chlorinated HC <1.5 (N2 and O2 is also possible). (McDougall, 2001) Mass loss due to evaporation and biodegradation of the organic fraction of final vary between 40- 80% (McDougall, 2001) Due to the wide range of different biogasification processes available mass loss vary. 60 % is a generic value used here. References: Integrated Solid Waste, F.McDougall et al, Blackscience, 2001 Bergmann and Lentz, Report, Procter and Gamble, Germany, 1992.

System Boundaries	
Nature Boundary	A biogasification plant require a considerable area of land but due to lack of data this is not included in the system. The energy consumption and the emissions to air and water are accounted for. The emissions to air and water have nature as recipient. Reported emissions are the ones measured in the study. The fact that emissions on different geographical places can have different effects on the environment has not been accounted for.
Time Boundary	Data are from studies made 1992- 2001.

Geographical Boundary	The technical system for this model is limited to a biogasification plant in Europe.
Other Boundaries	Subsystem not considered is transports from sorting station to biogasification area.
Allocations	Not applicable
Systems Expansions	Not applicable

About Inventory	
Publication	McDougall F. et al, Integrated Solid Waste Management - A Life Cycle Inventory, Procter & Gamble Technical Centres Limited, Blackwell Science, 2001 Data documented by: Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, Industrial Environmental Informatics, Chalmers University of Technology Published in SPINE@CPM: 14 August 2002
Intended User	The original study this docume
General Purpose	Data about waste management systems are insufficient and more data are required by the industry.
Detailed Purpose	This documentation is based on a study about Integrated Solid Waste Management performed by Forbes McDougall et al at Procter & Gamble Technical Centres, 2001. The aims of that study was to introduce a LCI model for Integrated Waste Mangement and to provide data that support the concept of Integrated Waste Management as a sustainable method of managing solid waste. The purpose of the documentation of this system has been to make data for waste management available in this format for the industry.
Commissioner	
Practitioner	
Reviewer	
Applicability	This set of data could be applied to a biogasification plant and it gives a rough estimation of environmental loads of the anaerobic process. For detailed study of biogasification more information is needed e.g. about the composition of the input waste, biogasification process etc. The various biogasification processes can be classified according to the solids content of the material digested, and the temperature at which the process operates. Dry anaerobic digestion may be defined as taking place at a total dry solids concentration of over 25%, below this concentration the process is described as wet digestion. To give an indication of how much biowaste usually is generated in urban areas the following example is given. A population of 500 000 with a total amount of waste generated of 230 000 tonnes, gives around 28 500 tonnes of biowaste, 4275 tonnes (15 weight-%) of non-recyclable paper and 24 225 tonnes (85 weight-%) of organic material. These figures vary between countries and areas.
About Data	Data is based on a study performed by Procter & Gambler about Integrated Waste Management (F. McDougall et al, Procter & Gamble Technical Centres Limited, Blackwell Science, 2001). Data are generally averages, giving an approximate measure of the environmental burdens

	associated with the system. The descriptions of the activity is how it was understood by the person who made the documentation. Water emissions are based on a wet two stage process producing 500 l/tonne waste treated.
Notes	For further information about solid waste managment see: Flemström K., Brief overview of solid waste management, IMI-internal report. The report may be downloaded from: http://www.imi.chalmers.se

Availability	Public

Technical System	
Name	Bore-hole based air-conditioning system. ESA-DBP
Functional Unit	Air-conditioning system which conditions and distributes a variable airflow volume (VAV) of a max. 5 m3/s
Functional Unit Explanation	Excerpt from the report, see 'Publication': ''The air-conditioning system includes the cooling and the air distribution systems. The required temperature of the supply is 15 °C all during the year, and the room temperature varies from 20 °C to 25.5 °C. The system operates for 11h (7am-18pm) each working day, 5 days a week. The lifesplan of this system as an entity is estimated to be 15 years.'' The data are valid for 1 year.
Process Type	Cradle to grave
Site	Akademiska Hus AB, Göteborg, Sweden
Sector	Goods and services for households
Owner	Akademiska Hus AB, Göteborg, Sweden
Technical system description	Schematics of the system can be found in the reference report (see 'Publication'). Excerpt from the report, see 'Publication': ''The air-conditioning system studied was installed to provide a building complex with ventilating air which should also lead off the surplus heat from the premises. Heating of the premises, provided by a separate water loop heating system, is not included in the scope of this study. (...) The gross area of the premises is 5000 m2, or 2500 m2 for each of the buildings. In each of the buildings, a new all-air, air-conditioning systems has been installed. The source of heating and cooling energy for the building complex is a bore-hole based heat pump system. (...) The system (...) consists of an air-handling unit, an air distribution system (air ducts and supply air terminal devices), and the bore-hole system which is the energy source for heating and cooling of the supply air. The heating coil in the exhaust part of the air-handling unit is used to heat supply air when required and to lead off the heat surplus from the heat pump system when it is operating it the cooling mode. Calculations of materials and energy use for the two air-conditioning systems are based on the design documents for system A (NB: bore-hole system), since both system alternatives are designed for the same building. (...) Although the disposition of the storeys differs slightly, for the estimation of the energy use, they are assumed to be similar. The total net area of the buildings is 1920 m2, which is mostly divided into cell offices and an auditorium for 150 persons. The total internal loads are assumed to be 40 W/m2, accounting for 10 W/m2 for people, and 15 W/m2 each for lighting and computerised equipment. (...) The production stage includes the assembly of the air distribution system in the building. User stage of the life cycle includes electricity for operation of the air-handling unit and the cooling system, required heat energy, and the leakage of the refrigerant. (...)

	Electricity amounts for operation of the air-handling units are estimated by using a specific fan power (SFP) factor of 1.1 kW/(m3/s) when distributing 80% of the maximum airflow, which corresponds with an SFP of 2.1 for the maximum airflow. Air is distributed in the building via a novel construction of a VAV supply air volumes at low air temperatures, 15° and lower, without a draught problem. (...) 67% of the required cooling energy is supplied by 'free' cooling energy from the bore holes; the rest is provided by the heat pump system. The bore-hole system is assumed to work in the refrigeration mode in accordance with a seasonal performance factor (SPF) of 2.5. (...) The environmental impacts of the disposal stage are calculated for material recycling (metals 95%, polyethylene 90%), for inineration with energy recovery (100% of the other plastics, 10% of polyethylene), and for land-filling (5% of all metals, 100% of the mineral wool insulation). Main assumptions made for this study are (NB: based on the comparative table): all-air; bore-hole based heat pump; variable airflow; air-conditioning system; life cycle phases: production, user, disposal; office area: 1920 m2; total airflow: 5 m3/s; supply air temperature: 15°C, exhaust air temperature 22.5 °C; internal heat loads 40 W/m3; cooling loads: 124 MWh/year; operating time: 8760 h/year, SFP: 1.1 kW/(m3/s), life span: 15 years. This process is included in the system described in: Heikkilä K. (2007). Environmental Assessment of Air-conditioning Systems. Design Considerations for Swedish Conditions. Report no. D 2007:2, Department of Building Services Engineering, Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/Heikkila_et_al_2007 Other processes in the CPM Database also included in the above publication: - Air-conditioning system. ESA-DBP - Air-and-water air conditioning system. ESA-DBP - All-air air handling unit with a cooling coil and vapour compression chiller with a refrigerant. ESA-DBP - All-air desiccant cooling air handling unit. ESA-DBP - Operation on desiccant cooling system - a technology in air conditioning. ESA-DBP - Operation on vapour compression cooling system - a technology in air conditioning. ESA-DBP

System Boundaries

Nature Boundary	In the study production, user and disposal stages are considered. The inventory analysis included parameters describing resource use and emissions to air and water.
Time Boundary	Excerpt from the report, see 'Publication': ''The technical performance of this system was monitored from May 2004 to September 2005.''
Geographical Boundary	Göteborg, Sweden
Other Boundaries	Excerpt from the report, see 'Publication': ''The environmental impact (...) is analysed by taking into account the production of materials that comprise them, the energy use for the operation of the systems, and their eventual removal. The air distribution system in the building is also included in the analysis. During the lifespan of each system, supply and exhaust air filters have to be replaced according to a predefined time schedule. As shown in earlier studies, the impact of the filter materials and their amounts (mostly sheet steel and rock wool) on the environmental performance of the whole system is negligible. Therefore, these material amounts are excluded from this analysis. Moreover, components such as silencers, dampers, various valves and screws are also excluded. Neither the transports of materials to the producers, nor to the building site, are taken into account according to the assumption that the transportation distance is equivalent for both systems and would thus not affect results.''
Allocations	Excerpt from the report, see 'Publication': ''The bore-hole system supplies two air-conditioning systems with cooling and heating energy, as well as contributing to heating of the building complex. The allocation of the environment impacts related to the bore-hole system, therefore, is made according to the following procedure. - The allocation of the component materials of the bore holes, between the heating (during the winter) and the cooling (during the summer) systems, is made according to the ratio of the design capacity required for cooling to the total (heating and cooling) design capacity. - The allocation of the component materials of the heat pump system between the two air-conditioning systems (one for Academicum and one for the renovated building) is performed according to the ratio of the maximum cooling capacities required of the first to the sum of two. - The allocation of cooling energy demand is made in accordance with the specification of the property owner that the bore-hole system supplies 2/3 of the cooling energy demand from the bore-hole storage; 1/3 is supplied by the heat pump system working in a cooling mode. - During the coldest period of the year, the heat energy demand for conditioning of the supply air is very low due to the combination of an efficient heat energy recovery and a low supply air temperature. Heat energy is supplied by the heat pump and the bore-hole system.

Intended User	LCA practitioner
General Purpose	Excerpt from the report, see 'Publication': ''An objective of this work was that it should lead to an increased knowledge of how to work with environmental issues related to air-conditioning systems for office buildings and to a greater awareness of the environmental loads related to these systems. (...) The objectives of this thesis are to: - describe how the environmental performance of air-conditioning systems can be assessed and evaluated at the design stage. The focus is on the application of existing methods for

	environmental assessment of these systems. - identify and discuss the major sources of the environmental impacts and give some general recommendations as to how to design air-conditioning systems to improve their environmental performance. - outline possible key performance indicators (KPI) for the environmental performance of the most common types of air-conditioning systems.''
Detailed Purpose	Excerpt from the report, see 'Publication': ''The purpose of this study is to evaluate the environmental impact of the bore-hole system (...) taking into account its entire life cycle. Results of this study are intended to provide both designers and decision makers with relevant information about the environmental performance of this system, and thus to enable them to identify possible modifications of the system design to improve the environmental performance of similar systems.''

Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	For more information and the comparison with the other systems see the report. The reference report is a thesis for the degree of doctor. As a part of it, seven papers are included. Paper V ''Environmental evaluation of an air-conditioning systems supplied by cooling energy from a bore-hole based heat pump system'' relates to the analysis of air-conditioning system. The function and other information was taken from the mentioned Paper V. Inventory data come from the main part of the report.

SPINE LCI dataset: Cable assembly

Administrative	
Finished	Y
Date Completed	2000-03-08
Copyright	Ericsson
Availability	Official

Technical System	
Name	Cable assembly
Functional Unit	One gram cable
Functional Unit Explanation	The motivation for choosing this functional unit is: · Suitable unit to work with in an LCA of a private branch exchanges (a complicated telecom product) · Important component of the MD110 product system and many other electronic products. The answers from component manufacturer one (CM1) and component manufacturer two (CM2) are not for the same cable. These facts are based on Ericsson technical specification of the component. DESIGN -- Component manufacturer one -- Ericsson product number: TFK 100 506/08 Ericsson description: Installation cable Conductor (Several threaded conductor of smooth heated copperwire, free from oxide

	patterns. Insulation: One layer coloured and plastizied polyvinylchloride which can be co-polymerized with vinyl acetate, thickness 0,1 mm Sheath: Conductorarea: 10 mm2 Max threaddiameter: 0,41 mm Isolation thickness: 1 mm Outer diameter: 7,6 mm -- Component manufacturer two -- Ericsson product number: TEN 250 3402/008 Ericsson description: Switchboard cable Conductor (solid, annealed, tinned copper wire, diameter 0,4 mm) Insulation: Polyamdie, PA 12, thickness 0,1 mm Sheath: Plastized PVC WITH GREY COLOUR, thickness 0,7 mm flame retardant oxygen index = 28 or greater according to ASTM D 2863 No. of pairs: 8 Overall diameter: 5,0 mm Weight: 35 kg/km
Process Type	Gate to gate
Site	Not relevant
Sector	Manufacturing
Owner	Not relevant
Technical system description	This activity includes the final assembly of cables. The activity is an average based on information acquired from two manufacturers. The description of the process is supplied by both manufacturers. The following process steps are included for manufacturer one; 1. Arrival of goods 2. PVC processing 3. Copper from conductor from reel, PVC compound from silo and Color masterbatch is put into the extruder 4. Extruder process 5. Measuring 6. Cooling 7. Electrical testing 8. Testing on reel Manufacturer one (CM1) has given some more details about the assembly. See additional information below. Manufacturer two (CM2) gave information about which process steps they had: 1. Wire drawing 2. Inspection of wire 3. Electrolytic tinning 4. Inspection of wire 5. Fine wire drawing 6. Insulation 7. Stranding 8. Sheathing 9. Inspection by quality control 10. Marking and packing but no details. Additional information: Below are some additional information supplied by each of the included component manufacturers. --Component manufacturer one -- The annual production is 60,000 meters. 1. Arrival of goods Raw material e.g. aluminium, copper, polyethylene, PVC, fillers, softeners, stabilisers etc is delivered by truck and train. 2. PVC processing PVC is processed in a compounding plant. 3. Copper from conductor from reel, PVC compound from silo and Color masterbatch are put into the extruder Aluminium and copper rods are drawn down to thinner wires and used as solid conductors or twisted together to stranded cores.

Polyethylene is delivered in bulk cargo to silo or in cartoons.

4. Extruder process

The conductors are pulled through the tools in a plastic extruder line and the plastic is formed around the conductor with tolerances according to cable construction.

This can be repeated in several steps depending on the cable construction.

All relevant testing is made on the material and on the cable during the different steps of the production in order to fulfil authority and customer as well as internal demands.

The finished cable is taken up on reels or packed in other packages according to customer needs.

The stranded copper conductor is pulled of from the wind off through the extruder where the PVC has been melted and mixed with the colour master batch.

5. Measuring

The measuring and control equipment measures the diameter of the cable and controls the line in order to keep the tolerances according to cable construction.

6. Cooling

The cable is cooled down to approximately 30º C.

7. Electrical testing

The cable runs through a electric testing equipment

8. Testing on reel

and is after that marked with an ink jet printer and taken up on a drum.

Packaging material for incoming materials is not included.
Cable package, (i.e. wooden drum), is not included.
Energy for heating of factory is not included.

Recycling can be made in two different operations.

1/ The Plastic extruder is heated up in order to get the correct viscosity on the PVC. During this start up procedure, the melted PVC is granulated in a hot melt granulater. The granules are later used as raw material in filler mixtures.

2/ During start up of an extruder line it takes some time to reach the correct dimension and quality of the cable. This scrap, which is PVC insulated copper conductor, is sent to a sub supplier, who granulate the cable scrap and separate copper from PVC.
The recycled copper is used to produce new copper.
PVC is placed in separate disposal for future use.

-- Component manufacturer two --

The annual production is 5,000,000 meters.

System Boundaries

Nature Boundary	The emissions to air have nature as recipient. Each parameter mentioned by the component manufacturers has been studied. No parameter has deliberately been disregarded when environmental impact has been studied. Included component manufacturers have not specified the same parameters. In the cases where only one manufacturer has stated a parameter this has been used. Emissions to water and soil are excluded due to lack of data.
Time Boundary	1998 The answer from the manufacturer arrived in 1998 and they measured in 1998. The process technology used is most certainly the best available as the factories are located in Sweden and the companies are well established.
Geographical Boundary	The technical system for this model is limited to the factory where the production takes place. The manufacturers included in the average are located in Sweden.
Other Boundaries	Delimitation's to the system is the final step in the making of the cable. The production of the subparts (e.g. Copper, PVC, CaCO3 and softener) of the cable is not included in this model The transportation of them to the factory is not included. For interested parties who wish to include the transport figures given from the manufacturers, can find the figures in the section Applicability. Component manufacturer one has specifically stated that the following parameters have not

	been included: - Packaging material for incoming materials is not included. - Cable package,(i.e. wooden drum), is not included. - Energy for heating of factory is not included.
Allocations	The manufacturers have not described how the allocation has been made. We did not decide or have any suggestions on how the manufacturer should allocate in their factory.
Systems Expansions	None.

Flow Data	
General Activity QMetaData	
Date Conceived	1998
Data Type	Derived, unspecified
Represents	See 'Function'
Method	The data that are presented are calculated as an average based on information from two component manufacturers. The information from the manufacturers was acquired using a LCI data questionnaire. The average for each presented flow is calculated as follows: - First the amount of each flow per functional unit is calculated for each component manufacturer - Then the calculated amount for each component manufacturer is summed for each unique flow and divided by the number of included component manufacturers In the information supplied by the manufacturer, they had indicated whether the data for each flow were measured, estimated or calculated. Below is a detailed account of the calculation procedure. Definition of variables: CMn: Component manufacturer number n. Myn: Materials, emission, waste, energy (y) given in component answer n. ACyn: Amount of material y in component, expressed in mg (or similar) by component manufacturer n Wn: Weight of one piece of component, expressed in mg (or similar) by component manufacturer n. Nyn: The flow y expressed per functional unit from manufacturer n. Step 1. For CM1 sum AC1+.+.ACn Step 2: The sum AC11+.+.ACyn = W1 Step 3: Divide all flows between M11...M1n by W1 --> N11...N1n Step 4: Repeat Step 1 to 3 for all component manufacturers and for each flow. Step 5: Sum N1n+..Nyn and divide by the number of terms for each unique flow.(material input, emission etc.) An average calculation like above of up to two answers was made.
Literature Reference	Two answers on the Ericsson products TFK 100 506/08 and TEN 250 3402/008 as well as http://www.chemfinder.com/
Notes	CM1 = component manufacturer one CM2 = component manufacturer two INFORMATION ABOUT RECYCLING CM1: Recycling can be made in two different operations. 1/ The Plastic extruder is heated up in order to get the correct viscosity on the PVC. During this start up procedure, the melted PVC is granulated in a hot melt granulater. The granules are later used as raw material in filler mixtures. 2/ During start up of an extruder line it takes some time to reach the correct dimension and quality of the cable. This scrap, which is PVC insulated copper conductor, is sent to a sub supplier, who granulate the cable scrap and separate copper from PVC. The recycled copper is used to produce new copper. PVC is placed in separate disposal for future use.

About Inventory

Publication	Not available. -- Data documented by: Anders Andrae, Ericsson Business Networks AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --

Intended User	The intended use for this LCI
General Purpose	The general purpose with this LCI model was for application in a LCA project at Ericsson Business Networks. The main goal of the study is; to compare the potential environmental impacts associated with an old (BC 8) and a new model (BC 10) of a private branch exchange (PBX) system, namely the MD110 system, and an additional objective is to include comparisons between different stages of the life cycle (e.g. manufacturing, use and end of life) of the system. The system, PBX MD110, is designed, developed and delivered by Ericsson Enterprise Systems AB. Life-Cycle Assessment methodology (following the ISO14040 standards for LCAs) will be used to determine the environmental impacts. The main purpose of the study for Ericsson is; - to learn, test and evaluate the LCA-methodology as a tool for assessing environmental improvement options in the product design process, and to make up concrete product guidelines regarding design for environment (DfE) and - to evaluate environmental aspects in new design. The relative importance for different life cycle stages may also be an important input in the internal work with an Environmental Management System for Ericsson Enterprise Systems. Another purpose of the study is; to collect and qualify data from suppliers and literature in order to build up a database for this and future LCA activities and within the project, it is also intended to analyse the possibilities to use the study as a base for future work regarding a type III ecolabeling project within Ericsson. The intended audience of the report from the project is; Ericsson's personnel: project management, system management, design, marketing and sales organisation, and thus also (in an extracted version) the Ericsson customers.
Detailed Purpose	Map a cable manufacturing/assembly process from an environmental standpoint in a structured procedure. The purpose of the project was to collect resource consumption data and emission data connected with the final assembly of cables and components in our telecom products. The usage for this set of data is life cycle assessments where cables are part of the studied system. Note: This model is one of in total eighteen models compiled at Ericsson, describing 16 component groups in the PBX. The division into component groups is based on structural resemblance, electrical function and material contents of the different components. -- Below is a list of the component groups and corresponding models that have been compiled: 1. Cables - Model: Cable assembly 2. Capacitors and filters; hole mounted devices - Model: Capacitor for hole mounting assembly 3. Capacitors; surface mounted devices - Model: Capacitor for surface mounting assembly 4. Connectors and holders - Model: Connector assembly 5. Diodes - Model: Diode wafer production and assembly 6. Display units and indicators - Model: Liquid crystal display assembly 7. Microcircuits, oscillators, quartz crystal units and delay lines (2 models) - Models: 1. Integrated circuit capsule assembly and 2. Si wafer production and Si wafer processing for integrated circuits (these models are interlinked) 8. Other - Model: ''Other'' electronic component assembly 9. Potentiometers - Model: Potentiometer assembly 10. Printed boards - Model: Printed board assembly 11. Relays - Model: Relay assembly 12. Resistor networks - Model: Resistor network assembly 13. Resistors, varistors and thermistors; hole mounted devices - Model: Resistor for hole mounting assembly 14. Resistors; surface mounted devices - Model: Resistor for surface mounting assembly

	15. Transformers and inductors - Model: Inductor assembly 16. Transistors and opto couplers (2 models) - Models: 1. Transistor assembly and 2. Si wafer production and Si wafer processing for transistors (these models are interlinked)
Commissioner	- Ericsson .

Reviewer	Pålsson, Ann-Christin - CPM Chalmers University of Technology S-412 96 Göteborg Sweden
Applicability	This set of data could be applied to cables used in electronic equipment if you know how much the cables weigh. -- Transports. -- CM1 = Component manufacturer one The calculation for all modes of transport is done like this: First the total transportation work per functional unit is calculated for each included component manufacturer. Then the total transportation is summed and divided by the number of included component manufacturers. This gives the average value for transportation by each mode of transport. -- Truck transportation: -- Component manufacturer one (CM1): Weight of component: 110.91 g PVC with weight 11.2 g is transported 450 km by road i.e. 11.2 g*450 km and Softener, DIDP 5.6 g*450 km. The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives: 7560 gkm/110.91 g = 68.16 gkm/g Component manufacturer two (CM2): Weight of component: 34.4905 g Polyamide with weight 2.946 g is transported 1250 km by road i.e. 2.946 g*1250 km, PVC 15.277 g*230 km, Polyester yarn 0.5311 g*580 and Ink 0.0113 g*640 km. 7511.48 gkm/34.4905 g = 217.78 gkm/g (CM1+CM2)/2 = 142.97 gkm/g -- Boat transportation: -- Component manufacturer one (CM1): Weight of component: 110.91 g Softener, DIDP with weight 5.6 g is transported 1000 km by boat i.e. 5.6 g*1000 km. The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives: 5600 gkm/110.91 g = 50.49 gkm/g Component manufacturer two (CM2): Weight of component: 34.4905 g Ink 0.0113 g*1200 km. 13.56 gkm/34.4905 g = 0.39 gkm/g (CM1+CM2)/2 = 25.44 gkm/g -- Train transportation: -- Component manufacturer one (CM1): Weight of component: 110.91 g Copper with weight 89 g is transported 650 km by train i.e. 89 g*450 km, PVC 11.2 g * 450 km, and CaCO3 3.4 g * 3.4 km.

	The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives: 65440 gkm/110.91 g = 590 gkm/g Component manufacturer two (CM2): Weight of component: 34.4905 g Copper rod wire with weight 19.95 g is transported 800 km by road i.e. 19.95 g*800 km and Tin 0.2627 g*800 km. 16170 gkm/34.4905 g = 468.83 gkm/g (CM1+CM2)/2 = 529.41 gkm/g
About Data	The data is based on information from two Swedish manufacturers. The information was gathered using a life cycle inventory questionnaire. All flows are not average values and where there were only one manufacturer stating a certain flow, this one was chosen in the model. Of the flows 75 % are not average values. The flows for Raw material input of Copper, Dyes and PVC are average values. In specific QMetaData for each flow, we have indicated specifically for each flow how many manufacturers have been included. The figures in the original answer from the manufacturers should all have a special tag telling if the value has been calculated, measured or estimated or a combination of two or three of them. Ericsson specifically told the manufacturers to do so. 15 % of the flows have been justestimated, 6 % have been calculated and 89 % of the flows have not been specified. The outline of the LCI data questionnaire that was used in the inventory follows below. No limitations or specifications were set for which substances they had to account -- LCI data questionnaire -- Transport description: Material type, Used weight of Material (g)/functional unit, Transport by road of Material (km), Transport by boat of Material (km), Transport by rail of Material (km). We here only asked for flows exceeded 2% by weight of the material declaration of the component. Additional information was also asked for and here some manufacturers mentioned they had aeroplane transport instead of some of the other transport modes. Process description. Description of the entire production at the plant/site and a technical description of the plant production. Description of the production line of the studied product. Flow chart of process steps for production of the studied product. Technical description of the production line. A very short description of each unit operation. Data quality. For every figure you give, give an account on how you gathered it. C = calculated, E = estimated, M = measured. General LCA-related information on the production system (Allocation procedures, system boundaries, etc.). Additional information. (E.g. planned changes in production rate) Material, components and natural resource input, etc. We told them to express data in amount per functional unit. Name of material, component or resource. Used amount (mg). Amount In Product (mg). Additional information Energy-ware input Energy -ware source. Quantity/functional unit. Unit. Energy-ware supplier, production sites (address). Suppliers of transport (address). Additional information. Emissions. Emissions to air. Indicate whether emissions from energy use are included in the data. Name of emission to air. Emission to air/functional unit (mg). Additional information. Emissions to water. Indicate if data describes emissions going to external purification plant or directly to recipient. Name of emission to water. Emission to water/functional unit (mg). Additional information. Emissions to soil.

	Name of emission to soil. Emission to soil/functional unit (mg). Additional information. Waste. Name of waste. Waste/functional unit (mg). Recycled/functional unit (mg). Additional information.

SPINE LCI dataset: Canada, electricity generation mix 1998

Administrative	
Finished	Y
Date Completed	2001-01-31
Copyright	IEA
Availability	Public

Technical System	
Name	Canada, electricity generation mix 1998
Functional Unit	Total electricity produced during 1998
Functional Unit Explanation	The electricity mix refer to the total amount of electricity generated by different power sources expressed in GWh during the year 1998.
Process Type	Unit operation
Site	Canada
Sector	Energyware
Owner	Canada
Technical system description	The generation of electricity with different power generating systems in Canada during the year 1998.

System Boundaries	
Nature Boundary	Not applicable, since the data only refer to the electricity generation mix. The environmental load for generation of electricity is not included.
Time Boundary	The data refer to 1998.
Geographical Boundary	Only electricity produced in Australia is considered. Import or export of electricity is not included.
Other Boundaries	-
Allocations	Not applicable
Systems Expansions	Not applicable

Flow Data	
General Activity QMetaData	
Date Conceived	1998
Data Type	Derived, statistics
Represents	See 'Function'
Method	The data are collected from IEA Statistics.
Literature Reference	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8, page II.300.

Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

About Inventory

Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998

	Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998

SPINE LCI dataset: Capacitor for hole mounting assembly

Administrative	
Finished	Y
Date Completed	2000-03-15
Copyright	Ericsson
Availability	Official

Technical System	
Name	Capacitor for hole mounting assembly
Functional Unit	One gram capacitor intended for hole mounting.
Functional Unit Explanation	The motivation for choosing this functional unit is: · Suitable unit to work with in an LCA of a private branch exchanges (a complicated telecom product) · Important component of the MD110 product system and many other electronic products. DESIGN The capacitor studied is a metallized plastic foil capacitor with polyester or polycarbonate dielectric material of equal size applicable to telecommunication equipment. The answers from component manufacturer one (CM1), component manufacturer two (CM2) and from the literature source are for the same component. Component manufacturer three (CM3) differs. See the specifications below. These facts are based on Ericsson technical specification of the component. --Component manufacturer one, two and literature source --

	Ericsson product number: RJA 392 26/47 Ericsson description: Capacitor Plastic foil or metallized plastic foil capacitor with polyester or polycarbonate dielectric material. Diameter: 7,5 mm Diameter terminals: 0,66 mm Height: 10 mm Width: 5 mm --Component manufacturer three -- Ericsson product number: RJE 315 2501 Ericsson description: Capacitor Polarized aluminium electrolytic capacitor. Diameter: 3.5-10.5 mm Diameter terminals: 0.3 mm Height: 4.9-10.8 mm Width: 4.1-10.5 mm
Process Type	Gate to gate
Site	Not relevant
Sector	Manufacturing
Owner	Not relevant
Technical system description	This activity includes the final assembly of a capacitor intended for hole mounting. The activity is an average based on information acquired from three manufacturers and one literature source containing two useful datasets. The description of the process is supplied by manufacturer one, but is assumed to be general for this type of manufacture. The following process steps are included; 1. Film metallization 2. Slitting 3. Winding 4. Metal spray 5. Heat treatment 6. Sawing 7. Lead welding 8. Epoxy filling 9. Quality control 10. Taping 11. Laser marking Details given about the process steps: 1. Film metallization Alu-metallization under vacuum. 2. Slitting: Slitting of the motherreels to defined reels 3. Winding: To wind mother capacitors 4. Metal spray: Metal spray is used Tto contact the film by hot aluminium and tin lead 5. Heat treatment: In the heat treatment the stabilising of the mother caps is done. 6. Sawing: Sawing to cut the capacitors with nominal value from the mother cap. 7. Lead welding: Lead welding is done to weld copper wires at the contacts. 8. Epoxy filling: Encapsulation in a polyester box with filling of epoxy. 9. Quality control: Quality gate and sampling tests. 10. Taping: Taping according to customer requirement 11. Laser marking: Marking of each capacitor.

	Additional information: Below are some additional information supplied by each of the included component manufacturers. --Component manufacturer one -- The raw materials are delivered without exeption by German suppliers, so the longest transport distance is max. about 850 km. These transports are not included in this activity. The shooping wires (see Applicability) are needed for the metal-sprayed contact layer of the capacitor and the SnPb-shooping wire will later be broken down into the elements tin and lead. Electricity is generally used for the whole production process with the exception for the shooping process, where oxygen gas and acetylene are applicated. --Component manufacturer two- The annual production is 770,000,000 pieces. The Leads Coppereld consists of Steel 67.4 %, Cu 18.9 %, Sn 13 % and Pb 0,7 %. In 1999 the production is estimated to increase to 830.000.000 pcs/year.

System Boundaries

Nature Boundary	The emissions to air and water have nature as recipient. Each parameter mentioned by the component manufacturers has been studied. No parameter has deliberately been disregarded when environmental impact has been studied. Included component manufacturers have not specified the same parameters. In the cases where only one manufacturer has stated a parameter this has been used.
Time Boundary	1998 The answer from the manufacturer arrived in 1998 and they measured in 1998. The process technology used is most certainly the best available as the factories are located in western Germany, Brasil, Japan and Sweden and the companies are well established.
Geographical Boundary	The technical system for this model is limited to the factory where the production takes place. The manufacturers included in the average are located in western Germany, Brasil, Japan and Sweden.
Other Boundaries	Delimitation's to the system is the final step in the making of the HMD capacitor. The production of the subparts (e.g. Metal plastic film, accelerator, curing agent and plastic case) of the resistor is not included in this model The transportation of them to the factory is not included. For interested parties who wish to include the transport figures given from the manufacturers, can find the figures in the section Applicability. Manufacturer two has specifically stated that these flows are not included in waste output for the model: Epoxy Resin 0,1 m3, Lubrificant Oil 0,96 m3, Solvents (Acetone) 0,12 m3, Metallized Waste (Tin) 1,4 m3, Mettalized Waste (Al) 1,17 m3 and Metal Spray with plastic 35 m3. All substances are controlled for governmental organisation and are measured in m3 All substances are deposed in waste deposit or recycled in other industries. The waste handling are not included.
Allocations	The manufacturers have not described how the allocation has been made. We did not decide or have any suggestions on how the manufacturer should allocate in their factory.
Systems Expansions	None.

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, unspecified
Represents	See 'Function'
Method	The data that is presented is calculated as an average based on information from three component manufacturers and one literature source containing two useful datasets. The information from the manufacturers was acquired using a LCI data questionnaire. The average for each presented flow is calculated as follows: - First the amount of each flow per functional unit is calculated for each component manufacturer and literature dataset - Then the calculated amount for each component manufacturer and the useful data literature dataset is summed for each unique flow and divided by the number of included component manufacturers and useful datasets from the literature. In the information supplied by the manufacturers, they had indicated whether the data for each flow were measured,

	estimated or calculated. In the literture Below is a detailed account of the calculation procedure. Definition of variables: CMn: Component manufacturer number n. Myn: Materials, emission, waste, energy (y) given in component answer n. ACyn: Amount of material y in component, expressed in mg (or similar) by component manufacturer n Wn: Weight of one piece of component, expressed in mg (or similar) by component manufacturer n. Nyn: The flow y expressed per functional unit from manufacturer n. Step 1. For CM1 sum AC1+.+.ACn Step 2: The sum AC11+.+.ACyn = W1 Step 3: Divide all flows between M11...M1n by W1 --> N11...N1n Step 4: Repeat Step 1 to 3 for all component manufacturers and for each flow. Step 5: Sum N1n+..Nyn and divide by the number of terms for each unique flow.(material input, emission etc.) An average calculation like above of up to three answers and two useful datasets from the literature was made.
Literature Reference	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8, page II.300.
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

About Inventory	
Publication	Not available. -- Data documented by: Anders Andrae, Ericsson Business Networks AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The intended use for this LCI
General Purpose	The general purpose with this LCI model was for application in a LCA project at Ericsson Business Networks. The main goal of the study is; to compare the potential environmental impacts associated with an old (BC 8) and a new model (BC 10) of a private branch exchange (PBX) system, namely the MD110 system, and an additional objective is to include comparisons between different stages of the life cycle (e.g. manufacturing, use and end of life) of the system. The system, PBX MD110, is designed, developed and delivered by Ericsson Enterprise Systems AB. Life-Cycle Assessment methodology (following the ISO14040 standards for LCAs) will be used to determine the environmental impacts. The main purpose of the study for Ericsson is; - to learn, test and evaluate the LCA-methodology as a tool for assessing environmental improvement options in the product design process, and to make up concrete product guidelines regarding design for environment (DfE) and - to evaluate environmental aspects in new design. The relative importance for different life cycle stages may also be an important input in the internal work with an Environmental Management System for Ericsson Enterprise Systems. Another purpose of the study is; to collect and qualify data from suppliers and literature in order to build up a database for this and future LCA activities and within the project, it is also intended to analyse the possibilities to use the study as a base for future work regarding a type III ecolabeling project within Ericsson. The intended audience of the report from the project is; Ericsson's personnel: project management, system management, design, marketing and sales organisation, and thus also (in an extracted version) the Ericsson customers.
Detailed Purpose	Map a capacitor manufacturing/assembly process from an environmental standpoint in a structured procedure. The purpose of the project was to collect resource consumption data and emission data connected with the final assembly of HMD capcitors and resembling components in our telecom products. The usage for this set of data is life cycle assessments where capacitors intended for hole mounting are part of the studied system. Note: This model is one of in total eighteen models compiled at Ericsson, describing 16 component groups in the PBX. The division into component groups is based on structural resemblance, electrical function and material contents of the different components. -- Below is a list of all component groups and corresponding models that have been compiled: 1. Cables - Model: Cable assembly 2. Capacitors and filters; hole mounted devices - Model: Capacitor for hole mounting assembly

	3. Capacitors; surface mounted devices - Model: Capacitor for surface mounting assembly 4. Connectors and holders - Model: Connector assembly 5. Diodes - Model: Diode wafer production and assembly 6. Display units and indicators - Model: Liquid crystal display assembly 7. Microcircuits, oscillators, quartz crystal units and delay lines (2 models) - Models: 1. Integrated circuit capsule assembly and 2. Si wafer production and Si wafer processing for integrated circuits (these models are interlinked) 8. Other - Model: ''Other'' electronic component assembly 9. Potentiometers - Model: Potentiometer assembly 10. Printed boards - Model: Printed board assembly 11. Relays - Model: Relay assembly 12. Resistor networks - Model: Resistor network assembly 13. Resistors, varistors and thermistors; hole mounted devices - Model: Resistor for hole mounting assembly 14. Resistors; surface mounted devices - Model: Resistor for surface mounting assembly 15. Transformers and inductors - Model: Inductor assembly 16. Transistors and opto couplers (2 models) - Models: 1. Transistor assembly and 2. Si wafer production and Si wafer processing for transistors (these models are interlinked)

Applicability	This set of data can be applied to capacitors intended for hole mounting in electronic equipment if you know how much the capacitors weigh. The model is also intended to be representative for small ceramic filters for hole mounting in electronic equipment. -- Transports. -- Here follows a more detailed description of transports of materials and components to the respective manufacturer factories. These transports are not included in the model. The calculation for all modes of transport is done like this: First the total transportation work per functional unit is calculated for each included component manufacturer. Then the total transportation is summed and divided by the number of included component manufacturers. This gives the average value for transportation by each mode of transport. -- Truck transportation: -- ---Component manufacturer one (CM1)--- Weight of component: 0.3132 g CM1: ((850 km)* (Al-metallized PET-film dielectric 0.03 g + Al-shooping wire 0.013 + Tin 0.056 + Lead 0.084 + Copper 0.091 + Epoxy resin 0.053 + Hardener 0.016 + PBT-case 0.057 + H2CO3 rests 0.002))/313,2 = 1090 gm/g ---Component manufacturer two (CM2)--- Weight of component: 0.3802 g CM2: Metal spraying (Al plus SnCu) 0.186 g*1100 km/0.3802 = 538 gkm/g ---Component manufacturer two (CM3)--- Weight of component: 0.187 g CM3: (Al foil 19 mg * 700 km + IIR rubber 19*500 + Separator 4*400 + Al case 46*700 + Lead wire 6*500 + Base 16*500 + Electrolyte 12*1000) / 187 mg = 425,7 gkm/g ---Literature source (CM4)--- Weight of component: 3.73259 g CM4: (Solder 2,38 g * 300 km + Epoxy resin 1,64*950 + Dielectric A 1,48*2250 + Hardener 1,07*1725 + Acetone 1*500 + Lead wire 0,36*2200 +Polypropylene 0,34*1670)/3,73259 g

(CM2+CM3+CM4+CM5)/4 = 3123 gkm/g

About Data

The data is based on information from one German, one Brasilian, one Japanese manufacturer and one literature source containing two useful datasets comparable to three manufacturers. For the manufacturers the information was gathered using a life cycle inventory questionnaire.

All flows are not average values and where there were only one manufacturer stating a certain flow, this one was chosen in the model.

Of the flows about little more than 63 % are not average values. The flows for Energy input of Electricity, Raw material input of Accelerator, Acetone, Al, Copper, Epoxy resin, Hardener, Pb, PP, Sn, Steel, Zn Emission of Hardener Waste ouput of Al, Copper, Epoxy resin, Hardener, Pb, Sn and Zn are average values.

In specific QMetaData for each flow, we have indicated specifically for each flow how many manufacturers have been included.

The figures in the original answer from the manufacturers should all have a special tag telling if the value has been calculated, measured or estimated or a combination of two or three of them. Ericsson specifically told the manufacturers to do so. The literature data did not tell if the value has been calculated, measured or estimated.

The result is that approximately 38 % of the flows used in all manufacturers answers were only calculated, 27 % were only estimated, 12 % were measured and calculated, 11 % were only measured, 7 % were a combination of calculations, measurements and estimations, 4 % were first estimated and then calculated.

All flows are not average values and where there were only one manufacturer stating a certain flow, this one was chosen in the model.

These flows were asked for and no limitations were set for which substances for which they had to account.

Transport description:
Material type, Used weight of Material (g)/functional unit, Transport by road of Material (km), Transport by boat of Material (km), Transport by rail of Material (km).

We here only asked for flows exceeded 2% by weight of the material declaration of the component.
Additional information was also asked for and here some manufacturers mentioned they had aeroplane transport instead of some of the other transport modes.´

Process description.

	Description of the entire production at the plant/site and a technical description of the plant production. Description of the production line of the studied product. Flow chart of process steps for production of the studied product. Technical description of the production line. A very short description of each unit operation. Data quality. For every figure you give, give an account on how you gatherd it. C = calculated, E = estimated, M = measured. General LCA-related information on the production system (Allocation procedures, system boundaries, etc.). Additional information. (e.g. planned changes in production rate) Material, components and natural resource input, etc. We told them to express data in amount per functional unit. Name of material, component or resource. Used amount(mg). Amount In Product(mg). Additional information Energy-ware input Energy -ware source. Quantity/functional unit. Unit. Energy-ware supplier, production site (address). Availability	Official

Technical System	
Name	Capacitor for surface mounting assembly
Functional Unit	One gram capacitor intended for surface mounting
Functional Unit Explanation	The answer from the component manufacturer (CM) is for a family of components. This family is the ceramic multilayer capacitors intended for surface mounting. Within the family the capacitors differs in size, capacitance value, tolerance, type and rated voltage. The environmental load per gram in the final assembly of the capaciors is assumed to be similar. These facts are based on Ericsson technical specification of the component. Ericsson product number: RJC 388, RJC 441 Ericsson description: Ceramic multilayer chip capacitor General information The capacitor is intended for surface mounting.

	Design Multilayer, uncapsulated ceramic chip capacitor Terminations Silver with a nickel barrier layer coated with electroplated tin och tin-lead. Dimensions: Capacitor size 1206 Weight: about 0.03 grams Length: 3.2 +/- 0.3 mm Width: 1.6 +/- 0.25 mm Height: 1.6 mm
Process Type	Gate to gate
Site	Not relevant
Sector	Manufacturing
Owner	Not relevant
Technical system description	This activity includes the final assembly of a capacitor intended for surface mounting. The activity is based on information acquired from one manufacturer. The description of the process is assumed to be general for this type of manufacture. The following process steps are included; 1. Material input 2. Formulation 3. Build-up process 4. Cutting 5. Bisquing 6. Pre-Firing 7. Firing 8. Tumbling 9. Termination 10. Flash/IR 11. Sorting 12. Outgoing Inspection 13. Taping 14. Storage Details given: 1.Material input: Incoming inspection and specific parameter check 2. Formulation: Preparation of paste, enamel and cornstarch basis including parameter check 3. Build-up process: Multilayer shift wet in wet process 4. Cutting: Cutting process + inline inspection 5. Bisquing: Organic burn-out + inspection 6. Pre-Firing: Pre-firing oven 7. Firing: Sintering process in sinter ovens, keeping specific sintering profile 8. Tumbling: The edges of the parts are rounded 9. Termination: Fixing of the termination on the chips, 3 different materials (AgPd, AgPdPt, AgNiSn) 10. Flash/IR: 100 % measurement, voltage resistance (UR) and insulation resistance (IR) 11. Sorting: 100 % automatic sorting in tolerance classes and 100 % measuring of dissipation factor 12. Outgoing Inspection: Final inspection of all electrical, mechanical and visual parameters 13. Taping: Taping in packaging units and inspection tape 14. Storage: Storage - delivery to the customer Internally 0.43 g/g of Solvents, 0,32 g/g Ceramics and 0.0064 g/g of Silver are recycled.

System Boundaries

Nature Boundary	The emissions to air have nature as recipient. Each parameter mentioned by the component manufacturers has been studied. No parameter has deliberately been disregarded when environmental impact has been studied. Emissions to water were not reported by the manufacturers.
Time Boundary	1998 The answer from the manufacturer arrived in 1998 and they measured in 1998. The process technology used is most certainly the best available as the factory is located in western Germany and the company is well established.
Geographical Boundary	The technical system for this model is limited to the factory where the production takes place. The manufacturer included in the average is located in Germany.
Other Boundaries	Delimitation's to the system is the final step in the making of the SMD capacitor. The production of the subparts (e.g. ceramic and electrodes) of the resistor is not included in this model The transportation of them to the factory is not included. For interested parties who wish to include the transport figures given from the manufacturers, can find the figures in the section Applicability.
Allocations	The manufacturers have not described how the allocation has been made.
Systems Expansions	None.

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, unspecified
Represents	See 'Function'
Method	The data that are presented are calculated based on information from one component manufacturer. The information from the manufacturer was acquired using a LCI data questionnaire. The average for each presented flow is calculated as follows: - First the amount of each flow per functional unit is calculated for each component manufacturer - Then the calculated amount for each component manufacturer is summed for each unique flow and divided by the number of included component manufacturers In the information supplied by the manufacturer, they had indicated whether the data for each flow were measured, estimated or calculated. Below is a detailed account of the calculation procedure. Definition of variables: CMn: Component manufacturer number n. Myn: Materials, emission, waste, energy (y) given in component answer n. ACyn: Amount of material y in component, expressed in mg (or similar) by component manufacturer n Wn: Weight of one piece of component, expressed in mg (or similar) by component manufacturer n. Nyn: The flow y expressed per functional unit from manufacturer n. Step 1. For CM1 sum AC1+.+.ACn Step 2: The sum AC11+.+.ACyn = W1 Step 3: Divide all flows between M11...M1n by W1 --> N11...N1n Step 4: Repeat Step 1 to 3 for all component manufacturers and for each flow. Step 5: Sum N1n+..Nyn and divide by the number of terms for each unique flow.(material input, emission etc.)
Literature Reference	One answer on the Ericsson product RJC 388, 441, chip capacitor
Notes	In the flow metadata for specific flows CM stands for component manufacturer.

About Inventory

Publication	Not available -- Data documented by: Anders Andrae, Ericsson Business Networks AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The intended use for this LCI
General Purpose	The general purpose with this LCI model was for application in a LCA project at Ericsson Business Networks. The main goal of the study is; to compare the potential environmental impacts associated with an old (BC 8) and a new model (BC 10) of a private branch exchange (PBX) system, namely the MD110 system, and an additional objective is to include comparisons between different stages of the life cycle (e.g. manufacturing, use and end of life) of the system. The system, PBX MD110, is designed, developed and delivered by Ericsson Enterprise Systems AB. Life-Cycle Assessment methodology (following the ISO14040 standards for LCAs) will be used to determine the environmental impacts.

	The main purpose of the study for Ericsson is; - to learn, test and evaluate the LCA-methodology as a tool for assessing environmental improvement options in the product design process, and to make up concrete product guidelines regarding design for environment (DfE) and - to evaluate environmental aspects in new design. The relative importance for different life cycle stages may also be an important input in the internal work with an Environmental Management System for Ericsson Enterprise Systems. Another purpose of the study is; to collect and qualify data from suppliers and literature in order to build up a database for this and future LCA activities and within the project, it is also intended to analyse the possibilities to use the study as a base for future work regarding a type III ecolabeling project within Ericsson. The intended audience of the report from the project is; Ericsson's personnel: project management, system management, design, marketing and sales organisation, and thus also (in an extracted version) the Ericsson customers.
Detailed Purpose	Map a capacitor manufacturing/assembly process from an environmental standpoint in a structured procedure. The purpose of the project was to collect resource consumption data and emission data connected with the final assembly of SMD capacitors and resembling components in our telecom products. The usage for this set of data is life cycle assessments where capacitors intended for surface mounting are part of the studied system. Note: This model is one of in total eighteen models compiled at Ericsson, describing 16 component groups in the PBX. The division into component groups is based on structural resemblance, electrical function and material contents of the different components. --- Below is a list of the component groups and corresponding models that have been compiled: 1. Cables - Model: Cable assembly 2. Capacitors and filters; hole mounted devices - Model: Capacitor for hole mounting assembly 3. Capacitors; surface mounted devices - Model: Capacitor for surface mounting assembly 4. Connectors and holders - Model: Connector assembly 5. Diodes - Model: Diode wafer production and assembly 6. Display units and indicators - Model: Liquid crystal display assembly 7. Microcircuits, oscillators, quartz crystal units and delay lines (2 models) - Models: 1. Integrated circuit capsule assembly and 2. Si wafer production and Si wafer processing for integrated circuits (these models are interlinked) 8. Other - Model: ''Other'' electronic component assembly 9. Potentiometers - Model: Potentiometer assembly 10. Printed boards - Model: Printed board assembly 11. Relays - Model: Relay assembly 12. Resistor networks - Model: Resistor network assembly 13. Resistors, varistors and thermistors; hole mounted devices - Model: Resistor for hole mounting assembly 14. Resistors; surface mounted devices - Model: Resistor for surface mounting assembly 15. Transformers and inductors - Model: Inductor assembly 16. Transistors and opto couplers (2 models) - Models: 1. Transistor assembly and 2. Si wafer production and Si wafer processing for transistors (these models are interlinked)

Reviewer	Pålsson, Ann-Christin - CPM Chalmers University of Technology S-412 96 Göteborg Sweden
Applicability	This set of data can be applied to capacitors intended for surface mounting in electronic equipment if you know how much they weigh. -- Transports. -- Here follows a more detailed description of transports of materials and components to the

	manufacturer factory. These transports are not included in the model. CM = Component manufacturer The calculation for all modes of transport is done like this: First the total transportation work per functional unit is calculated for each included component manufacturer. Then the total transportation is summed and divided by the number of included component manufacturers. This gives the average value for transportation by each mode of transport. -- Truck transportation: -- Component manufacturer (CM): Weight of component: 0.02794 g Ceramic with weight 0.033 g is transported 1000 km by road i.e. 0.033 g*1000 km, Metal paste (Ag and Pd) 0.00296 g*700 km, Nickel 0.00018 g*500 km, Tin 0.00026 g*500 km and Solvents 3.5 g*25 km. The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives: 122.792 gkm/0.02794 g = 4394.85 gkm/g
About Data	The data is based on information from one German manufacturer. The information was gathered using a life cycle inventory questionnaire. The figures in the original answer from the manufacturers should all have a special tag telling if the value has been calculated, measured or estimated or a combination of two or three of them. Ericsson specifically told the manufacturers to do so. 69 % of the flows stated by CM have been just calculated, 21 % have just been measured and 10 have only been estimated. The outline of the LCI data questionnaire that was used in the inventory follows below. No limitations or specifications were set for which substances they had to account. -- LCI data questionnaire -- Transport description: Material type, Used weight of Material (g)/functional unit, Transport by road of Material (km), Transport by boat of Material (km), Transport by rail of Material (km). We here only asked for flows exceeded 2% by weight of the material declaration of the component. Additional information was also asked for and here some manufacturers mentioned they had aeroplane transport instead of some of the other transport modes. Process description. Description of the entire production at the plant/site and a technical description of the plant production. Description of the production line of the studied product. Flow chart of process steps for production of the studied product. Technical description of the production line. A very short description of each unit operation. Data quality. For every figure you give, give an account on how you gathered it. C = calculated, E = estimated, M = measured. General LCA-related information on the production system (Allocation procedures, system boundaries, etc.). Additional information. (E.g. planned changes in production rate) Material, components and natural resource input, etc. We told them to express data in amount per functional unit. Name of material, component or resource. Used amount (mg). Amount In Product (mg). Additional information Energy-ware input Energy -ware source. Quantity/functional unit. Unit. Energy-ware supplier, production sites (address). Suppliers of transport (address). Additional information. Emissions. Emissions to air. Indicate whether emissions from energy use are included in the data. Name of emission to air. Emission to air/functional unit (mg). Additional information. Emissions to water. Indicate if data describes emissions going to external purification plant or directly to recipient. Name of emission to water. Emission to water/functional unit (mg). Additional information. Emissions to soil. Name of emission to soil. Emission to soil/functional unit (mg). Additional information.

	Waste. Name of waste. Waste/functional unit (mg). Recycled/functional unit (mg). Additional information.

SPINE LCI dataset: Cargo vessel, medium-sized (8´-2´ dwt)

Administrative	
Finished	Y
Date Completed	1998 08
Copyright	NTM
Availability	Public

Technical System	
Name	Cargo vessel, medium-sized (8´-2´ dwt)
Functional Unit	1tonkm
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 50 % for tankers, 80 % for RoRo vessles and 60% for other vessles. This is concidered representative for traffic to/from Sweden. *empty trips are included.*
Process Type	Gate to gate
Site	Sweden
Sector	Sea transport
Owner	Sweden
Technical system description	Operation of medium sized cargo vessel, 8000-2000 dwt (deadweight tonnes), with a 50% utilisation level for tank cargo and 60% for bulk cargo. Speeds around 13 knots Cargo Vessels include all vessels except RoRo vessels and ferries. Cargo Vessels thus include a large variety of different vessels; tankers, container ships, LoLo vessels, bulk vessels, vessels built for a special route etc

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO_2 -tax regulated CO_2. Diffuse emissions to air, emissions to water (e.g. discharges of oil) and emissions to ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents the fleet in 1999.
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 50 % for tankers, 80% for RoRo vessles and 60% for other vessles 60% (including empty trips) *Parameters not considered* -Driving technique -External conditions e.g. climate etc. -Maintenance level of the vessel *Excluded subsystems* -Precombustion, i.e. production and distribution of the fuel. -Maintenance of the vessel (e.g. use of anti fouling) -After-treatment of the vessel -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

Date Conceived	1998 - 09
Data Type	Derived, unspecified

Represents	NTM
Method	All vessels larger than 300 tons gross tonnage in the Swedish Shipowners' Association's register have been used as a basis for the data For each individual ship, the load capacity (in dwt), installed engine effect (in kW) (Redareföreningen 1995) and speed (in knots) have been used as a basis. The emissions have been calculated on the basis of the distribution of low and high revolution engines among the different size classes, and the emission factors of the engines (Alexandersson et al 1991), see table below. The energy use has been calculated with the assumption of an oil consumption of 200 g/kWh for both low and medium revolution engines. The emisson factors below are given in g/kWh, where kWh refer to mechanical work done by the engine. Engine type Load NOx CO CO2 THC PM Low rev 80% 17,7 0,2 600 0,8 0,9 Medium rev 80% 14 1 620 0,2 0,4 The utilisation levels used in these calculations are as follows: Tank 0,5 Bulk 0,6 RoRo 0,8 LoLo 0,6 Ferry 0,6 Others 0,6 The calculations of emissions from shipping are made according to the following principle: emission factor = spec.emission x effect x 1 x 1 speed load capacity utilisation level The *quantity value* for all parameters is an average of all vessels in the population. The *minimum value* corresponds to the individual with the lowest energy use and emissions in the population, and the *maximum value* to the individual with the largest energy use and emissions in the population.
Literature Reference	-Alexandersson, A., *Sjöfartens utsläpp av avgaser*, MariTerm, TFB-rapport 1991:18 Demker, G. et al. *Miljöeffekter av transportmedelsval för godstransporter*, MariTerm, KFB-rapport, 1994:6 *Skeppsregister 1995*, Swedish Shipowner Association Sjöbris, A., Flodström, E. *Emissions och energivärderingsprinciper för transportsystem*, MariTerm, KFB-rapport 1994:9 *Lloyds list*, 1996
Notes	Vessels are individuals, which means that the energy use and emissions for different vessels at a given size may vary greatly. The vessels are generally optimised for the shipping route on which it will operate and the cargo it will carry. Generally, smaller vessels in Swedish traffic operate shorter routes, while larger vessels are used for transports to the continent and transocean transports. Data for the individual vessel performing the transport should be used when possible. Data for Swedish flagged vessels that are members of the Swedish Shipowners´ Association may be obtained from Elisabeth Sörheim at the Swedish Shipowners´ Association.

About Inventory

Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation

Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	Sörheim, Elisabet - Swedish Shipowners Association .
Reviewer	None, to be reviewed. -
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vessel, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. Vessels are individuals, which means that the energy use and emissions for different vessels at a given size may vary greatly. The vessels are generally optimised for the shipping route on which it will operate and the cargo it will carry. Generally, smaller vessels in Swedish traffic operate shorter routes, while larger vessels are used for transports to the continent and transocean transports. Data for the individual vessel performing the transport should be used when possible. Data for Swedish flagged vessels that are members of the Swedish Shipowners´ Association may be obtained from Elisabeth Sörheim at the Swedish Shipowners´ Association or from the operators. ***Type of vessels*** *Cargo Vessles* - includes all vessels except RoRo vessels and ferries. Cargo Vessles thus include a large variety of different vessels; tankers, container ships, LoLo vessels, bulk vessels, vessels built for a special route etc. Cargo Vessles are mainly used for transportation of heavy goods over large distances. The energy use for tankers is generally lower than for other Cargo vessles. *RoRo vessels* are used for transportation of different types of load carriers such as trailers, containers etc. The cargo is rolled on the vessel. RoRo vessels generally operate at a higher speed than regular Cargo vessles. *Ferries* carry both passengers and goods. The goods are carried in trucks, trailers or trains. ***Fuel*** The fuel quality vary to a large extent between different vessels. Smaller vessels that only operate on Swedish routes generally use cleaner fuels. The main part of freighters in Swedish traffic use heavy fuel oil, with a sulphur content of 2,6 %. Small coastal freighters may however use gas oil with sulphur content of 0,1 %. Gas oil is the most refined type of fuel used in vessels (the maximum sulphur content is 1,5 %). In ferries, low sulphur fuel with sulphur content of 0,5 % is generally used. ***Reduction of emissions*** The data does not assume the use of any emission reducing measures. Different measures may be taken to reduce the emissions, e.g. water injection may reduce the emissions of NOx by 50%, and adjustments of the engine may reduce NOx emissions by 30 %. Catalytic converters may reduce NOx emissions by 90-100% and HC by 70-80%. Emissions of particles and HC are also reduced. Installation of catalytic converters is however a large investment for the shipowners. There are at present only a few vessels in Swedish traffic that has installed catalytic converters. The other measures constitute a smaller investment, and it is anticipated that the shipowners will chose these techniques to reduce emissions. ***Bulky goods*** Vessels generally handle transportation of large heavy goods over long distances. Some bulky goods are however transported by sea, primarily by RoRo vessels and ferries. The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Travelled distance*** The travelled distance of the goods may be estimated using a Nautic almanac, Lloyd. Since the utilisation level includes empty trips, no compensation in the distance for empty trips needs to be done. ***International sea transports*** When using the data for international traffic, the sulphur emissions should be adjusted, since the fuel quality may vary. Representative sulphur content of fuel used in international traffic is 3,3 %. The energy use and emissions of other parameters may also vary to a large extent depending on the quality of the fuel. The utilisation levels used in these calculations are as follows: Tank 0,5 Bulk 0,6

	RoRo 0,8 LoLo 0,6 Ferry 0,6 Others 0,6
About Data	Data have been calculated on the basis of the load capacity (in dwt), installed engine effect (in kW) (Redareföreningen) and speed (in knots) (Lloyds) of each individual ship. Emissions to air per tonkm have been calculated by using the emission factors of the engines (Alexandersson et.al. 1991), see table below, and by knowing the relation of low and medium revolution engines to different sizes of ships. The emisson factors below are given in g/kWh, where kWh refer to mechanical work done by the engine. Engine type Load NOx CO CO2 THC PM Low rev 80% 17,7 0,2 600 0,8 0,9 Medium rev 80% 14 1 620 0,2 0,4 The energy consumption has been calculated by the assumption of an oil consumption of 200g/kWh for both low and medium revolution engines. The sulphurous content of the fuel is assumed to be 2.6% for cargo-ships (Sjöbris 1994).
Notes	The person stated as ''Practitioner'' is the contact person for the data for transportation by boat in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: Cargo vessel, small (<2´dwt)

Administrative	
Finished	Y
Date Completed	1998 08
Copyright	NTM
Availability	Public

Technical System	
Name	Cargo vessel, small (<2´dwt)
Functional Unit	1 tonkm
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 50 % for tankers, 80 % for RoRo vessles and 60% for other vessles. This is concidered representative for traffic to/from Sweden. *empty trips are included.*
Process Type	Gate to gate
Site	Sweden
Sector	Sea transport
Owner	Sweden
Technical system description	Operation of small cargo vessel, including vessels smaller than 2000 dwt (deadweight tonnes), with a 50% utilisation level for tank cargo and 60% for bulk cargo. Speeds around 11 knots Cargo vessels include all vessels except RoRo vessels and ferries. Cargo Vessels thus include a large variety of different vessels; tankers, container ships,

	LoLo vessels, bulk vessels, vessels built for a special route etc.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water (e.g. discharges of oil) and emissions to ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents the fleet in 1999.
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 50 % for tankers, 80% for RoRo vessles and 60% for other vessles 60% (including empty trips) *Parameters not considered* -Driving technique -External conditions e.g. climate etc. -Maintenance level of the vessel *Excluded subsystems* -Precombustion, i.e. production and distribution of the fuel. -Maintenance of the vessel (e.g. use of anti fouling) -After-treatment of the vessel -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

RoRo vessels generally operate at a higher speed than regular Cargo vessles. *Ferries* carry both passengers and goods. The goods are carried in trucks, trailers or trains.

Fuel
The fuel quality vary to a large extent between different vessels. Smaller vessels that only operate on Swedish routes generally use cleaner fuels. The main part of freighters in Swedish traffic use heavy fuel oil, with a sulphur content of 2,6 %. Small coastal freighters may however use gas oil with sulphur content of 0,1 %. Gas oil is the most refined type of fuel used in vessels (the maximum sulphur content is 1,5 %). In ferries, low sulphur fuel with sulphur content of 0,5 % is generally used.

Reduction of emissions
The data does not assume the use of any emission reducing measures. Different measures may be taken to reduce the emissions, e.g. water injection may reduce the emissions of NOx by 50%, and adjustments of the engine may reduce NOx emissions by 30 %. Catalytic converters may reduce NOx emissions by 90-100% and HC by 70-80%. Emissions of particles and HC are also reduced. Installation of catalytic converters is however a large investment for the shipowners. There are at present only a few vessels in Swedish traffic that has installed catalytic converters. The other measures constitute a smaller investment, and it is anticipated that the shipowners will chose these techniques to reduce emissions.

Bulky goods
Vessels generally handle transportation of large heavy goods over long distances. Some bulky goods are however transported by sea, primarily by RoRo vessels and ferries. The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.

Travelled distance
The travelled distance of the goods may be estimated using a Nautic almanac, Lloyd. Since the utilisation level includes empty trips, no compensation in the distance for empty trips needs to be done.

International sea transports
When using the data for international traffic, the sulphur emissions should be adjusted, since the fuel quality may vary. Representative sulphur content of fuel used in international traffic is 3,3 %. The energy use and emissions of other parameters may also vary to a large extent depending on the quality of the fuel.

The utilisation levels used in these calculations are as follows:

Tank 0,5
Bulk 0,6
RoRo 0,8
LoLo 0,6
Ferry 0,6
Others 0,6

About Data

Data have been calculated on the basis of the load capacity (in dwt), installed engine effect (in kW) (Redareföreningen) and speed (in knots) (Lloyds) of each individual ship. Emissions to air per tonkm have been calculated by using the emission factors of the engines (Alexandersson et.al. 1991), see table below, and by knowing the relation of low and medium revolution engines to different sizes of ships.

The emisson factors below are given in g/kWh, where kWh refer to mechanical work done by the engine.
Engine type Load NOx CO CO2 THC PM
Low rev 80% 17,7 0,2 600 0,8 0,9
Medium rev 80% 14 1 620 0,2 0,4

The energy consumption has been calculated by the assumption of an oil consumption of 200g/kWh for both low and medium revolution engines.

The sulphurous content of the fuel is assumed to be 2.6% for cargo-ships (Sjöbris 1994).

The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation

Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	Sörheim, Elisabet - Swedish Shipowners Association .
Reviewer	None, to be reviewed. -
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vessel, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to get information on how the goods are handled and the transport is carried out. Vessels are individuals, which means that the energy use and emissions for different vessels at a given size may vary greatly. The vessels are generally optimised for the shipping route on which it will operate and the cargo it will carry. Generally, smaller vessels in Swedish traffic operate shorter routes, while larger vessels are used for transports to the continent and transocean transports. Data for the individual vessel performing the transport should be used when possible. Data for Swedish flagged vessels that are members of the Swedish Shipowners´ Association may be obtained from Elisabeth Sörheim at the Swedish Shipowners´ Association or from the operators. ***Type of vessels*** *Cargo Vessles* - includes all vessels except RoRo vessels and ferries. Cargo Vessles thus include a large variety of different vessels; tankers, container ships, LoLo vessels, bulk vessels, vessels built for a special route etc. Cargo Vessles are mainly used for transportation of heavy goods over large distances. The energy use for tankers is generally lower than for other Cargo vessles. *RoRo vessels* are used for transportation of different types of load carriers such as trailers, containers etc. The cargo is rolled on the vessel. RoRo vessels generally operate at a higher speed than regular Cargo vessles. *Ferries* carry both passengers and goods. The goods are carried in trucks, trailers or trains. ***Fuel*** The fuel quality vary to a large extent between different vessels. Smaller vessels that only operate on Swedish routes generally use cleaner fuels. The main part of freighters in Swedish traffic use heavy fuel oil, with a sulphur content of 2,6 %. Small coastal freighters may however use gas oil with sulphur content of 0,1 %. Gas oil is the most refined type of fuel used in vessels (the maximum sulphur content is 1,5 %). In ferries, low sulphur fuel with sulphur content of 0,5 % is generally used. ***Reduction of emissions*** The data does not assume the use of any emission reducing measures. Different measures may be taken to reduce the emissions, e.g. water injection may reduce the emissions of NOx by 50%, and adjustments of the engine may reduce NOx emissions by 30 %. Catalytic converters may reduce NOx emissions by 90-100% and HC by 70-80%. Emissions of particles and HC are also reduced. Installation of catalytic converters is however a large investment for the shipowners. There are at present only a few vessels in Swedish traffic that has installed catalytic converters. The other measures constitute a smaller investment, and it is anticipated that the shipowners will chose these techniques to reduce emissions. ***Bulky goods*** Vessels generally handle transportation of large heavy goods over long distances. Some bulky goods are however transported by sea, primarily by RoRo vessels and ferries. The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Travelled distance*** The travelled distance of the goods may be estimated using a Nautic almanac, Lloyd. Since the utilisation level includes empty trips, no compensation in the distance for empty trips needs to be done. ***International sea transports*** When using the data for international traffic, the sulphur emissions should be adjusted, since the fuel quality may vary. Representative sulphur content of fuel used in international traffic is 3,3 %. The energy use and emissions of other parameters may also vary to a large extent depending on the quality of the fuel. The utilisation levels used in these calculations are as follows: Tank 0,5 Bulk 0,6

	RoRo 0,8 LoLo 0,6 Ferry 0,6 Others 0,6
About Data	Data have been calculated on the basis of the load capacity (in dwt), installed engine effect (in kW) (Redareföreningen) and speed (in knots) (Lloyds) of each individual ship. Emissions to air per tonkm have been calculated by using the emission factors of the engines (Alexandersson et.al. 1991), see table below, and by knowing the relation of low and medium revolution engines to different sizes of ships. The emisson factors below are given in g/kWh, where kWh refer to mechanical work done by the engine. Engine type Load NOx CO CO2 THC PM Low rev 80% 17,7 0,2 600 0,8 0,9 Medium rev 80% 14 1 620 0,2 0,4 No test cycle was used to obtain the emission factors. There is however a small need for test cycles, since vessels generally operate at constant load on the engine during the sail. The fact that the engine load sometimes is lower than 80 % i.e. when sailing to and from the harbour has been neglected. This part is generally small but complicated. The calculation model may be used to calculate the energy use and emissions for a specific vessel if the loading capacity, installed engine power etc. is known. This information may be obtained from Skeppsregister. See QMetaData for details. The energy consumption has been calculated by the assumption of an oil consumption of 200g/kWh for both low and medium revolution engines. The sulphurous content of the fuel is assumed to be 2.6% for cargo-ships (Sjöbris 1994).
Notes	The person stated as ''Practitioner'' is the contact person for the data for transportation by boat in NTM. The person stated as ''Practitioner'' is the contact person for the data for transportation by boat in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: Cast iron production. ESA-DBP

Administrative	
Finished	Y
Date Completed	1996
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Cast iron production. ESA-DBP
Functional Unit	1 kg of cast iron
Functional Unit Explanation	Unknown
Process Type	Gate to gate
Site	Unknown

Sector	Manufacturing
Owner	Unknown
Technical system description	Cast iron is produced in the foundry. Excerpt from the report, see 'Publication': ''The furnace under study in this LCA is the Swan Foundry. In the foundry and electric arc furnace is used to melt together the input of pig iron, external and internal scrap. The output from the electric arc furnace is poured into a mould or a core. The pattern used is made of wood, resin or metal. For the mould making the CO2-silicate process is used. The CO2 - silicate acts like a binder in the moulding. After the process of moulding the components goes through a finishing which consists of shot-blasting, fettling and painting. The emissions from the foundry are from the electric arc furnace. The emission of particulates (...) is data from an uncontrolled furnace with a melt of alloy steel. (...) The scrap reclaimed internally by the foundry are returned to the electrical furnace and therefore not emitting any extra emissions.'' This process is included in the system described in: Thuresson J. (1996). Life Cycle Assessment of Water Pumps. Technical Environmental Planning, Report 1996:11 ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Other processes in the CPM Database also included in the above publication: - Coal mining and cleaning. ESA-DBP - Limestone quarrying. ESA-DBP - Sand extraction and processing. ESA-DBP - Sinter plant's process ESA-DBP - Uranium ore extraction and enrichment. ESA-DBP - Production of pig iron - blast furnace process. ESA-DBP

SPINE LCI dataset: Casting of iron, type V10

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Casting of iron, type V10
Functional Unit	6,59 kg cast iron
Functional Unit Explanation	6,59 kg cast iron is used to produce one bearing housing, SNL 511-609, at SKF Mekan AB in Katrineholm. Much of the data in this activity is taken from the LCA of the bearing housing SNL 511-609, and thus it was more convenient to keep their functional unit although new data also is collected. The figure 6,59 has nothing to do with guide rings as such. The guide ring will be used in the spherical roller bearing 232/530 at SKF, Göteborg.

Process Type	Unit operation
Site	SKF Mekan ABBox 89 641 21 Katrineholm
Sector	Materials and components
Owner	SKF Mekan ABBox 89 641 21 Katrineholm
Technical system description	This activity describes a process step included in the whole system activity ''Production of guide rings used for spherical roller bearings'', also available in the SPINE@CPM database. The guide ring is manufactured at SKF Mekan AB in Katrineholm and the process consists of several steps. See the activity ''Production of guide rings used for spherical roller bearings'' for details. The guide ring will finally be mounted into the SKF Spherical Roller Bearing 232/530. The function of the guide ring is to assure that the rollers stay in the raceways of the bearing. The guide ring is made of cast iron, produced mainly from scrap. After smelting of the raw materal the smelt iron is casted in a sand form. The cast iron is then further processed into guide rings. This data set describes the casting process: In the casting process the guide rings are formed into a desired shape. A sand form is used, that in this case is a Novaset sand system. The Novaset sand system consists of a forming mass that is self-stiffened: 15,65 kg sand 0,151 kg Novaset 400 0,044 kg Hardener 4030 When the form is rigid it is treated with isopropanol in order to make the surface tight. The smelt is then poured into the form and after the smelt has become hard enough, the formed is cracked. The Novaset sand is transported as non hazardous waste to a deposit. Some of the data is taken from an earlier LCA study of the bearing housing SNL 511-609: Rasmus Beckman and Henrik Olsson; Vilken miljöpåverkan uppstår vid tillverkningen av ett lagerhus?; Master Thesis at Kalmars University; August 2002.

System Boundaries

Nature Boundary	Many of the chemicals used in the process are not followed from the cradle, since it was too time consuming and the impact was assumed to be very small since the total amount was small and the substances according to product data sheets not were considered hazardous. These inflows are considered non-elementary and come from the technosphere. The Novaset sand is transported as non hazardous waste to a deposit and are thus followed to nature. Many other outflows are considered non-elementary and go to the technosphere, since it was too time consuming to follow them to the grave.
Time Boundary	The dat was collected during autumn 2002 and no changes for the procedure are planned for the nearest future.
Geographical Boundary	The casting process takes place at SKF Mekan AB in Katrineholm, Sweden.
Other Boundaries	The production of Electricity and District heat are NOT included in the dataset and must be followed from the cradle in order to obtain the total environmental impact. The sand used for the sand form should also be traced from the cradle. The activity ''Production of quartz sand'' is available in the SPINE@CPM database.
Allocations	Allocations have been made according to weight in this specific production line at SKF Mekan AB in Katrineholm
Systems Expansions	Not Applicable

Functional Unit Explanation	1 MJ input of CBG to vehicle tank
Process Type	Gate to grave
Site	
Sector	Fuel
Owner	

Technical system description	The data represent emissions from compressed biogas (CBG) combustion in heavy duty truck or bus with a spark ignition (SI) engine, Euro V, tank-to-wheel. The emission legislation uses the definition of a heavy duty vehicle having a gross weight of 3.5 tons or more. The reported emission factors should be considered as generic data, and it should be noted that the emissions for a specific vehicle and a specific mission might differ from those generic data. For example, the limit values for certification of engines have been used as basis for deriving some of the emission factors. The duty cycles used for certification are defined to cover the whole range of typical loads of an engine in different operations. The operation of a specific vehicle can however differ from the duty cycle used in the certification, resulting in different emissions than calculated with the generic emission factors. E.g. for the regulated emissions: nitrous oxides, particles, total organic compounds and carbon monoxide, the values are conservative based on the maximum emissions limits per kWh of engine output when driving at the best point (the optimal engine speed/torque operating point). In reality, the values are often lower.

Method	The emission factors (EF, kg/MJ) for the regulated emissions have been estimated based on ETC (transient test cycle for truck and bus engines), legislation limits for Euro V (2005/55/EC). The ETC cycle is for heavy duty engines and vehicle (www.dieselnet.com). Equation for calculation of emission factors for fuel use: Efficiency: 0.40 (?)= (energy work/energy in fuel) which is the efficiency at the best point (the optimal engine speed/torque operating point) and which gives the maximum emission factors within the legislation limit. EF fuel use (g/MJ)=EF work (g/kWh)/3.6*? Emissions of CO2 and SO2 have been calculated based on carbon- and sulphur content in the fuel, see documentation "Data compilation method for a specific flow" and "Reference" in the Flow table. Emissions of N2O was best estimate.
Literature Reference	Main references: (1) 2005/55/EC (2) www.dieselnet.com (3) JRC (2013) Tank-to-wheels, Report Version 4.0, JEC well -to-wheels analysis, well-to-wheels analysis of future automotive fuels and and powertrains in the European context, July 2013 (4) SS 15 54 38 (5) FordonsGas Sverige AB, Mattias Johansson, personal communication.
Notes	Vessels are individuals, which means that the energy use and emissions for different vessels at a given size may vary greatly. The vessels are generally optimised for the shipping route on which it will operate and the cargo it will carry. Generally, smaller vessels in Swedish traffic operate shorter routes, while larger vessels are used for transports to the continent and transocean transports. Data for the individual vessel performing the transport should be used when possible. Data for Swedish flagged vessels that are members of the Swedish Shipowners´ Association may be obtained from Elisabeth Sörheim at the Swedish Shipowners´ Association.

Technical system description	The data represent emissions from compressed biogas (CBG) combustion in heavy duty truck or bus with a spark ignition (SI) engine, Euro V, tank-to-wheel. The emission legislation uses the definition of a heavy duty vehicle having a gross weight of 3.5 tons or more. The reported emission factors should be considered as generic data, and it should be noted that the emissions for a specific vehicle and a specific mission might differ from those generic data. For example, the limit values for certification of engines have been used as basis for deriving some of the emission factors. The duty cycles used for certification are defined to cover the whole range of typical loads of an engine in different operations. The operation of a specific vehicle can however differ from the duty cycle used in the certification, resulting in different emissions than calculated with the generic emission factors. E.g. for the regulated emissions: nitrous oxides, particles, total organic compounds and carbon monoxide, the values are conservative based on the maximum emissions limits per kWh of engine output when driving at the best point (the optimal engine speed/torque operating point). In reality, the values are often lower.

Represents	See 'Function'
Method	The emission factors (EF, kg/MJ) for the regulated emissions have been estimated based on WHTC (World Harmonized Transient Cycle for truck and bus engines), legislation limits for Euro VI (Commission Regulation (EC) No 582/2011).The WHTC cycle is for heavy duty engines and vehicle (www.dieselnet.com). Equation for calculation of emission factors for

	fuel use: Efficiency: 0.40 (?)= (energy work/energy in fuel) which is the efficiency at the best point (the optimal engine speed/torque operating point) and which gives the maximum emission factors within the legislation limit. EF fuel use (g/MJ)=EF work (g/kWh)/3.6*? Emissions of CO2 and SO2 have been calculated based on carbon- and sulphur content in the fuel, see documentation "Data compilation method for a specific flow" and "Reference" in the Flow table. Emissions of N2O was best estimate.
Literature Reference	Main references: (1) Commission Regulation (EC) No 582/2011 (2) www.dieselnet.com (3) JRC (2013) Tank-to-wheels, Report Version 4.0, JEC well -to-wheels analysis, well-to-wheels analysis of future automotive fuels and and powertrains in the European context, July 2013 (4) SS 15 54 38 (5) FordonsGas Sverige AB, Mattias Johansson, personal communication.
Notes	Vessels are individuals, which means that the energy use and emissions for different vessels at a given size may vary greatly. The vessels are generally optimised for the shipping route on which it will operate and the cargo it will carry. Generally, smaller vessels in Swedish traffic operate shorter routes, while larger vessels are used for transports to the continent and transocean transports. Data for the individual vessel performing the transport should be used when possible. Data for Swedish flagged vessels that are members of the Swedish Shipowners´ Association may be obtained from Elisabeth Sörheim at the Swedish Shipowners´ Association.

SPINE LCI dataset: Cement production

Administrative	
Finished	Y
Date Completed	1997-05-01
Copyright	
Availability	Public

Technical System	
Name	Cement production
Functional Unit	kg
Functional Unit Explanation	1 kg cement
Process Type	Cradle to gate
Site	Cementa AB Box 33 541 21 Skövde Sweden
Sector	Materials and components
Owner	Cementa AB Box 33 541 21 Skövde Sweden
Technical system description	The production process of cement can be divided in five stages: 1. Mining of limestone 2. Grinding of limestone and other raw materials to raw meal 3. Burning of raw meal to clinker 4. Grinding of clinker to cement 5. Storage, dispatch of cement Mining of limestone The limestone is mined out from open quarries and mines. The limestone is crushed and transported to storage facilities.

	Grinding of limestone and other raw materials to raw meal The raw materials (crushed limestone, quartzite, bauxite, iron oxide, gypsum etc.) are stored in separate raw material hoppers before they are fed in to the raw meal mills. The raw meal is then transported to silos for storage and homogenisation. Depending on the specifications of the clinker and the cement, raw meal can be made in different qualities. Burning of raw meal to clinker The clinker production takes place in a rotary kiln where the temperature of the materials reaches up to 1450°C. In this process the grins are sintered together into small balls - the clinker. The clinker is cooled in air-coolers before transport to silos for storage. According to the specifications of the cement, different qualities of clinker are made. Coal and petcoke are normally used as fuel for the rotary kilns, but also other types of fossil fuel can be used. In the Nordic and some other countries, waste and hazardous waste derived fuels are used, which then replace some of the fossil fuels. Grinding of clinker to cement The clinker is ground in cement mills together with 3-7% gypsum which is added to control the setting time. Other additives such as limestone, fly ash and blastfurnace slag may be added in the grinding to modify the cement properties or to produce special qualities of cement. Storage, dispatch of cement After the grinding process the cement is conveyed to storage silos. Some cement is bagged.

System Boundaries

Nature Boundary	Emissions from the extraction and combustion of energy carriers is included. The area is not considered in this set of data. Noise is not considered. Note: Björklund interpreted the study from Stiftelsen Östfoldsforskning (STÖ) that was used as a basis for this data, that emissions from extraction and combustion of energy carriers are included. It is however not very clear, in Björklund or in the report from STÖ, that this actually is the case. See also About Data for a description of the alterations of system boundaries that has been made on the study from STÖ, to obtain the data that is presented.
Time Boundary	
Geographical Boundary	Sweden
Other Boundaries	Explosives, grind media, iron-sulfate, waste-oil and electricity are accounted for as non-elementary flows, i.e. not followed back to the cradle.

About Inventory

Publication	LCA of Builing Frame Structures Environmental Impact over the Life Cycle of Wooden and Concrete frame; Björklund, Tillman; Report 1997:2; TEP; CTH; Göteborg; Sweden -- Data documented by: Maria Erixon, project employed for the database project at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Thomas Björklund, Technical Environmental Planning, Chalmers University of Technology --
Intended User	To make an LCA of building fra
General Purpose	Among others, to analyse and assess the environmental impact of structural wooden and concrete frames in buildings during the whole life-cycle, by using the method of LCA as a tool.
Detailed Purpose	To calculate the environmental load of cement
Commissioner	- Finncement Finland .
Practitioner	Björklund Thomas, Tillman Anne-Marie - Technical Environmental Planning, CTH 412 96 Göteborg Sweden.
Reviewer	
Applicability	These data are according to Öberg M. (Cementa in Danderyd, Sweden, 1995) representative for an average Nordic cement production. Most of the cement is dispatched from the factory in bulk by ship and lorries.
About Data	The transport distance for cement from storage to customer is 160-250 km, which is not included in this set of data. The inventory data is based on an earlier study performed by Stiftelsen Östfoldforskning (STÖ). The inventory calculation in the STÖ study has however been altered to comply with the framework of this study, performed at Chalmers University of Technology (CTH). The following is a list of the alterations that has been done at CTH of inventory data from STÖ (transcript from Björklund et. al. Table 5.1) ---Type of cement production:--- CTH: only data from the production at the plant in Skövde is used STÖ: three plants in Sweden are analysed ---Energy:--- CTH: Electricity without emission factors is used STÖ: Norwegian and Swedish average energy is used CTH: The energy carrier ''Coke, mie'' is substituted with coke with no emission factors STÖ:''Coke, mie'' is the name of an energy carrier that is not available at CTH CTH: The energy carrier ''Fossil fuel'' is substituted with the use of fossil fuel without emission factor. STÖ: The energy carrier ''Fossil fuel'' is the name of an energy carrier that is not available to CTH ---Material use:--- CTH: All material use (noted in process tree by STÖ) is accounted for. These alterations in the process tree of the LCA-file give a different amount of limestone use for the production of cement STÖ: Only use of limestone is recognised ---Transports:--- CTH: Final transport from plant differs depending in where the concrete production is situated STÖ: Final transport from Skövde to Göteborg is accounted for (153 km) CTH: Diesel train transports are substituted with electricity without emission factors STÖ: Diesel train is used in some transports CTH: Train transports powered with electricity, uses electricity without emission factors STÖ: Train transports powered with electricity uses Swedish average energy CTH: Substituted with ''Road short-distance'' STÖ: The transport type ''Road transport 5 t'' is not available to CTH CTH: Substituted with ''Road long-distance'' STÖ: The transport type ''Road transport 10 t'' is not available to CTH ---Area:--- CTH: Is not considered STÖ: Is considered ---Noise:--- CTH: Is not considered STÖ: Is considered

About Inventory	
Publication	Blanco-Rosete S. R., 2002, LCA data structure and time series related to construction and maintenance in Sweden. Environmental Systems Analysis report 2002:14, Chalmers University of Technology, Gothenburg, Sweden
Intended User	LCA practitioners.
General Purpose	This process data set is recalculated to fit in the Master Thesis given in 'Publication'. Excerpt from the report (see 'Publication'): ''Construction, building maintenance and housing management contribute to a large extent to the environmental impact. When housing owners and managers perform their activities they should be aware of the environmental effects they cause. The environmental impact of existing houses could be addressed and diminished within the possibilities of a clever management.''
Detailed Purpose	Excerpt from the report (see 'Publication'): ''This master thesis descibes and defines a building system model for a multi-family house in Gothenburg over a 30 year period from 1970 to 2002 . The model was used to collect environmental impact information regarding materials or products used in the construction and maintenance of a building . The environmental impact ofa a multi-family house was evaluated through a Life Cycle Assessment (LCA). Finally to account the long sevice lifetime of a multi-family house two case studies were carried out to test if the use of Time series can illustrate the environmental impact of maintenance activities caused by decisionmaking in housing management.''
Commissioner	Not applicable - .
Practitioner	Sergio R. Blanco-Rosete - .
Reviewer	Birgit Brunklaus - Environmental Systems Analysis
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries'.
About Data	Excerpt from the report (see 'Publication'): ''The study is based on the functional unit equal to one square meter roofing during its useful life (65 years). The functional unit does not include the substructure. When the calculations for the LCI were performed the original data was modified to fit according to the functional unit of this study.'' ESA Database Project. Years: 2009-2011. Documentation completed for this data set: 2010-09-21 Administering organisation: Chalmers University of Technology, the division of Environmental Systems Analysis. Financier: The Swedish Research Council. Documentor of data: Filippa Fuhrman (ESA). Review committee for documented data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).

SPINE LCI dataset: Cleaning and blastering of cast iron

Administrative	
Finished	Y

Date Completed	02-12-31
Copyright	
Availability	Public

Technical System	
Name	Cleaning and blastering of cast iron
Functional Unit	33,75 kg cleaned and blastered cast iron
Functional Unit Explanation	33,75 kg cast iron is needed to produce one guide ring (9,604 kg)
Process Type	Unit operation
Site	SKF Mekan ABBox 89 641 21 Katrineholm
Sector	Materials and components
Owner	SKF Mekan ABBox 89 641 21 Katrineholm
Technical system description	This activity describes a process step included in the whole system activity ''Production of guide rings used for spherical roller bearings'', also available in the SPINE@CPM database. The guide ring is manufactured at SKF Mekan AB in Katrineholm and the process consists of several steps. See the activity ''Production of guide rings used for spherical roller bearings'' for details. The guide ring will finally be mounted into the SKF Spherical Roller Bearing 232/530. The function of the guide ring is to assure that the rollers stay in the raceways of the bearing. The guide ring is made of cast iron, produced mainly from scrap. After smelting of the raw materal the smelt iron is casted in a sand form. The cast iron is then further processed into guide rings. This dataset describes the cleaning and blastering of the cast iron after the casting process. ------------------ Cleaning and blastering of cast iron : When the cast iron have been cooled it is cleaned and blastered. It means that remaining material from the casting process (e.g. sand) is removed. This process is identical for bearing housing and guide rings. The casted iron components are cleaned and blastered to get rid of remaining sand and to treat the surface. This process is identical for bearing housing and guide rings produced at SKF Mekan AB in Katrineholm, and the data is obtained from an earlier LCA study: Rasmus Beckman and Henrik Olsson; Vilken miljöpåverkan uppstår vid tillverkningen av ett lagerhus?; Master Thesis at Kalmars University; August 2002.

System Boundaries	
Nature Boundary	Emissions to air and water are included. See details in the report from where the data is taken: Rasmus Beckman and Henrik Olsson; Vilken miljöpåverkan uppstår vid tillverkningen av ett lagerhus?; Master Thesis at Kalmars University; August 2002.
Time Boundary	The data was collected during autumn 2002 and no changes in the procedure are planned for the nearest future.
Geographical Boundary	The cleaning and blastering process takes place at SKF Mekan AB in Katrineholm, Sweden
Other Boundaries	The production of electricity and district heat are NOT included in this dataset and must be followed from the cradle in order to obtain the total environmental impact. See details in the report from where the data is taken: Rasmus Beckman and Henrik Olsson; Vilken miljöpåverkan uppstår vid tillverkningen av ett lagerhus?; Master Thesis at Kalmars University; August 2002.
Allocations	Allocations have been made according to weight.
Systems Expansions	Not applicable

Flow Data	
General Activity QMetaData	
Date Conceived	02-08-01 - 02-12-31
Data Type	Derived, mixed

Represents	See 'Function'.
Method	This data set is obtained from an earlier LCA study from SKF Mekan AB of Bearing Housing. All data could according to Marja Andersson at SKF Mekan AB in Katrineholm also be used for the guide ring, since the processes are the same. The data was recalculated to our specific weight (33,75 kg), since the allocations were made according to weight.

About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The data is valid for cleaning and blastering of cast iron at the specific site at SKF Mekan AB in Katrineholm, Sweden.
About Data	Data is taken from an earlier LCA study of the bearing housing SNL 511-609: Rasmus Beckman and Henrik Olsson; Vilken miljöpåverkan uppstår vid tillverkningen av ett lagerhus?; Master Thesis at Kalmars University; August 2002.
Notes	

SPINE LCI dataset: Cleaning of bearing roller

Administrative

Finished	Y
Date Completed	2002-12-12

Copyright	
Availability	

Technical System	
Name	Cleaning of bearing roller
Functional Unit	55.2 kg rollers
Functional Unit Explanation	The rollers are made of steel and weigh 9.2 kg each. There are 36 rollers in the SRB size 232/530 (see SKF General Catalogue for more info) that this dataset treats.
Process Type	Unit operation
Site	Halmstad
Sector	
Owner	Halmstad
Technical system description	This activity is a process step that is included in the process Coating of bearing rollers. The cleaning proceeds the surface coating, and both of them takes place at Balzers Sandvik Coating AB. The rollers are put in metal baskets large enough to take two SKF rollers RS-232/530 C, i e rollers for a bearing size 232/530. The cleaning process is divided into 9 steps, and the baskets are lowered in nine different baths. In the first step they are washed thoroughly to take away oil scrap from the manufacturing of rollers. Step 2 is an ultrasonic bath also containing a water-based cleaning solution. After the ultrasonic bath is a rinse bath. Step 2 and 3 is repeated three times, with softer cleaning agents for each new step. The two final steps are another two rinse baths. The wastewater from the first two steps is sent to destruction at SAKAB because it can contain oil scrap that derives from the manufacturing of the components. The wastewater from the last six steps is let out to the municipal sewage. The system starts with the inflow of freshwater, cleaning agents, energy and rollers, and it ends with the outflow of wastewater and clean rollers. For further reading about Coating of bearing rollers read Environmental Report from year 2001 Balzers Sandvik Coatings AB and Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Thechnology, December 2002.

System Boundaries	
Nature Boundary	The process has an inflow of fresh water that is a natural resource. All the other inflows come from the technosphere. All outflows leaves for the technosphere.
Time Boundary	The report from which the data is taken is published year 2001. No changes planned for the nearest future.
Geographical Boundary	This cleaning process takes place in Halmstad, Sweden.
Other Boundaries	The operation is proceeded in water and all flows are liquid flows except for the rollers. Production of electricity is not included in this dataset.
Allocations	The total amount of chemicals used during a year is divided to give an equal amount for each cleaning batch. This amount is then divided in 2 since there is room for two rollers size 232/530 in each cleaning basket. This gives the amount of used energy and chemicals for the cleaning of one roller.

Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-03-21.
Intended User	Product developer at SKF and B
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The purpose for our study is to compare a coated roller bearing to a non-coated, from cradle to grave. The coating of the rollers is preceded by a cleaning treatment.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Sandra Häggström - .
Reviewer	Olle Ramnäs -
Applicability	The dataset describes a cleaning process that is conducted in order to make substrates clean before they are coated in a PVD process. Care has to be taken to substrate size because the same amount of chemicals is used for one bath, and how many items there is room for in one bath depends on substrate size. The dataset is compiled for rollers RS-232/530 C in SKF roller bearings size 232/530 (see SKF General Catalogue for more info).
About Data	All data are gathered from a specific site, the Balzers Sandvik Coatings AB in Halmstad, Sweden. The data have been measured by the company (Balzers) and is reported in their environmental report for year 2001. The calculations are based on economical value, purchased amount of cleaning agents.

Publication	None -- Data documented by: Göran Swan, Ola Svending, STORA Corporate Research Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	LCA practitioners
General Purpose	The purpose is to supply with LCA-data for forestry to be used in further studies of wood products.
Detailed Purpose	These data are an update of earlier data on the same subject. Can also be used as an average for Sweden.
Commissioner	- Stora Corporate Research, Box 601 661 29 Säffle Sweden.
Practitioner	Swan, Göran - Stora Corporate Research, Box 601, S-661 29 Säffle, Sweden.
Reviewer	
Applicability	These data are valid for large scale clearing in forestry. It is important to check the type of fuel used. In this case, fossil fuel is assumed to be used. Other data is available from other forest companies, or from Skogforsk, or STFI. The silviculture process in Sweden has eight steps: 1. Plant nursing 2. Soil preparation 3. Planting 4. Clearing 5. Thinning 6. Fertilizing 7. Final felling 8. Forwarding This is the fourth step.

Technical System	
Name	CNG combustion in heavy duty truck or bus, spark ignition engine, Euro V, tank-to-wheel, f3 fuels
Functional Unit	1 MJ
Functional Unit Explanation	1 MJ input of CNG to vehicle tank
Process Type	Gate to grave
Site	
Sector	Fuel
Owner	
Technical system description	The data represent emissions from compressed natural gas (CNG) combustion in heavy duty truck or bus with a spark ignition (SI) engine, Euro V, tank-to-wheel. The emission legislation uses the definition of a heavy duty vehicle having a gross weight of 3.5 tons or more. The reported emission factors should be considered as generic data, and it should be noted that the emissions for a specific vehicle and a specific mission might differ from those generic data. For example, the limit values for certification of engines have been used as basis for deriving some of the emission factors. The duty cycles used for certification are defined to cover the whole range of typical loads of an engine in different operations. The operation of a specific vehicle can however differ from the duty cycle used in the certification, resulting in different emissions than calculated with the generic emission factors. E.g. for the regulated emissions: nitrous oxides, particles, total organic compounds and carbon monoxide, the values are conservative based on the maximum emissions limits per kWh of engine output when driving at the best point (the optimal engine speed/torque operating point). In reality, the values are often lower.

Data Type	
Represents	N/A
Method	The emission factors (EF, kg/MJ) for the regulated emissions have been estimated based on ETC (transient test cycle for truck and bus engines), legislation limits for Euro V (2005/55/EC). The ETC cycle is for heavy duty engines and vehicle (www.dieselnet.com). Equation for calculation of emission factors for fuel use: Efficiency: 0.40 (?)= (energy work/energy in fuel) which is the efficiency at the best point (the optimal engine speed/torque operating point) and which gives the maximum emission factors within the legislation limit. EF fuel use (g/MJ)=EF work (g/kWh)/3.6*? Emissions of CO2 and SO2 have been calculated based on carbon- and sulphur content in the fuel, see documentation "Data compilation method for a specific flow" and "Reference" in the Flow table. Emissions of N2O was best estimate.
Literature Reference	Main references: (1) 2005/55/EC (2) www.dieselnet.com (3) JRC (2013) Tank-to-wheels, Report Version 4.0, JEC well -to-wheels analysis, well-to-wheels analysis of future automotive fuels and and powertrains in the European context, July 2013 (4) Svensk fordonsgasstandard 155438 (5) The values are published by Swedegas; http://www.swedegas.se/gasnatet/gaskvalitet/gaskvalitet_i_sverige. Here an Excel file (containing measured heat values and densitites per each month) can be downloaded.
Notes	There is information about the chemicals in the specific QMetaData.

Represents	N/A
Method	The emission factors (EF, kg/MJ) for the regulated emissions have been estimated based on WHTC (World Harmonized Transient Cycle for truck and bus engines), legislation limits for Euro VI (Commission Regulation (EC) No 582/2011).The WHTC cycle is for heavy duty engines and vehicle (www.dieselnet.com). Equation for calculation of emission factors for fuel use: Efficiency: 0.40 (?)= (energy work/energy in fuel) which is the efficiency at the best point (the optimal engine speed/torque operating point) and which gives the maximum emission factors within the legislation limit. EF fuel use (g/MJ)=EF work (g/kWh)/3.6*? Emissions of CO2 and SO2 have been calculated based on carbon- and sulphur content in the fuel, see documentation "Data compilation method for a specific flow" and "Reference" in the Flow table. Emissions of N2O was best estimate.
Literature Reference	Main references: (1) Commission Regulation (EC) No 582/2011 (2) www.dieselnet.com (3) JRC (2013) Tank-to-wheels, Report Version 4.0, JEC well -to-wheels analysis, well-to-wheels analysis of future automotive fuels and and powertrains in the European context, July 2013 (4) SS 15 54 38 (5) The values are published by Swedegas; http://www.swedegas.se /gasnatet/gaskvalitet/gaskvalitet_i_sverige. Here an Excel file (containing measured heat values and densitites per each month) can be downloaded.
Notes	There is information about the chemicals in the specific QMetaData.

Flow Table and Specific Meta Data

	Input	Product	Compressed natural gas (CNG)	1			MJ	Technosphere	

Method: The emission factor applied (0.0573 kg CO2/MJ natural gas) was found in Jerksjö et al. (2010) refered to in Miljöfaktaboken 2011, Uppskattade emissionsfaktorer för bränslen, el,värme och transporter. Jerksjö, Martin. Martinsson, Fredrik (2010). Hämtning och bearbetning av data från modellen HBEFA3.1EV – The Handbook of Emission Factors for Road Transport (www.hbefa.net). The emission factor agrees well with other data sources such as PE International Gabi database. Literature:	Output	Emission	Carbon dioxide (fossil)	0.0573			kg	Air	
Method: Regulated emission calculated according to: EF fuel use (g/MJ)=EF work (g/kWh)/3.6*? Literature: Limit in Euro VI legislation	Output	Emission	Carbon monoxide	0.000444			kg	Air	
Method: Regulated emission calculated according to: EF fuel use (g/MJ)=EF work (g/kWh)/3.6*? Literature: Limit in Euro VI legislation	Output	Emission	Methane	0.0000556			kg	Air	
Method: Regulated emission calculated according to: EF fuel use (g/MJ)=EF work (g/kWh)/3.6*? Literature: Limit in Euro VI legislation	Output	Emission	Nitrogen oxides	0.0000511			kg	Air	
Method: Emissions of N2O are approximately 50 mg/kWh. This is a rough estimate based on limited data. Literature: Typical value Notes: The N2O emissions vary between different exhaust aftertreatment systems.	Output	Emission	Nitrous oxide	0.00000556			kg	Air	
Method: Regulated emission calculated according to: EF fuel use (g/MJ)=EF work (g/kWh)/3.6*? Literature: Limit in Euro VI legislation	Output	Emission	Non-methane volatile organic compounds	0.0000178			kg	Air	
Method: Regulated emission calculated according to: EF fuel use (g/MJ)=EF work (g/kWh)/3.6*? Literature: Limit in Euro VI legislation	Output	Emission	Particles (unspecified)	0.00000111			kg	Air	
Method: A conservative value since the legislation for vehicle gas based on biogas has a limit of 20 ppm sulphur in Sweden (SS 15 54 38) . 1 kg sulphur causes 2 kg SO2. There is no standard for CNG. The heat value used for calculation to SO2 from per kg fuel to per MJ fuel was 47.88 MJ/kg (Swedegas). Literature: A conservative value	Output	Emission	Sulfur dioxide	0.000000835			kg	Air	

About Inventory

Publication	Hallberg et al, (2013) "Setup of f3 data network for Well-to-wheel (method and) LCI data for fossil and renewable fuels in the Swedish market", f3 - Swedish Knowledge Centre for Renewable Transportation Fuels, f3 project report, Available at www.f3centre.se
Intended User	LCA practitioner
General Purpose	To provide and publish best available LCI data on vehicle biofuels and fossil fuels well to tank and tank to wheel relevant for the Swedish market.
Detailed Purpose	
Commissioner	- f3 - The Swedish Knowledge Centre for Renewable Transportation Fuels.
Practitioner	- Lisbeth Dahllöf (Volvo Group), Helen Mikaelsson (Scania).
Reviewer	- Lisa Hallberg, IVL
Applicability	

	About Data	This dataset is the part of the results from the f3 project "Setup of f3 data network for Well-to-wheel (Method and) LCI data for fossil and renewable fuels in the Swedish market". Further details about this project can be found in the project report.

Availability	Public

Technical System	
Name	Coal fired plant for heat and power production - Large plant
Functional Unit	1 kWh produced and delivered heat.
Functional Unit Explanation	The emissions and use of resources and raw materials are associated with the net production of 1 kWh heat.
Process Type	Gate to gate
Site	Sweden
Sector	Grid electricity and district heat
Owner	Sweden
Technical system description	BRIEF DESCRIPTION: This technical system describes the incineration process in a coal fired plant for heat and power production. The plant is located in Sweden and is fired with black coal. The heat is delivered to a district heating net. Production of materials, chemicals, electricity and transport used in association with the fuel chain and the operation and maintenance of the plant are not included. The data reported here is from 1985. There is difficulties in getting new data from combustion of coal, because it has become less profitable to use coal as fuel due to higher taxes for the energy produced. Several coal fired heat and power plants have been converted for the use of biomass fuels instead, due to lower taxes for the energy production with these fuels. The data though are typical for an older coal fired plant for heat and power production. TECHNICAL DATA FOR THE STUDIED PLANT: The data is taken from a performance test. The lenght of the performance test (hours) : 4 Total electric and thermal output (MW): 90 Total fuel use (MWh) : 323 Production of heat and electricity (MWh) : 283 Degree of thermal effieciency (%) : 87,6 PROCESS DESCRIPTION: The plant consists of a steam boiler unit of 90 MW thermal output. The dust is removed from the flue gas in an electrostatic precipitator. INCLUDED OPERATIONS: The process of the study consists of the following operations: - The feeding of the coal into the combustion process. - The combustion process. - The internal treatment of residues from the combustion process. - The removal of dust from the flue gas in the electrostatic precipitator. - The internal consumption of electricity. NOx CONTROL: No NOx control system is used in the plant. OTHER FLUE GAS CLEANING SYSTEMS: For the removal of dust from the flue gas an electrostatic precipitator is used. No sulphur control is needed, due to the low sulphur content in the fuel, 0,54 %. - In an electrostatic precipitator the dust particles are electrified and then separated from the flue gas stream by passing through an electric field with largest possible intensity.

System Boundaries	
Nature Boundary	CRITERIAS USED FOR SELECTING FLOWS: The data for reported in- and outflows are taken from the final inspection of the plant. The emission of HC is not measured.

Time Boundary	APPLICABLE TIME OF SYSTEM: This inventory was conducted using data mainly from 1985. The data consists of avarage data during four hours of performance test. This data is valid for an older coal fired plant for heat and power production.
Geographical Boundary	GEOGRAPHICAL EXTENSION (for large technical systems): This inventory has beeen conducted on a coal fired plant for heat and power production in Sweden, with swedish regulations, applicable during 1985. The collected data should only be used for swedish conditions.
Other Boundaries	NOTES OF EXCLUDED TECHNICAL SYSTEMS: The following operations have been excluded from the system: - The distribution of district heat from the plant to the consumers. - Building of the plant and the district heating net. - The cradle to gate of the internal electricity consumption. - The water consumption in the process. - The chemicals used for feedwater treatment. - The production of the stone coal. - The transportation of the fuel to the plant. - The transportation of the residues from the combusiton and cleaning process to the landfill. - The process at the landfill such as leaching, decomposition etc.
Allocations	PRINCIPLE APPLIED: In a combined power and heating plant two products of economic value are produced. For operation and maintenance of the plant the use of resources and the emissions are associated in relation to the net production of heat and power respectively. For the use of resources and the emissions that are specific for the power production are allocated to that production. Equivalent to this the use of resources and the emissions specific for the heat production are allocated to that production. Note: When both heat and power are produced the allocation between the products are the same. That is the environmental load for 1 kWh produced heat are the same as for 1 kWh produced electrical power.

About Inventory

Publication	Data documented by: Maria Münter, Birgitta Olanders at SwedPower AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Intended user of the data are
General Purpose	The general purpose of the inventory was to obtain a lifecycle inventory of heat producing plants using different types of fuels. A further purpose was to obtain data from heat producing plants with different capacities.
Detailed Purpose	The specific purpose is to compare data from plants producing heat, with various fuels, combustion technologies and flue gas cleaning systems.
Commissioner	Bodlund, Birgit - Vattenfall AB.
Practitioner	- SwedPower AB, Maria Münter, Emanuel Nandorf, Pernilla Strömberg, Andrea Wallenius, Birgitta Olanders .
Reviewer	Pålsson, Ann-Christin - CPM Technical Environmental Planning Chalmers University of Technology 412 96 Göteborg
Applicability	CERTAIN CAUTIONS: This inventory was conducted using data mainly from 1985. The data consists of average data from a performance test. This data is assumed to be valid for an older coal fired heat and power plant. There is difficulties in getting new data from combustion of coal, because it has become less profitable to use coal as fuel due to higher taxes for the energy produced from coal. Several coal fired heat and power plants have been converted for the use of biomass fuels instead, due to lower taxes for the energy production with these fuels. The data though are typical for an older coal fired plant for heat and power production. When both heat and power are produced the allocation between the products are the same.

	That is the environmental load for 1 kWh produced heat are the same as for 1 kWh produced electrical power.
About Data	Data quality in the meaning good precision for the operation of the plant concerning for example precision of emission measurements, calibration of instruments are good since the measurements have been performed by an athorized measurement firm.
Notes	Combined heat and power plants are used as base primarly during the winter half, when the need for heat and power are the largest.

Technical System	
Name	Coarse mortar production
Functional Unit	kg
Functional Unit Explanation	1 kg coarse mortar
Process Type	Gate to gate
Site	Sweden
Sector	Materials and components
Owner	Sweden
Technical system description	This system includes the production of cement, dolomite, limestone and sand. Cement, dolomite, limestone, cellulose derivative, pigments and sand is mixed at Ernström Bygg AB (Björkaverken, 710 23 Glanshammar, Sweden +46 -19 463300), the plant for mortar production. It is packaged in paper bags, 25 kilo for each mortar package or reusable 'big-packs'. Coarse mortar consist of: Binder: Lime and cement. Aggregates: Dolomite and sand. Admixtures: air entering agent and plastizicer. Portland cement Portland cement is bought from Cementa in Skövde. It is delivered in bulk, 10 tons each

time to the mortar plant in Glanshammar.

Mineral (Dolomite)
Ernströms have their own open pit mine where the dolomite is mined. The dolomite is crushed into aggregates.

Limestone (Calcium hydroxide)
Calcium hydroxide is bought from Svenska mineral in Rättvik, and is transported with heavy truck to Glanshammar (the transport is not considered in this set of data). Burnt lime is the raw material for production of calcium hydroxide. Water is added to the lime, heat is released and calcium hydroxide becomes the final product. It is represented as Limestone.

Additives (Cellulose derivative)
No data has been collected for cellulose derivative because of its small weight share compared to the total mass. The derivative is produced from betyle cellulose. No transport distance is accounted for.

Chemicals (Pigments)
No data has been collected for pigments (but use of pigment is accounted for as a non-elementary flow).

Aggregates (Sand)
The mortar plant is self providing with sand.

Admixtures
No data for the amount of used admixtures has been at hand, consequently the use is not taken into account.

Waste
Waste handling has not been accounted for, but the waste generated is deposited in the open pit mine.

System Boundaries

Nature Boundary	Waste No waste values for waste generations have been available, but the waste generated is deposited in the open pit mine.

About Inventory	
Publication	LCA of Building Frame Structures Environmental Impact over the Life Cycle of Concrete and Steel frames; Björklund T., Jönsson Å., Tillman A-M.; Report 1996:8; TEP; CTH; Göteborg; Sweden -- Data documented by: Maria Erixon, project employed for the database project at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Thomas Björklund, Technical Environmental Planning, Chalmers University of Technology --
Intended User	To make an LCA of building fra
General Purpose	Among others, to analyse and assess the environmental impact of structural wooden and concrete frames in buildings during the whole life cycle, by using the method of LCA as a tool.
Detailed Purpose	To calculate the environmental load of coarse mortar
Commissioner	- Finncement Finland .
Practitioner	Björklund Thomas, Tillman Anne-Marie - Technical Environmental Planning, CTH 412 96 Göteborg Sweden.
Reviewer	
Applicability	To calculate the total environmental load, including the cement production, you can use the data in this Database at: Name: Cement production Category: Cradle to gate Publication: LCA of Builing Frame Structures Environmental Impact over the Life Cycle of Wooden and Concrete frame; Björklund T., Tillman A-M.; Report 1997:2; Technical Environmental Planning; Chalmers University of Technology, Göteborg, Sweden
About Data	Dolomite The mine is close by the mortar plant so the transport distance is negligible. Energy use due to extraction of dolomite is integrated in the energy value. Limestone (Calcium hydroxide) No energy use due to production of calcium hydroxide is accounted for. Additives (cellulose derivative) No data has been collected for cellulose derivatives because of its small weight share compared to the total mass. Cellulose derivative is accounted for as a non-elementary flow. Chemicals (Pigments) No data is collected for pigments but use of pigment is accounted for as a non-elementary flow. Energy use Energy data for the plant in Glanshammar is given as a total for the entire plant. 45 000 tons of mortar is produced annually. Energy use amounts to 1.5 GWh of electricity annually, thus 120 MJ/ton mortar is the energy use. Electricity is accounted for as a non-elementary flow. No other products are made at the plant. The density of coarse mortar is 1500 kg/m3. Transports The cement is transported 170 km by heavy truck from Cementa to the mortar plant in Glanshammar. The limestone is transported a distance of 260 km by heavy truck, from Svenska mineral in Rättvik to Glanshammar. Further, the transport distance to the main storage is 20 km and it is done by truck. These transports are not considered in this set of data.

They are therefore calculated for a combination of several types of ships. Emission factors in g/MJ were obtained by division of the emission factors in g/tonkm by the average energy use (0,051 g/MJ). Lenner has not stated how the values were retrieved. Literature: Lenner, M. \`Energiförbrukning och avgasemission för olika transporttyper\` VTI-meddelande nr 718, Statens Väg- och Trafikinstitut, 1993 Notes:	Output	Emission	CO	0.1			g	Air	
Date concieved: 1992 Data type: Unspecified Method: The emission factor was calculated from the fuel use (0,18 g/MJ) using the carbon content in diesel. The data used in the calculation was: Heat value: 42,82 MJ/kg Density: 0,83 kg/dm3 CO2 emission: 2,61 kg CO2/dm3 fuel Literature: Lenner, M. \`Energiförbrukning och avgasemission för olika transporttyper\` VTI-meddelande nr 718, Statens Väg- och Trafikinstitut, 1993 Notes:	Output	Emission	CO2	34			g	Air	
Notes:	Output	Emission	HC	0.028			g	Air	
Date concieved: 1992 Data type: Unspecified Method: Lenner has calculated an *average emission factor* in g/tonkm, intended to represent an average value for all shipping in Sweden. They are therefore calculated for a combination of several types of ships. Emission factors in g/MJ were obtained by division of the emission factors in g/tonkm by the average energy use (0,051 g/MJ). The data was based on figures found in a document written by the Swedish Environmental Agency (Planeringsunderlag..). The emission factors in this document are given for four-stroke engines, and based on an investigation of exhaust emissions from shipping in Sweden made by Alexandersson. Data on specific emissions given in Alexandersson were mainly based on data from laboratory measurements by engine manufacturers but also measurements onboard three ships and other projects that has conducted measurements onboard sailing ships. Literature: Alexandersson, A. ''Sjöfartens utsläpp av avgaser'' TFB-meddelande nr 164, Transportforskningsdelegationen, Stockholm 1990. Lenner, M. ''Energiförbrukning och avgasemission för olika transporttyper'' VTI-meddelande nr 718, Statens Väg- och Trafikinstitut, 1993 Planeringsunderlag för samordnad investeringsplanering 1994-2003. Statens	Output	Emission	NOx	1.18			g	Air	

Naturvårdsverk 1992-04-15 Notes:									
Notes:	Output	Emission	Particles	0.05			g	Air	
Date concieved: 1991 Data type: Unspecified Method: Exhaust emission factors in g/tonkm can be read in figure 25 in Alexandersson. To obtain emission factors in g/MJ, Tillman has divided the emission factors in g/tonkm with an energy use of 0,47 MJ/tonkm Figure 25 in Alexandersson is based on total exhaust emissions and transportation by domestic shipping in Sweden 1987. It is not however clear how the background data for figure 25 were collected. Literature: Alexandersson, A. ''Sjöfartens utsläpp av avgaser'' TFB-meddelande nr 164, Transportforskningsdelegationen, Stockholm 1990.	Output	Emission	SO2	0.6			g	Air	

About Inventory	
Publication	Tillman, A-M. `Goods transportation in life cycle assessment. Standard values for energy consumption and emissions.` In: Life Cycle Assessment - Inventory Analysis Methodology: Overview, Recycling, Electricity and Transports, Swedish Waste Research Council (AFR) report nr 74, April 1995 --- Documentation and review of the report done by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	LCA practitioners
General Purpose	To fulfil a need for *standard values* to calculate energy use and exhaust emissions from goods transports.
Detailed Purpose	An update of standard values for energy use and exhaust emissions from an earlier investigation in: *Tillman, A-M., Baumann, H., Eriksson, E., Rydberg, T.* `Livscykelanalyser för förpackningsmaterial - beräkning av miljöbelastning` SOU 1991:77, Allmänna förlaget, Stockholm, 1991.
Commissioner	- .
Practitioner	Tillman, Anne-Marie - Technical Environmental Planning Chalmers University of Technology 412 96 Göteborg Sweden .
Reviewer	Pålsson, Ann-Christin - CPM Technical Environmental Planning Chalmers University of Technology 412 96 Göteborg
Applicability	*Reviewers comment:* The data should be used with great care. The energy use for different types of ships can vary depending on e. g. size, shape of the hull, hydrodynamic properties and engine strength. This can give a very broad distribution in the energy use depending on which individual ships the energy use were based.
About Data	The emissions were calculated from the energy use and emission factors. The emission factors that were used and the basis for them can be found in general metadata.
Notes	

SPINE LCI dataset: Cold reducing of steel sheets

Administrative	
Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System

Name	Cold reducing of steel sheets
Functional Unit	1 kg cold reduced steel sheet
Functional Unit Explanation	Before the steel can be coated, different pre treatments has to be done. The steel from the steel mill is first hot rolled and then pickled. After the pickling process, the steel is cold reduced and then finally coated.
Process Type	Unit operation
Site	SSAB Tunnplåt
Sector	Materials and components
Owner	SSAB Tunnplåt
Technical system description	This activity describes a process step included in the system ''Production of plywood boxes'', also available in the SPINE@CPM database. Plywood boxes are used to pack the coated and non-coated roller bearings from SKF, Göteborg, during the transportation to customers. The plywood boxes are manufactured by Nefab Emballage AB in Alfta, Sweden. The plywood box consist of plywood, steel strips, steel nails and wooden splits. The steel for the steel strips is hot rolled, pickled, cold reduced and finally coated at SSAB Tunnplåt`s line in Borlänge. This dataset describes the cold reducing of 1 kg pickled hot rolled steel sheet at SSAB Tunnplåt AB in Borlänge. This environmental profile refers to the mean values of emissions to which cold reducing lines give rise in the manufacturing of cold reduced rolled steel sheets at SSAB Tunnplåt AB in Borlänge during the years 1998-1999. All data for the process is obtained from an earlier LCA study at Nefab Emballage AB: Hillvall Maria; Transportförpackningars bidrag till reduktion av miljöbelastningen; Master Thesis at the Technical University of Luleå; 2000. The data refers to an existing EPD from SSAB Tunnplåt AB: Environmental Product Declaration from SSAB; SE 425; April 1999

System Boundaries

Nature Boundary	Emissions to air and water are included. The steel scrap from the process is reused as raw material and is thus not considered as waste, but as a co-product ending in the technosphere. For more detailed information see the EPD SE 425 from SSAB Tunnplåt AB.
Time Boundary	This environmental profile refers to the mean values of emissions to which cold reducing lines give rise in the manufacturing of cold reduced rolled steel sheets at SSAB Tunnplåt AB in Borlänge during the years 1998-1999. Changes in the process since then are not known.
Geographical Boundary	The process takes place at SSAB Tunnplåt AB in Borlänge, Sweden.
Other Boundaries	The production of electricity is NOT included in the dataset, but must be followed from the cradle in order to obtain the total environmental impact. For more detailed information see the EPD SE 425 from SSAB Tunnplåt AB.
Allocations	Allocations have been made according to weight.
Systems Expansions	Not applicable

About Inventory	
Publication	Master thesis: LCA based solution selection; Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. Both types of bearings are packed in a plywood box. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The dataset is applicable to cold reducing of steel sheets at SSAB Tunnplåt AB in Borlänge, Sweden.
About Data	All data for the process is obtained from an earlier LCA study at Nefab Emballage AB: Hillvall Maria; Transportförpackningars bidrag till reduktion av miljöbelastningen; Master Thesis at the Technical University of Luleå; 2000. The data refers to an existing EPD from SSAB Tunnplåt AB: Environmental Product Declaration from SSAB; SE 425; April 1999.

SPINE LCI dataset: Collection area driving, with diesel driven waste collection vehicle. ESA-DBP

Administrative	
Finished	Y
Date Completed	2005
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public.

Technical System	
Name	Collection area driving, with diesel driven waste collection vehicle. ESA-DBP
Functional Unit	1 h of collection area driving
Functional Unit Explanation	1 hour of collection area driving on a typical waste collection route.

Process Type	Unit operation
Site	Gothenburg, Sweden
Sector	Land transport
Owner	Gothenburg, Sweden
Technical system description	Fuel demand and emissions during collection area driving with a diesel driven waste collection vehicle. Excerpt from the report (for report see link below): ''3.3 Use of the vehicle 3.3.1 Description of a typical waste collection route In the inventory description of the use phase the waste collection route is divided into three ''sub phases'', illustrated in Figure 8. Driving the vehicle from the garage to a waste collection area, between waste collection areas, to the incineration plant and back to the garage is in this report labelled transportation. Within a waste collection area the vehicle drives short distances between sites where waste is collected. This collection area driving is separated from the transportation to and from collection areas because it is another type of driving, generally much slower and with more acceleration and braking, which leads to other exhaust emissions. At the collection stops, waste bins are collected, the waste is loaded into the vehicle and it is then compacted. A conventional vehicle keeps the engine running at the stops, idling when the workers collect waste bins and working when loading and compacting waste. In a hybrid vehicle the engine is turned off 30 seconds after it has stopped, and the electric motor is then used for loading and compacting. Sometimes the loading and compacting procedure is carried through only once at a stop and sometimes a couple of times. After having collected all waste in one collection area, it might continue to another one, located some distance away, such as another city district. When the waste container of the vehicle is full, it is taken to the incineration plant, where it is emptied. Then it might go back to the garage or to another waste collection area to continue collecting waste.'' NB: Figure 8 in the text above is figure 8 at page 22 in the report. This process is included in the system described in ''Boss A, 2005, Life cycle assessment of a gas-electric hybrid waste collection vehicle - comparison with conventional waste collection vehicles. Environmental Systems Analysis report 2005:7, Chalmers University of Technology, Gothenburg, Sweden'' at http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2005--7.pdf Other processes in the CPM Database also included in the above publication: Truck chassi manufacturing. Intended User	LCA practitioners.
General Purpose	Process data in a Master Thesis Report.
Detailed Purpose	This process data set is a part of the comparative LCA for 'Gas-Electric Hybrid Waste Collection Vehicle'.
Commissioner	Renova AB - .
Practitioner	Anna Boss - .
Reviewer	Carl Jensen, Renova AB and Karin Andersson, Chalmers -
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries'.
About Data	Excerpts from the report (for report see link in 'Publication'): ''For evaluation of a gas vehicle, measurements from the hybrid vehicle with the engine kept running at the stops were used. The values were also adjusted according to weight differences due to the extra hybrid electric equipment. The reason for not using data directly from a gas vehicle is because the gas vehicles Renova has is of an older model and have another engine type.'' ''Another important note is that the hybrid vehicle uses a catalytic converter that reduces methane emissions by 80 percent and the diesel vehicle uses a ''CRT particle filter'', which reduces emissions of particles, NOx and CO (Jensen, personal communication). The diesel vehicle fulfils the Euro 3 emission standards.'' ''Measurements were carried out during the different phases related to waste collection. While driving the vehicle at approximately constant speed, 50 km/h, transportation to and from a waste collection area was simulated. Waste collection within a collection area was simulated in a track where driving for 30 seconds followed by a 2 minutes 30 seconds stop for collection, loading and compacting. There are also measurements for idling and loading/compacting separated from the collection track. The measurements for transportation (to and from a collection area) are related to distance and the measurements for collection area driving and collection stop are related to time.'' ''To sum up, the times and distances are: Collection stop time: 1573 seconds/ton Collection area driving time: 503 seconds/ton Transportation distance, conventional vehicle: 4.67 km/ton Transportation distance, hybrid vehicle: 4.77 km/ton'' ''Emissions and resource use during electricity production were calculated using data for average Swedish electricity production (see section 3.1.2).'' NB: Section 3.1.2 is a section in the report.

	''Other energy carriers used include diesel, natural gas and fuel oil. Data about production of these were found in a study of production and use of several fuels (Uppenberg et al., 1999). Use of crude oil/natural gas as resource was not included in Uppenberg et al. Instead these resources used were assumed to be of the same amount as the fuel used (1 kg of crude oil for the use of 1 kg of fuel oil or diesel and 1 kg of natural gas for the use of 1 kg of natural gas as fuel). For a few processes, combustion of fuels (fuel oil, diesel and liquefied petroleum gas - LPG) was added using data from the energy and transport database included in LCAiT (CIT Ekologik, 2003). Also data for the production of LPG was taken from this database. Facts from Uppenberg et al. were also used to recalculate fuel amount between units of mass, volume and energy content.'' Intended User	LCA practitioners.
General Purpose	Process data in a Master Thesis Report.
Detailed Purpose	This process data set is a part of the comparative LCA for 'Gas-Electric Hybrid Waste Collection Vehicle'.
Commissioner	Renova AB - .
Practitioner	Anna Boss - .

Reviewer	Carl Jensen, Renova AB and Karin Andersson, Chalmers -
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries'.
About Data	Excerpts from the report (for report see link in 'Publication'): ''For evaluation of a gas vehicle, measurements from the hybrid vehicle with the engine kept running at the stops were used. The values were also adjusted according to weight differences due to the extra hybrid electric equipment. The reason for not using data directly from a gas vehicle is because the gas vehicles Renova has is of an older model and have another engine type.'' ''Another important note is that the hybrid vehicle uses a catalytic converter that reduces methane emissions by 80 percent and the diesel vehicle uses a ''CRT particle filter'', which reduces emissions of particles, NOx and CO (Jensen, personal communication). The diesel vehicle fulfils the Euro 3 emission standards.'' ''Measurements were carried out during the different phases related to waste collection. While driving the vehicle at approximately constant speed, 50 km/h, transportation to and from a waste collection area was simulated. Waste collection within a collection area was simulated in a track where driving for 30 seconds followed by a 2 minutes 30 seconds stop for collection, loading and compacting. There are also measurements for idling and loading/compacting separated from the collection track. The measurements for transportation (to and from a collection area) are related to distance and the measurements for collection area driving and collection stop are related to time.'' ''To sum up, the times and distances are: Collection stop time: 1573 seconds/ton Collection area driving time: 503 seconds/ton Transportation distance, conventional vehicle: 4.67 km/ton Transportation distance, hybrid vehicle: 4.77 km/ton'' ''Emissions and resource use during electricity production were calculated using data for average Swedish electricity production (see section 3.1.2).'' NB: Section 3.1.2 is a section in the report. ''Other energy carriers used include diesel, natural gas and fuel oil. Data about production of these were found in a study of production and use of several fuels (Uppenberg et al., 1999). Use of crude oil/natural gas as resource was not included in Uppenberg et al. Instead these resources used were assumed to be of the same amount as the fuel used (1 kg of crude oil for the use of 1 kg of fuel oil or diesel and 1 kg of natural gas for the use of 1 kg of natural gas as fuel). For a few processes, combustion of fuels (fuel oil, diesel and liquefied petroleum gas - LPG) was added using data from the energy and transport database included in LCAiT (CIT Ekologik, 2003). Also data for the production of LPG was taken from this database. Facts from Uppenberg et al. were also used to recalculate fuel amount between units of mass, volume and energy content.'' NB: Complete references to Uppenberg et al. (1999) and CIT Ekologik (2003) can be found in the report. ____ ESA Database Project. Years: 2009-2011. Technical System	
Name	Collection stop, with diesel driven waste collection vehicle. ESA-DBP
Functional Unit	1 h of collection stop
Functional Unit Explanation	1 hour of collection stop (idling and working) on a typical waste collection route.
Process Type	Unit operation
Site	Gothenburg, Sweden
Sector	Land transport
Owner	Gothenburg, Sweden
Technical system description	Fuel demand and emissions during collection stop with a diesel driven waste collection vehicle. Excerpt from the report (for report see link below): ''3.3 Use of the vehicle 3.3.1 Description of a typical waste collection route In the inventory description of the use phase the waste collection route is divided into three ''sub phases'', illustrated in Figure 8. Driving the vehicle from the garage to a waste collection area, between waste collection areas, to the incineration plant and back to the garage is in this report labelled transportation. Within a waste collection area the vehicle drives short distances between sites where waste is collected. This collection area driving is separated from the transportation to and from collection areas because it is another type of driving, generally much slower and with more acceleration and braking, which leads to other exhaust emissions. At the collection stops, waste bins are collected, the waste is loaded into the vehicle and it is then compacted. A conventional vehicle keeps the engine running at the stops, idling when the workers collect waste bins and working when loading and compacting waste. In a hybrid vehicle the engine is turned off 30 seconds after it has stopped, and the electric motor is then used for loading and compacting. Sometimes the loading and compacting procedure is carried through only once at a stop and sometimes a couple of times. After having collected all waste in one collection area, it might continue to another one, located some distance away, such as another city district. When the waste container of the vehicle is full, it is taken to the incineration plant, where it is emptied. Then it might go back to the garage or to another waste collection area to continue collecting waste.'' NB: Figure 8 in the text above is figure 8 at page 22 in the report. This process is included in the system described in ''Boss A, 2005, Life cycle assessment of a gas-electric hybrid waste collection vehicle - comparison with conventional waste collection vehicles. There are also measurements for idling and loading/compacting separated from the collection track. The measurements for transportation (to and from a collection area) are related to distance and the measurements for collection area driving and collection stop are related to time.'' ''To sum up, the times and distances are: Collection stop time: 1573 seconds/ton Collection area driving time: 503 seconds/ton Transportation distance, conventional vehicle: 4.67 km/ton Transportation distance, hybrid vehicle: 4.77 km/ton'' ''Emissions and resource use during electricity production were calculated using data for average Swedish electricity production (see section 3.1.2).'' NB: Section 3.1.2 is a section in the report. ''Other energy carriers used include diesel, natural gas and fuel oil. Data about production of these were found in a study of production and use of several fuels (Uppenberg et al., 1999). Use of crude oil/natural gas as resource was not included in Uppenberg et al. Instead these resources used were assumed to be of the same amount as the fuel used (1 kg of crude oil for the use of 1 kg of fuel oil or diesel and 1 kg of natural gas for the use of 1 kg of natural gas as fuel). For a few processes, combustion of fuels (fuel oil, diesel and liquefied petroleum gas - LPG) was added using data from the energy and transport database included in LCAiT (CIT Ekologik, 2003). Also data for the production of LPG was taken from this database. Facts from Uppenberg et al. were also used to recalculate fuel amount between units of mass, volume and energy content.'' NB: Complete references to Uppenberg et al. (1999) and CIT Ekologik (2003) can be found in the report. ____ ESA Database Project. Years: 2009-2011. Administering organisation: Chalmers University of Technology, the department of Environmental Systems Analysis. Financier: The Swedish Research Council. Documentor of data: Filippa Fuhrman (ESA), assisted by Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).

Availability	Public

Technical System	
Name	Combined heat and power plant (CFB-KVV) with support systems
Functional Unit	Net production of 1 kWh electricity
Functional Unit Explanation	The emissions and use of resources and raw materials are associated with the production of 1 kWh electricity.
Process Type	Cradle to gate
Site	
Sector	Grid electricity and district heat
Owner	
Technical system description	The studied system include *fuel production, operation and maintenance and handling of rest products of a combined heat and power plant with conventional steam cycle with a circulating fluidisation bed, equipped with flue gas condensing equipment (CFB-KVV)*. Production of materials, chemicals and electricity and transports, used in association with the fuel chain and the operation and maintenance of the plant are included. *The fuel is 100% fuel wood.* Fuel wood consists of splintered (flisade) felling rests such as branches and twigs from final cutting and small trees from thinning. Wood fuel is taken out as a by-product at final cutting, approximately every 80 years in the middle of Sweden. The fuel can also be extracted at thinning and clearing work. The fuel chain include collection and splintering (flisning) of felling rests, fuel transport and combustion and restoration of the ashes to the forest or field or to final waste. *Technical data* for the studied plant: Annual time of use (hours): 4400 Supplied fuel effect (MW): 33 Heat effect, net (MW): 21+6 where 6 MW refer to heat from flue gas condensation. Electric effect, net (MW): 9 Normal annual electricity production (GWh): 40 Assumed life-time (years): 40 Electricity production, net during 40 years (TWh): 1,6

System Boundaries	
Nature Boundary	In this study, fuel wood are used. The analysis starts at the *collection and splintering of felling rests.* The environmental influence of activities before collection and splintering (flisning) of felling rests, i.e. felling are excluded and has been allocated to the production of saw timber and pulp wood, since this takes place independent on the extraction of fuel. All emissions are considered equivalent, independent of where they take place (locally,

	regionally, globally; in densely populated areas or rural areas).
Time Boundary	The combined heat and power plant is assumed to have an operation time of 40 years.
Geographical Boundary	Sweden
Other Boundaries	The studied system include *fuel production, operation and maintenance and handling of rest products of a combined heat and power plant with conventional steam cycle with a circulating fluidisation bed, equipped with flue gas condensing equipment.* Calculations of building and demolition of the plant has been performed but are not included in this system. ***Sub-systems included in the system:*** • Collection and splintering of felling rests, fuel transport and combustion and restoration of the ashes to the forest or field or to final waste. • Use of resources and emissions associated with reinvestments and reconstruction. Concrete constructions and buildings are however not considered to need renewal during the lifetime of the power station. • Use of resources and emissions to air from production of the electricity that is used in the life cycles. • Energy use and emissions for the production of oil for the studied manufacturing processes and transports. • Known use of chemicals are accounted for. In the cases where it was possible to obtain data, resource use and emissions for the production are included. ***Sub-systems excluded from the system:*** • The part of fuel production, operation and rest products handling that can be assigned to heat production. The allocation principles are described under Allocation. • Equipment after the power station transformer. • The risk of major accidents and rare breakdowns and environmental consequences from these. • Work environment. • Environmental loads caused by the operation personnel. • Waste and rest products are transported to final waste. Operation and chemical and biological decomposing processes (nedbrytningsprocesser) in the final waste have not been considered.
Allocations	The *50/50 method* has been applied throughout the calculations. The method is described in ''Nordic Guidelines on Life-Cycle Assessment'', Nord 1995:20, The Nordic Council, Stockholm. For the combined heat and power plant, the production and transport of fuel, emissions from operation, use of chemicals at operation of the plant are *allocated in proportion to the production of heat and power (in kWh).* For operation and maintenance, including replacement of materials, the use of resources and emissions for components that are specific for the electricity production are allocated to the electricity production.

About Inventory

Publication	Brännström-Norberg B-M., Dethlefsen U., Johansson R., Setterwall C., Tunbrant S.,''Livscykelanalys för Vattenfalls elproduktion - Sammanfattande rapport'', Vattenfall AB Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology
Intended User	The data can be used as a basi
General Purpose	• The work with life-cycle analysis are expected to *contribute to a reinforcement and structuring* of the environmental work within Vattenfall, and a deeper knowledge on

	the use of resources and emissions to the environment. • An LCA can *facilitate a need for reliable data for electricity production.* Electricity is used in the manufacture of almost every product, and data from an LCA can be used when conducting an LCA on products. • An LCA can *facilitate a choice between different techniques* for future electricity production. • An LCA can also help to *choose the most effective alternatives* to reduce the consumption of resources and environmental influence of the current electricity production system. • It is also possible to *compare* the environmental load for different alternatives of electricity production.
Detailed Purpose	To obtain a *reliable basis* to be able to perform life-cycle analyses of different types of electricity use, and to identify opportunities for improvements in the existing system. To identify data gaps and areas where the knowledge are poor.
Commissioner	- Vattenfall Elproduktion .
Practitioner	- Vattenfall Energisystem AB: Britt-Marie Brännström-Norberg Ulrika Dethlefsen Roland Johansson Caroline Setterwall Sofie Tunbrant .
Reviewer	- Thomas Ekvall, Chalmers Industriteknik (CIT) Gunnar Lindfors, Institutet för Vatten- och Luftvårdsforskning (IVL) Göran Finnveden, Institutet för Vatten- och Luftvårdsforskning (IVL)
Applicability	The studied system include fuel production, operation and maintenance and handling of rest products of a combined heat and power plant with conventional steam cycle with a circulating fluidisation bed, equipped with flue gas condensing equipment (CFB-KVV). The fuel chain and combustion of fuel wood in a CFB-boiler should be *applicable on current bio-fired plants.* The calculations concern the *electricity production*. The use of resources and emissions from heat production can be calculated from these data. Combined heat and power are primarily used during the winter half, when the need for both heat and power are the largest. Transmission and distribution losses are not included. When the result is used to study different types of electricity use, these losses should be included. A rough estimate are that the distribution losses for a large industry customer are approximately 5% of the bought electricity, i.e. to obtain data for the use of electricity the data should be multiplied with 1,05. For an average household customer the transmission losses are approximately 10% of the bought electricity, i.e. the data should be multiplied with 1,10. The CFB-boiler are throughout the calculations assumed to be *equipped with flue gas condensing equipment.* If the results are applied to existing combined heat and power plants, the use of resources and emissions per produced kWh electricity will be higher, since a plant without flue gas condensing equipment have a lower total degree of efficiency. The fuel in this study is *100% fuel wood.* Fuel wood consists of splintered felling rests such as branches and twigs from final cutting and small trees from thinning. Wood fuel is taken out as a by-product at final cutting, approximately every 80 years in the middle of Sweden. The fuel can also be extracted at thinning and clearing work. Calculations for 100% salix (energy forest) fuel have been performed but are not reported. The *emission regulations* that are applied for the specific plant have a major influence on the emissions of NOx, N2O, NH3 and SO2. Fairly strict emission regulations have been chosen. The specific material use for a certain combustion technique and fuel are independent of where the plant is located. Other parameters can however vary, e.g. the transport distances. Data on the fuel use of *felling machinery and tractors* were collected a few years ago. The values are representative for the machines used today. New machines with better performance are being developed. The use of "old" data may give an overestimation of the calculated emissions from fuel production. The complete study include building, operation and maintenance, and demolition of the power plant and fuel production and handling of rest products from the fuel. When the

	data is used for energy production in a life cycle analysis of a product or a system, that do not require expansion of the electricity production system, it however reasonable only to include fuel production, operation and maintenance and handling of rest products from the fuel. The other phases of the life cycle are the same independent on the electricity production.
About Data	The plant studied, are a combined heat and power plant with a conventional steam cycle with a circulating fluidisation bed, equipped with flue gas condensing equipment (CFB-KVV). The fuel type and fuel handling are similar for a combined heat and power plant with a pressurised carburation combination cycle. The amount of supplied fuel and degree of efficiency however, varies. Data has been obtained from *existing plants* belonging to Vattenfall. The fuel is 100% fuel wood. Relevant data for transports, extraction and production of metals and chemicals, and manufacture and work on important components were hard to obtain. Data from manufacturers and other reports and studies, primarily life cycle analyses have been used. Production of material and transports are considered with current technology. Swedish standard values have been used to calculate fuel use and emissions from transports. Transport distances are specific for the operation of the plant. *The parameters that are presented* are chosen because they have a general interest and because the basis for these parameters are relatively good. All values are reported with 3 figures. The data are however seldom that accurate. Data on the fuel use of felling machinery and tractors were collected a few years ago but are representative for the machines used today. Use of resources and emissions associated with *reinvestments and reconstruction are included*. They are generally assumed to give an addition of 1 % per year of the use of resources and emissions at the building phase. Concrete constructions and buildings are however not considered to need renewal during the lifetime of the power station. The following data has been used in the analysis (tonnes per year during 40 years) Steel: 1,70 Copper: 0,01 Brick: 0,10 Ammonia: 0,23 "Cyclohexylamin" 0,015 Hydrazine: 0,075 Sodium chloride: 0,25 The following *emission factors* have been used to calculate emissions from the operation of the plant. The emission factors are based on data from existing plants. NOx: 55 mg/MJ used fuel, 1,8e-1 g/kWh electricity SO2: 10 mg/MJ used fuel, 1,28e-1 g/kWh electricity CO: 50 mg/MJ used fuel, 1,60e-1 g/kWh electricity Particles: 5 mg/MJ used fuel, 1,60e-1 g/kWh electricity NH3: - mg/MJ used fuel, - g/kWh electricity N2O: 5 mg/MJ used fuel, 1,60e-2 g/kWh electricity CO2: 100000 mg/MJ used fuel, 3,30e2 g/kWh electricity For electricity used in the manufacture of materials and fuels, *average electricity* for the respective countries distributed on the different electricity production alternatives have been used. The following *degrees of efficiencies* have been used to calculate the fuel used in the electricity production. The values are standard values for existing power plants. New modern plants often have higher degrees of efficiencies. The values are calculated from the effective heat value in the used fuels and the energy content in the steam produced in a nuclear power plant. • Coal condensing: 40% • Oil condensing: 40% • Natural gas condensing/combination: 40% • Gas turbine: 25% • Combined heat and power plant(irrespective of fuel) 30% (for electricity production) 85% (total for electricity and heat production)

	• Water power: are not recalculated, are accounted for as kWh electricity • Nuclear power: 33%, are however not recalculated, but accounted for as kWh electricity or gram natural uranium.
Notes	When wood is extracted, nutritious substances, nitrogen and minerals are extracted at the same time. They would otherwise have been supplied to the forest when the tree dies and are decomposed. The content of nutritious substances are higher in branches and treetops than in the trunk wood. Extraction of felling rests influences the mineral balance negatively. The return of ashes are therefore considered to be a condition for an extensive use of wood fuel. Extraction of nitrogen in combination with return of nutritious substances, e.g. in association with ashes are estimated to give an relief to nitrogen rich forest systems and are estimated to bring about an increased resistance against acidification. Final cutting has a large influence on the landscape through clear-cut forests. The extraction of wood fuel then often has a positive effect on the landscape. Combined heat and power are used as base primarily during the winter half, when the need for both heat and power are the largest.

The other phases of the life cycle are the same independent on the electricity production.

About Data

The plant studied is a combined heat and power plant with a pressurised carburation and combination cycle (GCC-KVV). The plant has a higher degree of efficiency than conventional bio-fired plants. Data has been obtained from one of Vattenfall:s prospected plants. The fuel is 100% fuel wood.

Relevant data for transports, extraction and production of metals and chemicals, and manufacture and work on important components were hard to obtain. Data from manufacturers and other reports and studies, primarily life cycle analyses have been used. Production of material and transports are considered with current technology. Swedish standard values have been used to calculate fuel use and emissions from transports. Transport distances are specific for the operation of the plant.

The parameters that are presented are chosen because they have a general interest and because the basis for these parameters are relatively good. All values are reported with 3 figures. The data are however seldom that accurate.

Data on the fuel use of felling machinery and tractors were collected a few years ago but are representative for the machines used today.

Use of resources and emissions associated with *reinvestments and reconstruction are included*. They are generally assumed to give an addition of 1 % per year of the use of resources and emissions at the building phase. Concrete constructions and buildings are however not considered to need renewal during the lifetime of the power station. The following data has been used in the analysis (tonnes per year during 40 years):
Steel: 18,70
Copper: 0,30
Stone wool: 0,40
Aluminium: 0,04
Brick: 2,50
Titanium dioxide: 0,11
Ammonia: 0,31
Hydrazine: 0,31
Hydrochloric acid: 21,80
Sodium hydroxide: 21,80
"trinatriumfosfat" 0,18
Lubricating oil: 0,94
Dolomite: 1,18

The following *emission factors* have been used to calculate emissions from operation of the plant. The emission factors are based on data from measurements at trial runs at a 15 MW (thermal effect) experimental plant.
NOx: 50 mg/MJ used fuel, 2,1e-1 g/kWh electricity
SO2: 40 mg/MJ used fuel, 1,69e-1 g/kWh electricity
CO: 10 mg/MJ used fuel, 4,20e-2 g/kWh electricity
Particles: 5 mg/MJ used fuel, 2,10e-1 g/kWh electricity
NH3: 5 ppm mg/MJ used fuel, 3,30e-2 g/kWh electricity
N2O: - mg/MJ used fuel, - g/kWh electricity
CO2: 100000 mg/MJ used fuel, 4,24e2 g/kWh electricity

For electricity used in the manufacture of materials and fuels, *average electricity* for the respective countries distributed on the different electricity production alternatives have been used. The following *degrees of efficiencies* have been used to calculate the fuel used in the electricity production. The values are standard values for existing power plants. New modern plants often have higher degrees of efficiencies. The values are calculated from the effective heat

	value in the used fuels and the energy content in the steam produced in a nuclear power plant. • Coal condensing: 40% • Oil condensing: 40% • Natural gas condensing/combination: 40% • Gas turbine: 25% • Combined heat and power plant(irrespective of fuel) 30% (for electricity production) 85% (total for electricity and heat production) • Water power: are not recalculated, are accounted for as kWh electricity • Nuclear power: 33%, are however not recalculated, but accounted for as kWh electricity or gram natural uranium.
Notes	When wood is extracted, nutritious substances, nitrogen and minerals are extracted at the same time. They would otherwise have been supplied to the forest when the tree dies and are decomposed. The content of nutritious substances are higher in branches and treetops than in the trunk wood. Extraction of felling rests influences the mineral balance negatively. The return of ashes are therefore considered to be a condition for an extensive use of wood fuel. Extraction of nitrogen in combination with return of nutritious substances, e.g. in association with ashes are estimated to give an relief to nitrogen rich forest systems and are estimated to bring about an increased resistance against acidification. Final cutting has a large influence on the landscape through clear-cut forests. The extraction of wood fuel then often has a positive effect on the landscape. Combined heat and power are used as base primarily during the winter half, when the need for both heat and power are the largest.

SPINE LCI dataset: Combustion of bio fuel

Administrative	
Finished	Y
Date Completed	1991
Copyright	
Availability	Public

Technical System	
Name	Combustion of bio fuel
Functional Unit	1 MJ
Functional Unit Explanation	1MJ bio fuel.
Process Type	Gate to gate
Site	Sweden
Sector	Energyware

Owner	Sweden
Technical system description	Combustion of bio fuel at a stationary installation.

System Boundaries	
Nature Boundary	The emissions to air are the only parameters that are studied. No carbon dioxide emissions are accounted to the burning of bio fuels, since the amount of carbon dioxide released in the combustion of biomass was absorbed by the biomass during its lifetime.
Time Boundary	The data are based on conditions and the environmental law valid for 1990.
Geographical Boundary	
Other Boundaries	The bio gas that is incinerated is accounted for.
Allocations	
Systems Expansions	

Flow Data	
General Activity QMetaData	
Date Conceived	1991
Data Type	Unspecified
Represents	See 'Function'.
Method	The data are taken from Tillman, A-M., H Baumann, E. Eriksson, and T. Rydberg, ''Life Cycle Analysis of Selected Packing Materials. Quantification of Environmental Loadings'' Offprint from SOU 1991:77. Chalmers Industriteknik, Göteborg, Sweden 1992.
Literature Reference	Tillman, A-M., H Baumann, E. Eriksson, and T. Rydberg, ''Life Cycle Analysis of Selected Packing Materials. Quantification of Environmental Loadings'' Offprint from SOU 1991:77. Chalmers Industriteknik, Göteborg, Sweden 1992.
Notes	The parameters that are presented are chosen because they have a general interest and because the basis for these parameters are relatively good. All values are reported with 3 figures. The data are however seldom that accurate.

Flow Table and Specific Meta Data

QMetaData	***Direction***	***FlowType***	***Substance***	***Quantity***	***Min***	***Max***	***Unit***	***Environment***	***Geography***
	Input	Refined resource	Bio fuel	1			MJ	Technosphere	
Method: The ash content in wood is 7-15 % by weight. In this case the figure is set to 2%, which is equivalent to 0,10 g/MJ.	Output	Emission	Ash	0.10			g	Air	
Method: According to the Swedish Environmental Protection Board, 0,30-2,00 g CO/MJ applies for wood burnt on a grate, while Bundesamt furUmwelt uses 0,980 g/MJ for wood. In this case the figure 1,00 g/MJ is used.	Output	Emission	CO	1.00			g	Air	
Method: According to the Swedish Environmental Protection Board, 0,007-0,100 g/MJ applies for wood burnt on a grate, while Bundesamt furUmwelt uses 0,176 g/MJ for wood. In this case the figure 0,10 g/MJ is used.	Output	Emission	HC	0.10			g	Air	
Method: According to the Swedish Environmental Protection Board, less than 0,15 g NOx/MJ should be emitted when wood is burnt on a grate, and that the emissions should be comparable in amount with those which occur during the combustion of oil. In this case the figure 0,15 g/MJ is used.	Output	Emission	NOx	0.15			g	Air	
	Output	Emission	Particulates	0.03			g	Air	
Method: According to the law and regulations governing fuels containing sulphur, from 1989, the emission maximum for sulphur is 0.19 sulphur/MJ fuel consumed. This is equivalent to 0,38 g SO2/MJ. For biofuel a figure of 0,031 g SO2/MJ is given in Project kol-Hälsa_Miljö,	Output	Emission	SO2	0.03			g	Air

Applicability	The data can be used, when one wants to estimate the emissions to air caused by combustion of bio fuel at a stationary installation (for exemple an bio fuel driven power plant). The data are valid for Swedish conditions, but can be used as an approximation to other countries. One should though be aware of the fact that the situation in other countries may be very different and depending on this get one gets an unrelyable result. The data are based on old sources and should therefore not be regarded as information describing the current situation. It is difficult to use the data in a correct way, because so little information is given about the system. One of the most important things to know is the efficiency of the plant but even this information is missing.

SPINE LCI dataset: Combustion of waste

Administrative	
Finished	Y
Date Completed	1999-04-19
Copyright	
Availability	public

Technical System	
Name	Combustion of waste
Functional Unit	1 m3 of scrap recieved from Reci Industri Göteborg.

Functional Unit Explanation	See detailed purpose.
Process Type	Gate to grave
Site	GRAAB Box 156 401 22 Göteborg Sweden
Sector	Waste treatment
Owner	GRAAB Box 156 401 22 Göteborg Sweden
Technical system description	At the waste fuelled power plant in Sävenäs about 400.000 tonnes of waste is combusted every year. The energy production per year is about 1 040 GWh heat and 130 GWh electricity. The waste is transported to the facility by truck (Transportation not included in the system). A manually manoeuvred crane feeds the roaster-furnace with waste. The waste is fed on the roaster during the combustion process and the burned-out slag falls down into a water filled slag-distinguishing-basin. The slag is after cooling transported to a deposit-site. The kiln is provided with smoke re-feeder to cut the emissions of especially NOx. To further increase the reduction of NOx, ammonia solution is added during the combustion. The emitted smoke from the combustion is led via a boiler to different steps of smoke purification where heat is extracted. At one step in the smoke purification the smoke is cleansed with water which leaves some of the emissions in a water phase. The polluted water is send to a water cleaning facility before it is let out into Säveån.

System Boundaries	
Nature Boundary	Resources that are not seen as limited in Sweden are neglected e.g. land usage and fresh water. · The electricity utilised by the system is only seen as a resource and the origin is not interpreted. The company is legislated to measure the following emissions: CO Particles NOx HCl Hg Cd Cr Ni Co Pb Dioxin
Time Boundary	The study only deals with retrospective data and no attempts are made to predict future events or conditions. 1997 is assumed as a suitable time frame to collect and interpret data.
Geographical Boundary	The geographical boundary for the converting of waste-oil is set to Sweden.
Other Boundaries	The environmental impact from capital goods and activities serving the process are neglected e.g. personell, infrastructure and facilities. Moreover, maintenance and wear down of the system are neglected. It is assumed that there occurs no spill at the plant.
Allocations	Only impacts caused by the combustion of scrap from Reci Industri are of interest for the study. At Sävenäs various kinds of waste is combusted. It is in many cases impossible to determine its composition. Only the scrap from Reci is of interest, but as it is mixed with other wastes while combusted it is difficult to determine the origin of emissions and what waste contributes to what emission and resource use. The scrap from Reci is in its turn of unknown composition and is only a smaller part of the total amount combusted (160 of totally 381 379 tonnes). The allocation approach is to load emissions and resource use to the scrap based on weight. A deviation to the approach is made concerning the use of fuel oil (Eo4), as the scrap contains fuel oil itself it is not likely to need additional fuel oil to initiate the combustion process. The amount of the heavy metals Co, Be and As in the waste-oil are supposed to be so low that they can be neglected .
Systems Expansions

Date Conceived	1997
Data Type	Unspecified
Represents	See 'Function'.

Method	The general description of the plant is taken from the environmental report of 1997 for GRAAB. Information about the scrap delivered to Sävenäs from Reci is achieved from interviews with Christian Artén, process manager at Reci Göteborg and Bengt Borg production manager at Reci Halmstad. The substances are divided with the amount of recieved waste, 381 379 ton in 1997, to represent the amount per functional unit.

About Inventory

Publication	Master thesis: ''LCA on converted fuel oil'' by Daniel Strandberg and Christer Wik, MSc students Technical environmental planning, Chalmers Univeristy of Technology --- Data documented by: Daniel Strandberg and Christer Wik, MSc students, Technical Environmental Planning, Chalmers University of Technology Documentation reviewed and classified by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology ---
Intended User	Internal use at Reci Industri
General Purpose	The objective of this study was to carry out a Life cycle Assessment for converted fuel oil. The analysis involves outlining the environmental hazardous steps in the production. The result will be used internally to aid as an environmental improving guidance as well as to receive a better view of the process. Externally the result is a part of Reci's ISO 14000 certification, which acts as a guarantee to the customers. The quality of the inquiry is set due to the standards of a Master of Science thesis.
Detailed Purpose	To estimate the resource use and emission released from combustion of scrap, delivered to Sävenäs from Reci Industri.
Commissioner	Schaff, Lars, environmental manager - Reci Industri AB Box 48047 418 21 Göteborg Sweden.
Practitioner	Strandberg, Daniel and Christer Wik - MSc students Technical Environmental Planning Chalmers University of Technology 41296 Göteborg Sweden.
Reviewer	Beckman, Torsten - Technical environmental planning Chalmers University of Technology 412 96 Göteborg Sweden

Applicability	The data are specific for combustion of scrap from Reci Industri.
About Data	Scrap Scrap is delivered to the facility by truck from Reci Göteborg. The scrap is a waste product derived when filtering the waste-oil, it often varies much in its contents, everything from cotton waste to plastic caps. The thing they have in common is that they are smudged with oil and thereby suitable for combustion. Totally about 160 tonnes are delivered (150 from Reci Göteborg and 10 from Reci Halmstad). Calculations · As the content is unknown it is impossible to say what emissions and resource use should be loaded upon the combustion of scrap. The energy content is also hard to predict as the scrap may contain incombustible particles as well. Therefore no calculations have been done beside the allocation approach, as they would be more of assumptions and guesses then representing any actual results. Mass-balance · When calculating on the in and outflow represented in the environmental report no balance of masses is achieved. This is supposed to be caused by the water contents in the delivered wastes. No measurement has been made on water vapour emitted during combustion or the percentage of water in the delivered waste.
Notes	The reviewer acted as supervisor for the Master thesis: ''LCA on converted fuel oil''

SPINE LCI dataset: Combustion of waste oil

Administrative	
Finished	Y
Date Completed	2002-12-18
Copyright	
Availability	Public

Technical System	
Name	Combustion of waste oil
Functional Unit	84 kg oil
Functional Unit Explanation	84 kg was calculated as the yearly used amount at StoraEnso AB in Hyltebruk. The density of the oil is 0.892 kg/l.
Process Type	Unit operation
Site	Slite, Gotland
Sector	
Owner	Slite, Gotland
Technical system description	Discarding of oil used for lubrication is investigated in this data sheet. A tank with lubricating oil is replaced so the waste oil, in this case Mobil DTE PM 220, is discarded. The oil is used as fuel in the cement furnace. The furnace is 1400 degrees Celsius hot and has a 80 meter high chimney so the operation is estimated with combustion of gasoline. The energy content of gasoline is assumed to be 43.8 MJ/kg. Transports are excluded. The oil is filtered to lower the water content before it is burned, but this process is also excluded.

System Boundaries	
Nature Boundary	The lubricant comes from the technosphere. All emissions are air emissions.
Time Boundary	Data is collected autumn 2002. No changes in the procedure are planned for the nearest future.

Geographical Boundary	The combustion takes place at Slite, Gotland.
Other Boundaries	Transports are excluded. The oil is filtered to lower the water content before it is burned, but this process is also excluded.
Allocations	Not applicable
Systems Expansions	Not applicable

About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. -------------------- Data documented by Sandra Häggström, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-03-21
Intended User	Product developer at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The purpose for our study is to compare a coated roller bearing to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is lubricated with a circulating oil system in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Sandra Häggström - .
Reviewer	Olle Ramnäs -
Applicability	Applicable for mineral oils in general if the accuracy of the emissions does not need to be more precise.
About Data	The data is collected from personal communication with Annika Lorin at SAKAB.

SPINE LCI dataset: Combustion of waste to generate heat and electricity

Administrative	
Finished	Y
Date Completed	1996-03-01
Copyright	
Availability	Public

Technical System	
Name	Combustion of waste to generate heat and electricity
Functional Unit	MWh
Functional Unit Explanation	1 MWh extracted heat and energy from the combusted waste. 93,4% heat used for district heating and 6,62% electricity delivered to the power mains. This amount of energy is extracted from 0,38998 ton combusted waste
Process Type	Gate to gate
Site	GRAAB, Sävenäs Box 95 40121 Göteborg Sweden
Sector	Grid electricity and district heat
Owner	GRAAB, Sävenäs Box 95 40121 Göteborg Sweden
Technical system description	The company has a combustion plant, which extracts energy, in form of electricity and district heating, from combustible waste. There is also a sorting plant and a recycling station situated at the site. The thermal energy plant, which combusts waste, in Sävenäs was taken in operation 1972, and today approx. 400 000 ton waste is combusted each year. The combustion resolves in approx. 950 GWh heat and 106 GWh electricity. The waste combusted at the plant is transported to the emptying hall by lorry and emptied into the waste bunker. Some of the waste (mostly coarse building-, demolition- and industrial waste´) is taken to the sorting plant to be sorted and reprocessed before it is transported by a belt conveyor to the waste bunker at the combustion plant. There is also a recycling station at the plant, where households are able to leave recycleble waste duty free. The waste handled in the station is combustible waste, non combustible waste, scrap, hazardous waste, paper, batteries, fluorescent lamp, corrugated cardboard, scrap-elecronics, glass, clothes etc. The ammounts that are handeled in the combustion plant are only the three first categories. A manually manuvered crane feeds the oven with waste via a refill funnel and a refill shaft out on the grate. The waste is feed to the grate during the combustion and the burnt out slag falls down into a trough where the slag is put out. The put out slag is transported out to the slag bunker, where it cools before dumped. Primary air to the combustion is taken from the waste bunker. The air is added to the process under the grate so that the air cools when it passes through the grate blocks. The secondary air constitutes air from the slagg bunker but also recirculated smoke gas. The recirculation increases the surplus of air and therefore also the emission mainly of NOx. To further reduce the emission of NOx an ammonia solution (25% ammonia) is added on the fireplace. Air is added to the walls of the furnace to keep the walls cool and prevent slag from getting stuck on them. This air is taken from the oven house. The fume gas that is made during the combustion passes through an exhaust boiler, a feed water economizer and an electric filter, which is the first step in cleaning the fume gas. After this the gas passes a wet and condensing fume gas cleaner, where a considerable part of the extraction of energy is done. In the smoke gas cleaning plant the gas passes the different steps in the following order: Fume gas economizer, in which the gas emits its heat to the hot water system Quench, which cools the gas with circulating flush water. Washing reactor, in which the gas is cleansed when water is flushed over the gas A condensing reactor, that cleans the gas by condensation. The contaminations and moisture is liquidized. The gained heat is used as a source of heat to the absorption heat pumps. A surplus of water arises in this recirculating system, because of the condensation. This surplus is led to the sewage treatment works and is cleansed. Smoke gas reheater Fume gas fan, whith silencer Smoke stack. From the combustion of waste, heat is produced through a back-pressure condenser and

electricity is produced by a steam turbine.

Technical equipment in the plant

-Combustion

Waste bunker
Usable space: approx. 22 000 m3
11 000 ton waste
14 pcs bunker gate
1 pcs shears, von Rol (1972)

Waste overhead crane
2 pcs overhead crane from Svenska Lyft AB (1084)
2 pcs universal plier bucket (8 m3) from: lifting crane 14 ton

Combustion ovens
Oven 1.
Supplier: von Roll/Kvaerner Enviro Power AB (1994)
Power: 15 ton waste per hour
Thermal heating value: 2,6 MWh per 1 ton waste
Driven by 3-steps plane grate:
The dosage grate is of type length grate
The main grate is of type crosswise grate
Smoke gas recirculation, where 15% of the flow is brought back as secundary combustion air.

Oven 4 and 5
Supplier: von Roll/Kvaerner Enviro Power AB (1972)
Power: 22 ton waste per hour
Thermal heating value: 2,9 MWh per 1 ton waste
Driven by inclined grate, whith puscher
Smoke gas recirculation, where 15% of the flow is brought back as secundary combustion air.

Exhaus steam boiler

Boiler 1.
Supplier: von Roll/Kvaerner Enviro Power AB (1972)
Operating peressure: 20 bar dry, hand steam (212 deg C). Maximum continuous load: 55 ton steam/hour.
Feed watereconomizer (Generator AB, 1982)
Capacity: 2,35 MW, 140-190 deg C
Total power: 33 MW

Boiler 4. and 5.
Supplier: von Roll/Kvaerner Enviro Power AB (1994)
Operating peressure: 40 bar overheated steam (400 deg C). Maximum continuous load: 73 ton steam/hour.
Total power: 58 MW

Cleaning and energy extraction
De-NOx plant
Primar step
Oven 1.
Smoke gas recycling
Supplier: von Roll AG
15% of the flow is brought back as secundary combustion air.
Reduction: approx. 25-30% NOx reduction

Oven 4. and 5.
Smoke gas recycling
Supplier: von Roll AG
25% of the flow is brought back as secundary combustion air.
Reduction: approx. 30% NOx reduction

Secundary step
Boiler 1.
SNCR
Supplier: von Roll AG
Reduction agent: 25% ammonia/water solution
Reduction: approx. 50% NOx reduction

Boiler 4. and 5.
SNCR
Supplier: von Roll AG
Reduction agent: 25% ammonia/water solution
Reduction: approx. 75% NOx reduction

Electric filter

Oven line 1.
Supplier: Svenska Fläkt AB (1972)
With extension (1975)

Reduction:
In-going dust content: approx.4 g / m3
Out-going dust content: approx. 40-80 mg / m3 for dry gas and 10% CO_2

Oven line 4. and 5.
Supplier: von Roll AG / Rothemuhle (1994)
Reduction:
In-going dust content: approx.1-2 g / m3
Out-going dust content: approx. < 25 mg / m3 for dry gas and 10% CO_2

Washing and condensation scrubbs
Manufacture: Götaverken Miljö AB (1988 and 1993)
Three smoke gas cleaning lines, one to each oven line

Cleaning of water (cleaning of process water to recipient)
Manufacture: Götaverken Miljö AB
Two lines with joint sand filter (1988)
Capacity: Maximum 43 m3 / h, normaly 24 m3 / h (8 m3 per hour and oven line)

Steam turbines and turbin condensors belonging to them
Manufacture: AEG Kanis (1988)
Capacity: 14 MW
Turbine condensor
Normal heat production: TG 30,6 MW = 55,5 ton steam
Maximum heat production: 55,2MW = 98,0 ton steam
Production of heat at bypass (the turbine is shut down):
Normal heat production91,0MW = 142,0 ton steam
Maximum heat production: 100,0 MW = 156,0 ton steam

Manufacture: AEG STAL (1995)
Capacity: 35 MW
Turbine condensor
When the turbine is in operation: Condenser power at full load = 73 MW
At by-pass (only heat production): Maximum condenser power = 170 MW

Absorption heat pumps
Manufacture: 4 pcs Sanyo Japan (1988)
Nominal cooling power 3,8 MW each
Maximum cooling power 4,8 MW each

Manufacture: Ahlström (1995)
Nominal cooling power 12,5 MW

Smoke gas economizer
Manufacture: Generator AB (1988)
Exhaustion bioler (hot water eco)
Power: 3,1 MW each

Steam-dump condenser
Manufacture: Götaverken / Martin Larsson (1988)
Steam-dump condenser (20 bar)
Nominal maximum power:141 ton, 90,3 MW
A new steam dump condenser was taken into operation when the new steam system was taken into operation.

Slag / Rest products
Slag bunker: usable volume 1600 m3
Scoop: approx. 3,0 m3 two jaws scoop, lifting capacity 7,3 ton
Slag is feed out of oven 1,2 and 3, through the trough where the slag is put out, by slag chain. From oven 4 and 5 through the slag pucher by the belt conveyor.

Flying ashes/ sludge
Flying ashes are feed through the flying ashes transporter to the two flying ashes silos, each of the volume 85 m3.
From the silos the ashes goes to a moisteriser, where the ashes are mixed with sludge from the water cleansing. The mixing is done intermittently in the daytime.

Smoke stack
The smoke stack consists of 3 separate corten steel pipes, of the hight of 126 m. The duct of the smoke stack has a diameter of 1,6 m.

Ammonia recycling
Supplier: von Roll AG
Ammonia surplus in the processing water is recyced and is added afresh to the SNCR-plant. The plant has a capacity of 2x22 m3 processing water per hour.

Special oven
Manufacture: Bruun & Sörensen
Capacity: 200 kg / h
Support combustion is done with oil-burner
Approx. 150 ton special waste (biological hazardous waste and dead small animals) is combusted per year.
The smoke gas is lead to optional combustion oven for cleaning and extraction of energy.

	Vehicle weighing-machine Manufacture: Fintab 4 pcs with micro computor based system for automatic weighing and registration of waste, slag, scrap etc. Sorting plant Machine equipment supplied by Svenska Fläkt AB (1984) Capacity: 80 000 ton industrial waste per year. Function: A cleansed and reprocessed waste fraction is maintained from industrial waste by means of picking crane, magnet separater, hammer mill, drum sieving sieve, waste shears and so on. Waste bunker: capacity: 1600 m3 (400 ton) Scoop capacity: 8 m3

System Boundaries

Nature Boundary	The company is not obligated to state other emission- or waste substances than the Swedish Environmental Protection law requires.
Time Boundary	The company is obligated to write an Environmental report once every year. Though the legislated limits can be changed only if the activity is changed.
Geographical Boundary	Sweden
Other Boundaries	The amount of the hazardous waste is not specified, but the company states that it consists of lubricating oil, waste oil and other similar rest products from the processes. The waste is taken care of by a hazardous waste disposal company.

About Inventory	
Publication	The environmental report for GRAAB, Sävenäs from 1995, The Board of County in Göteborg and Bohus The Department of Environment -- Data documented by: Maria Erixson and Sara Ågren, project employed for the database projet at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	To show the environmental load
General Purpose	The purpose of the Environmental report is to be the base for permission trial of activities that is harmful to the environment and further to make shore that the company comply with the decision.
Detailed Purpose	To control that the legislated limits are not exceeded.
Commissioner	- The Environmental Administration in the municipality of Göteborg Box 360 401 25 Göteborg Sweden.
Practitioner	Lundgren Christer - GRAAB Box 95 40121 Göteborg Sweden.
Reviewer	- The Environmental Administration in the municipality of Göteborg Box 360 401 25 Göteborg Sweden
Applicability	
About Data	The flow of waste into and out of the system does not quite add up. In the table only show the amounts of waste that is combusted, and the amount of non combustible waste that has been sorted out at the sorting plant. The actual fact is that more flows of waste are involved (among others that from the recycling station). All the information about the flows of waste from the environmental report is shown below: The amount of treated waste Reloaded waste coming from the six different staions situated in Högsbo, Kungälv, Lerum, Mölndal, Kungsbacka and Öckerö: 142806 ton Waste left at the recycling station situated at Sävenäs: Combustible 3202 ton Non combustible 1046 ton Scrap 507 ton Industrial waste sorted at the sorting plant: Non combustible waste 3897 ton Fuel fraction 31775 ton The amount of combusted waste Waste combusted in the waste combustion ovens Reloaded waste 135500 ton Stoared waste fuel 31500 ton Sorted waste 31800 ton Waste directly combusted 166400 ton Waste combusted in the special oven Special waste 125 ton Separate cremations 18 ton The waste from the combustion plant (non combustible) Non combustible waste from the sorting plant 3897 ton Waste from the combustion ovens Slag 75521 ton Flying ashes and sludge 14563 ton Hazardous waste (no amount specified) In the table on the sold energy (the product) is specified, all though this is not the only energy produced. Some of the energy extracted from the waste is used in the process and is therefore not a net product.

	The total energy flow can be seen below: Heat used for district heating (sold product) 874 816 MWh Electricity to the power mains (sold product) 62 017 MWh Internal process consumption (used at Sävenäs) 55 236 MWh Consumption of heat (used in the sorting plant) 1 824 MWh Internal consumption of heat (hot tap water used at Sävenäs) 11 750 MWh Internal consumption of electricity (used at Sävenäs) 43 601 MWh Waste heat (waste when restarting the plant) 8 099 MWh ____ Total energy extraction at the plant + 1 057 313 MWh

Availability	Public

Technical System	
Name	Composting of solid municipal waste
Functional Unit	1 tonne of biowaste
Functional Unit Explanation	1 tonne of biowaste contains 15 weight-% non-recyclable paper and 85 weight-% organic waste (Average values based on O.E.C.D, Environmental Data Compendium, Organisation for Economic Cooperation and Development. Paris, 1997)
Process Type	Gate to gate
Site	Europe
Sector	Waste treatment
Owner	Europe
Technical system description	Composing can be used to treat both organic and non-recyclable paper fractions of solid waste. A compost is the simplest form of biological aerobic treatment. It require regular turning (aeration) to transform organic material to a rich and useful compost. In this system a Windrows process is used. Inflow to the composting process is pre-sorted biowaste (non-recyclable paper and organic waste). Outflows are compost (compost markets are e.g.soil conditioner or improver, soil fertilizer and mulch) and compost residue. Compost residue is defined as residues from biological treatment that cannot be marketed as products due to contamination levels (stone, plastic, metals or textiles) or lack of suitable markets. - Air emissions from the composting: In aerobic treatment processing organic material is broken down directly to carbon dioxide and water. The amount of air emissions per tonne of process input will depend on the moisture content of the incoming material. An average moisture content of 50% can be assumed. (ORCA 1992a). Emissions of volatile compounds as well as CO2 from composting are air emissions in this activity. - Water emissions from the composting: The aqueous effluents reported for biological treatment vary widely in both amounts and composition, depending on both the process used and the feedstock. In composting, considerable evaporation will take place during the process. Any run-off collected is often sprayed back onto the composition material to maintain sufficiently high moisture contents. Waste paper included in the feedstock will absorb much water and therefore little or no leachate is produced. Composting involves a net consumption of energy, consuming process energy and not producing any energy in a usable form. Mass loss due to evaporation and biodegradation of the organic fraction of final vary between 30-60%. Due to the wide range of different composting processes available mass

	loss vary. 50% is a generic value used here. (McDougall, 2001) References: ORCA, Information on Composting and Anaerobic Digestion, ORCA Technical Publication NO.1, Organic Reclamation and Composting Association, Brussels. McDougall F. et al, Integrated Waste Management - a Life Cycle Inventory, Procter & Gamble Technical Centres Limited, Blackwell Science, 2001

System Boundaries

Nature Boundary	A composting plant require a considerable area of land but due to lack of data this is not included in the system. The energy consumption and the emissions to air and water are accounted for. Reported emissions were the ones measured in the study. The fact that emissions on different geographical places can have different effects on the environment has not been accounted for.
Time Boundary	Data are from studies made 1992-2001.
Geographical Boundary	The system is aimed to represent a composting plant in Europe.
Other Boundaries	Subsystems not considered are transports from sorting station to composting area.
Allocations	Not applicable
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	
Data Type	Unspecified
Represents	Combustion of gasoline
Method	All LCI data are taken from the literature references, see specific for more details. Water emission has been estimated using information from Box composting process due to lack of information for the Windrow process. The following water emissions were calculated: COD, BOD, NH4+ and N-total. (Bergmann and Lentz, 1992) Emissions of volatile compounds from composting are presented as different substances and not one group. (De Baere, 1999)

Method: 2.5 % of the organic material and 2.5 % of the paper fractions are added to the residue beacuse it will not be biodegradable and will therefore not be included in the compost . 50% masslost gives 975*0.50= 487.5 kg of produced compost.	Output	Product	Compost	487.5			kg	Technosphere	
Method: 2.5% of the organic material and 2.5% of the paper fractions are not readily biodegradable and are therefore added to the residue.	Output	Residue	Slags and ash	25			kg	Technosphere	

About Inventory	
Publication	McDougall F. et al, Integrated Solid Waste Management - A Life Cycle Inventory, Procter & Gamble Technical Centres Limited, Blackwell Science, 2001 Data documented by: Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, Industrial Environmental Informatics, Chalmers University of Technology Published in SPINE@CPM: 14 August 2002
Intended User	The original study this docume
General Purpose	Data about waste management systems are insufficient and more data are required by the industry.
Detailed Purpose	This documentation is based on a study about Integrated Solid Waste Management performed by Forbes McDougall et al at Procter & Gamble Technical Centres, 2001. The aims of that study was to introduce a LCI model for Integrated Waste Mangement and to provide data that support the concept of Integrated Waste Management as a sustainable method of managing solid waste. The purpose of the documentation of the system has been to make data for waste management available in this format for the industry.
Commissioner	
Practitioner	
Reviewer	
Applicability	This set of data could be applied to a composting plant and it gives a rough estimation of environmental loads of composting. For detailed study of composting more information is needed e.g. regarding feedstock, plant etc. A population of 500 000 in an urban area with a total amount of waste generated of 230 000 tonnes, gives around 28 500 tonnes of biowaste, 4275 tonnes (15 weight-%) of non-recyclable paper and 24 225 tonnes (85 weight-%) of organic material. (McDougall, 2001) In 2000, Renova in Sweden composted 20 000 tonnes of biowaste. For energy consumption the German Government have reported a typical energy consumption of 20 and 50 kWh (electrical energy) per input tonne for plants capable of processing 10 000 tonnes of biowaste per year. The energy consumption of the pre-treatment process will depend on the incoming waste used. Mixed waste, such as Municipal Solid Waste (MSW) will need more extensive sorting per tonne of input with associated energy requirements, than more narrowly defined feedstocks. The energy consumption of the biological treatment process itself will depend on the technology employed. The compost quality is determined by type of incoming waste, type of technology used and level of process control. The major variability occurs in the heavy metal content of the compost. A more mixed feedstock gives higher heavy metal content and a higher level of contamination may mean that no market for this material can be found. It should be remembered that a compost can contain small amounts of heavy metals. The heavy metal content in a compost produced by aerobic process is: Pb 513, Cd 5.5, Cr 71.4, Cu 274, Ni 44.9, Zn 1570, Hg 2.4 (in mg/kg dry wt) (McDougall, 2001) Windrows (static and dynamic) and enclosed vessels are two alternatives for composting. In this system a Windrows process is used, it require more space than enclosed vessels but otherwise they are similar. Windrow composting is also the most common technology used, being least capital intensive.
About Data	Data is based on a study performed by Procter & Gambler about Integrated Waste Management (F. McDougall et al, Procter & Gamble Technical Centres Limited, Blackwell Science, 2001). Data are generally averages, giving an approximate measure of the environment burdens associated with the system. The descriptions of the activity is how it was understood by the person who made the documentation. To calculated CO2- emissions 320 kg per tonnes of wet organic material was used. Water emission has been estimated using information from Box composting process due to lack of information for the Windrow process. The following water emissions were calculated: COD, BOD, NH4+ and N-total. Assumptions have been made by McDougall et al. calculating the amount of residue and produced compost. 2.5 % of the treated organic material and 2.5 % of the treated paper fractions are added to the residue to account for material that are not readily biodegradable. 50 % mass lost gives 975* 0.50= 487.5 kg of produced compost

	Available data on the overall energy consumption for various methods of composting indicated that electrical energy needed for composting is between 18-50 kWh per input tonne. (German Government Report (1993), Energy consumption of various composting plants) (Bergmann and Lentz, Vorstudie zu einer Ökobilanz.., Report, Procter & Gamble GMbH, Schwalbach, Germany, 1992)
Notes	For further information about solid waste managment see: Flemström K., Brief overview of solid waste management, IMI-internal report. The report may be downloaded from: http://www.imi.chalmers.se

SPINE LCI dataset: Connector assembly

Administrative	
Finished	Y
Date Completed	2000-03-09
Copyright	Ericsson
Availability	Official

Technical System	
Name	Connector assembly
Functional Unit	One gram of connector intended for mounting on PC-board
Functional Unit Explanation	The motivation for choosing this functional unit is: · Suitable unit to work with in an LCA of a private branch exchanges (a complicated telecom product) · Important component of the MD110 product system and many other electronic products. These facts are based on Ericsson technical specification of the component. Ericsson product number: RNV 256 201 Ericsson description: Fork connector Connector intended for mounting on PC-board. The plastic leg for mounting in the PC-board shall be of snap in type. The fork connector is angled fed or top fed. PCB thickness 1.6 mm. Suitable plug 390 290/X and 591 484/X. The loose ends of the contact spring shall be guided in slots in the housing. Material Frame: Polyester Contacts: Phosphorous bronze Surface treatment: Contact area: 1.27e-6 m Au on 1.27e-6 m Ni. Soldering tags: 2e-6 m SnPb on 1.27e-6 m Ni. Dimensions: Height: 16.4 mm, Length: 16.6 mm, Width: 14 mm, Terminal thickness: 0.9 mm Weight: 3 g
Process Type	Gate to gate
Site	Not relevant
Sector	Manufacturing
Owner	Not relevant
Technical system description	This activity includes the final assembly of a connector intended for mounting on PC-board. Details on the production are not available. Note; This model is not based on information acquired from connector manufacturers. However, the electricity use for the production has been approximated using information describing other components; a loudspeaker and a push-button switch.

System Boundaries	
Nature Boundary	Emissions to air and water have been excluded due to lack of data.
Time Boundary	1998 The electricity use is based on information acquired in 1998 and they measured in 1998. The raw material use is based on the material declaration for the connector. The material declaration was developed in 1997.
Geographical Boundary	This model is intended to represent the assembly of connector in western Europe.
Other Boundaries	Delimitation's to the system is the final step in the making of the connector. The production of the subparts (e.g. frame, contacts and surface treatment) of the connector is not included in this model. The transportation of them to the factory is not included.
Allocations	Not relevant.
Systems Expansions	None.

Date Conceived	1998
Data Type	Derived, unspecified
Represents	Electricity use for the production of ''Other'' component. See the model ''Other'' electronic components production for further details.
Method	Presented data for raw material input is based on a material declaration for a connector. Only amounts in product are presented, i.e. no waste is included. The electricity use has been approximated using the average electricity use for production of ''other'' components. See Specific QMetaData for Electricty for a further description. Details on the production of ''other'' components can be found in the model ''Other'' electronic components production

Flow Table and Specific Meta Data

QMetaData	***Direction***	***FlowType***	***Substance***	***Quantity***	***Min***	***Max***	***Unit***	***Environment***	***Geography***
Date concieved: 1998 Data type: Derived, unspecified Method: We had earlier made a material declaration of a fork connector by weighing it and looking at the materials stated in the product specification. The total weight was 3.01452 g for one connector. The gold content was 0.002667 g/g. Notes: No eventual material waste included.	Input	Refined resource	Au	0.0027			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: We had earlier made a material declaration of a fork connector by weighing it and looking at the materials stated in the product specification. The total weight was 3.01452 g for one connector. The Cu content was 0.153624 g/g. Notes: No eventual material waste included.	Input	Refined resource	Cu	0.15			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Represents: electricity use for the procuction of ''Other'' component. See the model ''Other component production'' for further details. Method: As we lacked answers for assembly of connector we assumed the same electricity consumption for one gram of connector as for one gram of ''other'' component, i.e. the below mentioned components. Loudspeaker manufacturer	Input	Refined resource	Electricity	6.51			Wh	Technosphere	

states an electricity consumption of 71 Wh for the production of one loudspeaker (''other'' component) which weighs 6,8548 grams. Hence, 71/6,8548 = 10,357 Wh /g other Switch manufacturer states an electricity consumption of 15,2 kJ for the production of one switch (''other'' component) which weighs 1,584 grams. 1 Wh = 3,6 kJ Hence, 15,2/(3,6*1,584) = 2,665 Wh /g other Average value: (10,357 Wh /g other + 2,665 Wh /g other)/2 = 6,51 Wh/g									
Date concieved: 1998 Data type: Derived, unspecified Method: We had earlier made a material declaration of a fork connector by weighing it and looking at the materials stated in the product specification. The total weight was 3.01452 g for one connector. The Ni content was 0.003201 g/g. Notes: No eventual material waste included.	Input	Refined resource	Ni	0.0032			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: We had earlier made a material declaration of a fork connector by weighing it and looking at the materials stated in the product specification. The total weight was 3.01452 g for one connector. The P content was 0.0017 g/g. Notes: No eventual material waste included.	Input	Refined resource	P	0.0017			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: We had earlier made a material declaration of a fork connector by weighing it and looking at the materials stated in the product specification. The total weight was 3.01452 g for one connector. The polyester content was 0.818638 g/g. Notes: The material is glassfilled polyester. Glass fibre amount is 30 % by mass. No eventual material waste included.	Input	Refined resource	Polyester	0.82			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: We had earlier made a material declaration of a fork connector by weighing it and looking at the materials stated in the product specification. About Inventory	
Publication	Not available -- Data documented by: Anders Andrae, Ericsson Business Networks AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The intended use for this LCI

	General Purpose	The general purpose with this LCI model was for application in a LCA project at Ericsson Business Networks. The main goal of the study is; to compare the potential environmental impacts associated with an old (BC 8) and a new model (BC 10) of a private branch exchange (PBX) system, namely the MD110 system, and an additional objective is to include comparisons between different stages of the life cycle (e.g. manufacturing, use and end of life) of the system. The system, PBX MD110, is designed, developed and delivered by Ericsson Enterprise Systems AB. Life-Cycle Assessment methodology (following the ISO14040 standards for LCAs) will be used to determine the environmental impacts. The main purpose of the study for Ericsson is; - to learn, test and evaluate the LCA-methodology as a tool for assessing environmental improvement options in the product design process, and to make up concrete product guidelines regarding design for environment (DfE) and - to evaluate environmental aspects in new design. The relative importance for different life cycle stages may also be an important input in the internal work with an Environmental Management System for Ericsson Enterprise Systems. Another purpose of the study is; to collect and qualify data from suppliers and literature in order to build up a database for this and future LCA activities and within the project, it is also intended to analyse the possibilities to use the study as a base for future work regarding a type III ecolabeling project within Ericsson. The intended audience of the report from the project is; Ericsson's personnel: project management, system management, design, marketing and sales organisation, and thus also (in an extracted version) the Ericsson customers.
	Detailed Purpose	Map a connector manufacturing/assembly process from an environmental standpoint in a structured procedure. The purpose of the project was to collect resource consumption data and emission data connected with the final assembly of connectors and resembling components in our telecom products. The usage for this set of data is life cycle assessments where connectors are part of the studied system. Note: This model is one of in total eighteen models compiled at Ericsson, describing 16 component groups in the PBX. The division into component groups is based on structural resemblance, electrical function and material contents of the different components. -- Below is a list of the component groups and corresponding models that have been compiled: 1. Cables - Model: Cable assembly 2. Capacitors and filters; hole mounted devices - Model: Capacitor for hole mounting assembly 3. Capacitors; surface mounted devices - Model: Capacitor for surface mounting assembly 4. Connectors and holders - Model: Connector assembly 5. Diodes - Model: Diode wafer production and assembly 6. Display units and indicators - Model: Liquid crystal display assembly 7. Microcircuits, oscillators, quartz crystal units and delay lines (2 models) - Models: 1. Integrated circuit capsule assembly and 2. Si wafer production and Si wafer processing for integrated circuits (these models are interlinked) 8. Other - Model: ''Other'' electronic component assembly 9. Potentiometers - Model: Potentiometer assembly 10. Printed boards - Model: Printed board assembly 11. Relays - Model: Relay assembly 12. Resistor networks - Model: Resistor network assembly 13. Resistors, varistors and thermistors; hole mounted devices - Model: Resistor for hole mounting assembly 14. Resistors; surface mounted devices - Model: Resistor for surface mounting assembly 15. Transformers and inductors - Model: Inductor assembly

	16. Transistors and opto couplers (2 models) - Models: 1. Transistor assembly and 2. Si wafer production and Si wafer processing for transistors (these models are interlinked)
Commissioner	- Ericsson .
Practitioner	Andrae, Anders - Ericsson Business Networks AB Augustendalsvägen 21 S-131 89 Stockholm Office: Nacka Strand .
Reviewer	Pålsson, Ann-Christin - CPM Chalmers University of Technology S-412 96 Göteborg Sweden
Applicability	This set of data can be applied to connectors intended for mounting on PC-board in electronic equipment if you know how much the connectors weigh. The model is also intended to be representative for holders in electronic equipment.
About Data	The value for electricity use is based on information acquired from two manufacturers of a loudspeaker and push-button switch, described in the model ''Other electronics production''. The reason for this approximation is that we did not get any usable answer from connector manufacturers. Of all the eighteen models connectors are most similar to the ''other'' components. The raw material input figures have their origin in material declaration of connectors developed at Ericsson. This means that only the amounts included in the product are presented. No waste is included.

Technical System	
Name	Construction of liquid composting batch system. ESA-DBP
Functional Unit	person·year
Functional Unit Explanation	The functional unit chosen is the treatment of one persons sewage and organic waste during one year.
Process Type	Gate to gate
Site	WWTP in Horn, Sweden
Sector	Waste management
Owner	WWTP in Horn, Sweden
Technical system description	Liquid composting batch process was one of the options considered for a little village Horn in the municipality of Västerås, which is a small, planned village of 200 inhabitants situated in a rural area in central Sweden. According to the detailed development plan, 57 houses are to be constructed in this area. The other options were: liquid composting continuous process and conventional waste water treatment plant. The main function of the discussed solution is to treat the toilet and organic kitchen waste. In this solution (excerpt from the report, see 'Publication') ''toilet and kitchen waste is treated batchwise in a liquid composting tank. (...) Grey water (bath, shower and laundry) is treated separately in a sludge separator, filter beds and open ditches. The liquid composted sludge and the filter bed sand are spread on agricultural land.'' The batch system consists of a buffer tank, collection tank and treatment/storage container. ''The composted sludge is pumped to a storage (450 m^3) made of reinforced concrete. The storage is underground, well-covered and mixed in order to minimise emissions of ammonia and methane production. (...) The vacuum unit, the buffer tank and the liquid composting reactor are situated in a building of which is included in the analysis. The building is about 100 m^2 large and consists of a concrete floor, wooden walls and a steel roof and is insulated with stone wool.

	(...) Grey water is transported in a conventional pipe system and treated in a septic tank, sand filters and 40 open ditches before it is released into the lake. One pump station with one pump is estimated to be enough for the small village. The central septic tank (Tremax, ASA 30:25) is designed for 100 pe conventional sewage (black water and grey water). This should be enough considering that it is only grey water that is to be treated. Both the pump station and the septic tank are made of concrete. The electricity demand for pumping wastewater has been calculated for Uppsala city to be 0.8 MJ/m^3. With a grey water production of 55 m^3/pe·y the total electricity demand is 2 500 kWh for Horn village. The sand filters have a total area of 350 m^2 and are provided with two layers of pipes, one for surface distribution of septic tank effluent and one drain system at the bottom of the filter. The PVC pipes are laid in macadam layers (2 x 0.1 m) with 0.8 m sand between.'' This process is included in the system described in: Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/TEP_1997--9.pdf Other processes in the CPM Database also included in the above publication: Operation of waste water treatment plant with urine and sludge separation . ESA-DBP Operation of the sewage sludge and septage treatment system - local treatment option. ESA-DBP Operation of the sewage sludge and septage treatment system - central treatment option. ESA-DBP Operation of small-scale waste water treatment plant. ESA-DBP Operation of liquid composting continuous system. ESA-DBP Operation of liquid composting batch process. ESA-DBP Operation of large scale waste water treatment plant. ESA-DBP Construction of small-scale waste water treatment plant. ESA-DBP Construction of liquid composting continous system. ESA-DBP

System Boundaries

Nature Boundary	Excerpt from the report, see 'Publication': ''The operation of the system concerns first of all the emissions to Lake Freden part of Lake Mälaren. But the operation also has impacts on a larger scale, such as emissions of gaseous pollutants and materials produced in other regions.''
Time Boundary	The data were acquired in 1997 as the most up-to-date ones. Excerpt from the report, see 'Publication': ''The study is made for a wastewater system in a village planned to be built in one or two years. The components of the sanitary system are assumed to have a life time of 15 to 30 years.''
Geographical Boundary	The study was done for the village Horn, Sweden. In the construction analysis it is assumed that most of the equipment is made in Sweden, Norway or Finland.
Other Boundaries	Excerpt from the report, see 'Publication': ''The construction does only include the environmental impacts due to the production of the material and not the use, reuse or disposal of the equipment. (...) The transportation of the material is not included in the analysis. (...) According to the detailed development plan, 57 houses are to be constructed in the property of Horn in Västerås municipality.''
Allocations	No information about the allocation process.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	1997
Data Type	Derived, unspecified
Represents	See 'Function'
Method	Some of the data delivered by local authorities and some adapted from the other report
Literature Reference	Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://www.cpm.chalmers.se/CPMDatabase/DataReferences/TEP_1997--9.pdf
Notes	Production of electricity is not included Local authorities provided site-specific data, while data on equipment were provided by suppliers or estimated from existing systems. General data taken from the literature were used for nutrient content of sewage, the production of precipitation chemicals, fertilizers production, diesel consumption and emissions in the spreading of manure, and the production of different materials.

Intended User	LCA practitioner, Waste Water Treatment System Specialist
General Purpose	Excerpt from the report, see 'Publication': ''The LCAs were performed on planned wastewater systems in areas within three Swedish minicipalities; Luleå, Västerås and Strömstad. Apart from the case studies a literature study of substitutability of nutrients in sewage compared to artificial fertilizers was performed.''
Detailed Purpose	Horn was chosen as an example of small community. Excerpt from the report, see 'Publication': ''This study has been made in order to find out the environmental consequences of two alternatives for the handling of organic waste and sewage for the village of Horn. (...) The question the LCA should answer is: Which technical solution will give the least environmental impact, to treat the toilet and organic kitchen waste by liquid-composting or to treat the wastewater in a small sewage plant and the compostable kitchen waste in a drum compost''

Technical System	
Name	Construction of liquid composting continous system. ESA-DBP
Functional Unit	person·year
Functional Unit Explanation	The functional unit chosen is the treatment of one persons sewage and organic waste during one year. The sewage treatment includes black water and grey water.
Process Type	Gate to gate
Site	WWTP in Horn, Sweden
Sector	Waste management
Owner	WWTP in Horn, Sweden
Technical system description	Liquid composting continuous process was one of the options considered for a little village Horn in the municipality of Västerås, which is a small, planned village of 200 inhabitants situated in a rural area in central Sweden. According to the detailed development plan, 57 houses are to be constructed in this area. The other options were: liquid composting batch process and conventional waste water treatment plant. The main function of the discussed solution is to treat the toilet and organic kitchen waste. In this solution (excerpt from the report, see 'Publication') ''toilet and kitchen waste is treated continuously in a liquid composting reactor. Grey water (bath, shower and laundry) is treated separately in a sludge separator, filter beds and open ditches. The liquid composted sludge and the filter bed sand are spread on agricultural land. The plant consists of the technical components, such as the buffer tank, liquid compost reactor and sludge storage. The most common materials would be aggregates, steel and plastics. ''The vacuum unit, the buffer tank and the liquid composting reactor are situated in a building of which is included in the analysis. The building is about 100 m² large and consists

	of a concrete floor, wooden walls and a steel roof and is insulated with stone wool. (...) Grey water is transported in a conventional pipe system and treated in a septic tank, sand filters and 40 open ditches before it is released into the lake. One pump station with one pump is estimated to be enough for the small village. The central septic tank (Tremax, ASA 30:25) is designed for 100 pe conventional sewage (black water and grey water). This should be enough considering that it is only grey water that is to be treated. Both the pump station and the septic tank are made of concrete. The electricity demand for pumping wastewater has been calculated for Uppsala city to be 0.8 MJ/m³. With a grey water production of 55 m³/pe·y the total electricity demand is 2 500 kWh for Horn village. The sand filters have a total area of 350 m² and are provided with two layers of pipes, one for surface distribution of septic tank effluent and one drain system at the bottom of the filter. The PVC pipes are laid in macadam layers (2 x 0.1 m) with 0.8 m sand between.'' This process is included in the system described in: Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/TEP_1997--9.pdf Other processes in the CPM Database also included in the above publication: Operation of waste water treatment plant with urine and sludge separation . ESA-DBP Operation of the sewage sludge and septage treatment system - local treatment option. ESA-DBP Operation of the sewage sludge and septage treatment system - central treatment option. ESA-DBP Operation of small-scale waste water treatment plant. ESA-DBP Operation of liquid composting continuous system. ESA-DBP Operation of liquid composting batch process. ESA-DBP Operation of large scale waste water treatment plant. ESA-DBP Construction of small-scale waste water treatment plant. ESA-DBP Construction of liquid composting batch system. ESA-DBP

System Boundaries

Nature Boundary	Excerpt from the report, see 'Publication': ''The operation of the system concerns first of all the emissions to Lake Freden part of Lake Mälaren. But the operation also has impacts on a larger scale, such as emissions of gaseous pollutants and materials produced in other regions.''
Time Boundary	The data were acquired in 1997 as the most up-to-date ones. Excerpt from the report, see 'Publication': ''The study is made for a wastewater system in a village planned to be built in one or two years. The components of the sanitary system are assumed to have a life time of 15 to 30 years.''
Geographical Boundary	The study was done for the village Horn, Sweden. In the construction analysis it is assumed that most of the equipment is made in Sweden, Norway or Finland.
Other Boundaries	Excerpt from the report, see 'Publication': ''The production of chemicals and other types of 35 materials needed are included (...). The construction does only include the environmental impacts due to the production of the material and not the use, reuse or disposal of the equipment. (...) The transportation of the material is not included in the analysis.'' Production of electricity is excluded from the study.
Allocations	No information about the allocation process.
Systems Expansions	Not applicable

Intended User	LCA practitioner, Waste Water Treatment System Specialist
General Purpose	Excerpt from the report, see 'Publication': ''The LCAs were performed on planned wastewater systems in areas within three Swedish minicipalities; Luleå, Västerås and Strömstad. Apart from the case studies a literature study of substitutability of nutrients in sewage compared to artificial fertilizers was performed.''
Detailed Purpose	Horn was chosen as an example of small community. Excerpt from the report, see 'Publication': ''This study has been made in order to find out the environmental consequences of two alternatives for the handling of organic waste and sewage for the village of Horn. (...) The question the LCA should answer is: Which technical solution will give the least environmental impact, to treat the toilet and organic kitchen waste by liquid-composting or to treat the wastewater in a small sewage plant and the compostable kitchen waste in a drum compost''
Commissioner	Swedish Environmental Agency - .
Practitioner	Lundin, Margareta - .
Reviewer	Unknown -
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	NB: The results from the project were also used in the following paper: Lundin M., Bengtsson M., Molander S. (2000). Life Cycle Assessment of Wastewater Systems: Influence of System Boundaries and Scale on Calculated Environmental Loads. Technical Environmental Planning, Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://www.cpm.chalmers.se/CPMDatabase/DataReferences/TEP_1997--9.pdf

Technical System	
Name	Construction of small-scale waste water treatment plant. ESA-DBP
Functional Unit	person·year
Functional Unit Explanation	The functional unit chosen is the treatment of one persons sewage and organic waste during one year.
Process Type	Gate to gate
Site	WWTP in Horn, Sweden
Sector	Waste management
Owner	WWTP in Horn, Sweden
Technical system description	Small waste water treatment process was one of the options considered for a little village Horn in the municipality of Västerås, which is a small, planned village of 200 inhabitants situated in a rural area in central Sweden. The other options were: liquid composting continuous process and liquid composting batch

	process. Excerpt from the report, see 'Publication': ''In the (...) WWTP, all wastewater is treated in a small wastewater treatment plant consisting of mechanical, biological and chemical steps. The organic kitchen waste is treated separately in a common drum compost. After storage the sludge is spread on agricultural land while the compost is used in the residents' gardens. The system consists of drum compost container and storage, sewage plant, sludge storage and UV basin. ''The plant is placed in a building (35 m^2) which is included in the analysis. The sludge from the process is pumped to a concrete storage tank (100 m^3). The tank is underground, covered and the sludge is mixed to avoid emissions of NH3, CH4 and odour. Sewage sludge is stored up to one year before it is spread on arable land.'' This process is included in the system described in: Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/TEP_1997--9.pdf Other processes in the CPM Database also included in the above publication: Operation of waste water treatment plant with urine and sludge separation . ESA-DBP Operation of the sewage sludge and septage treatment system - local treatment option. ESA-DBP Operation of the sewage sludge and septage treatment system - central treatment option. ESA-DBP Operation of small-scale waste water treatment plant. ESA-DBP Operation of liquid composting continuous system. ESA-DBP Operation of liquid composting batch process. ESA-DBP Operation of large scale waste water treatment plant. ESA-DBP Construction of liquid composting continous system. ESA-DBP Construction of liquid composting batch system. ESA-DBP

System Boundaries

Nature Boundary	Excerpt from the report, see 'Publication': ''The construction does only include the environmental impacts due to the production of the material and not the use, reuse or disposal of the equipment.''
Time Boundary	The data were acquired in 1997 as the most up-to-date ones. Pumps, tanks, and other technical parts were expected to last for 15 years; buildings, filter beds, and pipes were expected to last for 30 years; and toilets were expected to last for 25 years.
Geographical Boundary	The study was done for the village Horn, Sweden. In the construction analysis it is assumed that most of the equipment is made in Sweden, Norway or Finland.
Other Boundaries	The transportation of the material to the construction site was not included. The construction of UV-basin nor the production and disposal of mercury lamps are either not considered in the study.
Allocations	No information about the allocation process.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	1997
Data Type	Derived, unspecified
Represents	See 'Function'
Method	Some of the data delivered by local authorities and some adapted from the other report
Literature Reference	Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://www.cpm.chalmers.se/CPMDatabase/DataReferences/TEP_1997--9.pdf
Notes	Production of electricity is not included Local authorities provided site-specific data, while data on equipment were provided by suppliers or estimated from existing systems. General data taken from the literature were used for nutrient content of sewage, the production of precipitation chemicals, fertilizers production, diesel consumption and emissions in the spreading of manure, and the production of different materials.

About Inventory

Publication	Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/TEP_1997--9.pdf
Intended User	LCA practitioner, Waste Water Treatment System Specialist
General Purpose	Excerpt from the report, see 'Publication': ''The LCAs were performed on planned wastewater systems in areas within three Swedish minicipalities; Luleå, Västerås and Strömstad. Apart from the case studies a literature study of substitutability of nutrients in sewage compared to artificial fertilizers was performed.''
Detailed Purpose	Horn was chosen as an example of small community. Excerpt from the report, see 'Publication': ''This study has been made in order to find out the environmental consequences of two alternatives for the handling of organic waste and sewage for the village of Horn. (...) The question the LCA should answer is: Which technical solution will give the least

	environmental impact, to treat the toilet and organic kitchen waste by liquid-composting or to treat the wastewater in a small sewage plant and the compostable kitchen waste in a drum compost''
Commissioner	Swedish Environmental Agency - .
Practitioner	Lundin, Margareta - .
Reviewer	Unknown -
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	The results from the study are also discussed in the publication: Lundin M., (1999). Assessment of the Environmental Sustainability of Urban Water Systems. Report TEP 1999:7, ISSN 1400-9560, Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://www.cpm.chalmers.se/CPMDatabase/DataReferences/TEP_1999--7.pdf

Technical System	
Name	Converting waste-oil into fuel oil AGGR
Functional Unit	1 m3 converted fuel oil
Functional Unit Explanation	
Process Type	Gate to gate
Site	
Sector	Waste treatment
Owner	
Technical system description	The waste oil origin from the industries that consume oil products e.g. as lubrication and in cooling processes. A sludge-suction truck generally carries out the local collection. However, the gate of the LCA is located at a later stage where the waste oil is stored in tanks and cisterns. The oil is collected and stored in Stockholm (Loudden), Jönköping, Göteborg, Umeå, Luleå and Halmstad. The waste oil is transported from Umeå and Luleå to Halmstad (Processing waste oil into fuel oil) by train. From Loudden the waste oil is transported to Halmstad by vessel. The waste oil that is collected and stored in Jönköping is transported to Halmstad by truck. The waste oil that is locally collected at the facility in Göteborg (Treatment of waste oil from municipalities, Treatment of oil-contaminated waste water) undergoes a first phase of pre-treatment before being transported to Halmstad by vessel. Some of the waste (scrap) is sent to Sävenäs (Combustion of waste) waste treatment facility for combustion.

When the waste oil is delivered to Halmstad it is evaluated for PCB. The treatment facility in Halmstad does not possess the technique to treat PCB-contaminated waste oil, and is therefore sent to SAKAB in Kumla (Treatment of hazardous waste) for final treatment. This activity is not a standard procedure when producing converted fuel oil and is therefore neglected in the study. The final refinement is achieved in Halmstad, where water and wastes are extracted and the waste oil is converted into fuel oil. The extracted water from the waste oil is treated before being let out to the recipient, the Halmstad harbour. The waste substance (water-sludge) that origins from the water treatment in Halmstad is transported to Göteborg by truck where it is treated in the de-watering facility (De-watering of water-sludge). The solid phase of the water-sludge is discharged at Torsviken. The derived scrap from the treatment process in Halmstad is transported by truck to Reci in Göteborg where the scrap in temporary stored. The scrap is later sent to Sävenäs waste treatment facility. The oil-sludge developed during the oil treatment process in Göteborg and Halmstad is transported by truck to SAKAB for treatment. The converted fuel oil is transported by vessel from Halmstad to the cement production facility at Slite.

General Activity QMetaData

Date Conceived	
Data Type	
Represents	See 'Function'
Method	Some of the data delivered by local authorities and some adapted from the other report
Literature Reference	Bengtsson M., Lundin M., Molander S. (1997). Life Cycle Assessment of Wastewater Systems. Case studies of Conventional Treatment, Urine Sorting and Liquid Composting in Three Swedish Municipalities. Technical Environmental Planning, Report 1997:9, ISSN:1400-9560. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://www.cpm.chalmers.se/CPMDatabase/DataReferences/TEP_1997--9.pdf
Notes	Production of electricity is not included Local authorities provided site-specific data, while data on equipment were provided by suppliers or estimated from existing systems. General data taken from the literature were used for nutrient content of sewage, the production of precipitation chemicals, fertilizers production, diesel consumption and emissions in the spreading of manure, and the production of different materials.

Flow Table and Specific Meta Data

SPINE LCI dataset: Copper alloy casting of block metal from scrap

Administrative	
Finished	Y
Date Completed	1995
Copyright	Metall/ Berlin Metall Verla 1947-
Availability	Full availability

Technical System	
Name	Copper alloy casting of block metal from scrap
Functional Unit	1 kg block metal
Functional Unit Explanation	
Process Type	Gate to gate
Site	Germany
Sector	Materials and components
Owner	Germany
Technical system description	Scrap metal is transported, melted and cast into block metal.

System Boundaries	
Nature Boundary	Not given
Time Boundary	Not given
Geographical Boundary	Germany
Other Boundaries	Not given
Allocations	Not given
Systems Expansions	Not given

Flow Data	
General Activity QMetaData	
Date Conceived	1995
Data Type	Unspecified, expert outspoke
Represents	Average German copper industry
Method	Not given
Literature Reference	K.H. Bruch, D. Gohlke, C. Kögler, J. Kruger, M. Reuter, I. v. Röpenack, E. Rombach, G. Rombach, P. Winkler. Sachbilanz einer Ökobilanz der Kupfererzeugung und - verarbeitung, Teil 1. Metall 49(1995)4, 252-257, Teil 2. Metall 49(1995)5, 318-324, Teil 3. Metall 49(1995)6, 434-440.
Notes	The total primary energy required for transporting, melting and casting of block metal is 9.61 MJ/kg. Mainly fossil fuel heated furnaces are used for block metal production. For electricity a German electricity mix is used and described (in wastes and emissions) as well as the energy from fossil sources. Values in terms of MJ/kg for different transports are given with the specific emissions connected to them. The energy use for a number of help materials is included. Only small amounts of water are used.

About Data	
Notes	If a cradle to gate process is to be calculated data for primary (data set ''High purity copper production from primary raw materials'') or secondary (data set ''High purity copper production from secondary raw materials'') production must be added to the present data. If using primary material data for ore mining and concentration (data set ''Copper ore mining and concentration'') also has to be added. For the primary production of pure copper products 0.57 of the values for ore mining and concentration should be added which for energy is 20MJ/kg. This because the emissions and energy use are expressed per kg copper in concentrate and the copper content is assumed to be 30 weight%. To this the energy for primary production of pure metal 21.8 MJ/kg copper must be added. For secondary production no energy for concentration and mining is used but 20.55 MJ/kg copper is to be added.

Literature Reference	K.H. Bruch, D. Gohlke, C. Kögler, J. Kruger, M. Reuter, I. v. Röpenack, E. Rombach, G. Rombach, P. Winkler. Sachbilanz einer Ökobilanz der Kupfererzeugung und - verarbeitung, Teil 1. Metall 49(1995)4, 252-257, Teil 2. Metall 49(1995)5, 318-324, Teil 3. Metall 49(1995)6, 434-440.
Notes	The total primary energy required for copper wire 8 mm is 3.24 MJ/kg wire. A German electricity mix is used and described (in wastes and emissions) as well as the energy from fossil sources. Values in terms of MJ/km for different transports are given with the specific emissions connected to them. The energy use for a number of help materials is included. 60 g per kg wire is recycled.

Intended User	Life cycle assessments
General Purpose	Increase knowledge about environmental impacts from copper industry
Detailed Purpose	Supply specialists in the field with data for life cycle assessments
Commissioner	- Deutsche Kupfer-Institut Dusseldorf, Wirtshaftsvereinigung Metall e. V. and various industrial companies.
Practitioner	- Institut fur Metallhuttenwesen und Elektrometallurgie der RWTH, Aachen Germany .
Reviewer	- None
Applicability	Can be used for western industrial countries. Best available technology in western Germany.
About Data	
Notes	If a cradle to gate process is to be calculated data for primary (data set ''High purity copper production from primary raw materials'') or secondary (data set ''High purity copper production from secondary raw materials'') production must be added to the present data. If using primary material data for ore mining and concentration (data set ''Copper ore mining and concentration'') also has to be added. For the primary production of pure copper products 0.57 of the values for ore mining and concentration should be added which for energy is 20MJ/kg. This because the emissions and energy use are expressed per kg copper in concentrate and the copper content is assumed to be 30 weight%. To this the energy for primary production of pure metal 21.8 MJ/kg copper must be added. For secondary production no energy for concentration and mining is used but 20.55 MJ/kg copper is to be added.

SPINE LCI dataset: Copper casting, drawing and laquering to 0.6mm wire

Administrative	
Finished	Y
Date Completed	1995
Copyright	Metall/ Berlin Metall Verla 1947-
Availability	Full availability

Technical System	
Name	Copper casting, drawing and laquering to 0.6mm wire
Functional Unit	1 kg 0,6 mm laquer coated copper wire

Functional Unit Explanation	
Process Type	Gate to gate
Site	Germany
Sector	Materials and components
Owner	Germany
Technical system description	Pure metal is transported, melted (most often in gas fired furnaces type ASARCO), cast and formed to 8 mm wire. This wire is then transported again and drawn cold to a dimension of 0.6 mm. The wire is then drawn through a laquer bath and a furnace at 550C.

System Boundaries

General Activity QMetaData

Date Conceived	1995
Data Type	Unspecified, expert outspoke
Represents	German copper industry
Method	Not given
Literature Reference	K.H. Bruch, D. Gohlke, C. Kögler, J. Kruger, M. Reuter, I. v. Röpenack, E. Rombach, G. Rombach, P. Winkler. Sachbilanz einer Ökobilanz der Kupfererzeugung und - verarbeitung, Teil 1. Metall 49(1995)4, 252-257, Teil 2. Metall 49(1995)5, 318-324, Teil 3. Metall 49(1995)6, 434-440.
Notes	The total primary energy required for laquered copper wire 0.6 mm is 8.45 MJ/kg wire. A German electricity mix is used and described (in wastes and emissions) as well as the energy from fossil sources. Values in terms of MJ/km for different transports are given with the specific emissions connected to them. The energy use for a number of help materials is included. 70 g per kg wire is recycled. Approximately 1 ml emulsion per kg produced material is needed and 10 g packaging material. In addition 108 g laquer requiring another 14.67 MJ/kg wire is necessary. Values for the polymer are not included in the data table, but energy values are presented for different coating options in table 16 in the reference.

SPINE LCI dataset: Copper ore concentrate preparation and delivery

Administrative	
Finished	Y
Date Completed	1998
Copyright	The International Copper Association
Availability	Public

Technical System	
Name	Copper ore concentrate preparation and delivery
Functional Unit	1 kg of ore concentrate
Functional Unit Explanation	The material leave this system as ore concentrate.
Process Type	Cradle to gate
Site	Europe
Sector	Materials and components
Owner	Europe
Technical system description	Data received for this study are based on pyrometallurgical operations only. This activity includes 1) Copper ore mining and 2) Copper ore concentrate preparation and delivery. Production and use of electricity and fuel used in the processes are included. Below is a description of the included operations. -- 1) Ore mining -- The copper ore mining method used is determined by the size, shape and depth below the surface of the ore body. Most copper ores are mined by open pit mining in which large quarries are opened, the ore broken away from the deposits by use of explosives and shovelled into trucks. Actual energy requirements vary widely depending on the characteristics of the mine and ore handling techniques used. The type and the amount of ore deposit and the overlying rock and dirt and the depth of the seam below the surface, affect the level of energy needed for mining the ore.

	The data for copper mining have been received from three mining companies. The data cover the mining of 45 million tonnes of ore. -- 2) Ore concentrate preparation and delivery -- It is normal practice for mining companies to prepare or concentrate before shipping to reduce the amount of material to be transported. The data mainly relates to transportation of ore concentrate by rail and sea. Transporting the concentrate by sea is extensive. It is assumed that average shipping and rail transport distances were 10 000 km and 500 km respectively. The data cover the preparation of 2 million tonnes of concentrate.

System Boundaries

Nature Boundary	Some of the data on air and water emissions was provided in a form which made it impractical to calculate emissions for unit mass of product output. For example, from an air emission value given in the units of mg/m3 of air, it is not possible to calculate the total emission unless the total volume of air is known and this is seldom measured in pactice. Therefor, where available, only emission values associated with the given amount of product made are used.
Time Boundary	The data comes from mining companies for the operations during the 12 month period in 1995 (information why the year 1995 was chosen is not available).
Geographical Boundary	The data comes mainly from European operations. Further information of the geographical boundaries is not available.
Other Boundaries	The copper producing industry is international.
Allocations	The first thing that has been done to analyse this system is to break down the complex system into a series of separate sub-systems each of which produces a single product but which, when added together, exhibit the same charateristics as the original single system. In this study has co-product allocation and Stoichiometric allocation been applied. It is not often that practical processes exactly match for example the stoichiometric rules and an alternative method using mass must be applied.
Systems Expansions	Not applied

Flow Data

General Activity QMetaData

Date Conceived	1995
Data Type	Derived, unspecified
Represents	German copper industry
Method	An LCA calculation of the ore concentrate preparation and delivery. The tables that have been used are the tables 34, 36, 37, 38 and 39 in the Eco- profiles of Primary Copper. A report for The International Copper Association, January 1998. For the following subjects has a slightly different name been use here in SPINE compaired from the original tables in the IAC report: In SPINE: In the IAC report: Iron Ore Iron Natural Gas Gas/Condensate NaCl Sodium Chloride HC Hydrocarbons CH4 Methane Cu Cu++/Cu+++ Calcium Ca++ NO3-N NO3- Hazardous waste Regulated chemical
Literature Reference	Eco- profiles of Primary Copper. A report for The International Copper Association, January 1998.
Notes	The total primary energy required for copper tubes is 13.02 MJ/kg tube. Additional 0.5 MJ/kg product for transports of help materials and transports within the companies should be added. A German electricity mix is used and described (in wastes and emissions) as well as the energy from fossil sources. Values in terms of MJ/km for different transports are given with the specific emissions connected to them. The energy use for a number of help materials is included. Approximately 7g oil, 2 g emulsions, 1 g H2SO4, 2 g NaOH and 10 g packaging material is needed for the formning processes.

About Inventory

Publication	Ecoprofile of Primary Copper Production- A report for The International Copper Association By Dr. I. Boustead. 1998. -- Data documented by: Sofia Medin, Electrolux ESD Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	LCA practitioners
General Purpose	The purpose of this work was to produce life-cycle inventory data for the production of primary copper and the sub-processes based on data submitted by members of the International Copper Association from their own operations.
Detailed Purpose	The aim is to provide ''cradle to gate'' data for the ore concentrate preparation and delivery, which is a sub-process in the production of primary copper.
Commissioner	- The International Copper Association .
Practitioner	Boustead, Ian Dr - .

Reviewer	
Applicability	There is no recommendation of how to use the data from this report. This activity is part of a ''cradle to gate'' system for primary copper production. In the sequence of operations leading up to primary copper production there are six main stages involved. These are 1) Copper ore mining; 2) Copper ore concentrate preparation and delivery; 3) Production of matte copper; 4) Production of blister copper; 5) Production of copper anodes and 6) Production of primary copper. This activity only covers the stages 1) copper ore mining and 2) copper ore concentrate preparation and delivery. All six stages in the primary copper production have been described cumulatively in separate activities in the database
About Data	The data used for electricity and fuel production in the calculations leading to the results reported comes from the reports of International Energy Agency. Data Assumptions: Data received from participating companies show sometime wide variation with respect to metal contents of ore and various intermediate products such as concentrates, gas dust and scrap. Therefor has the following assumptions been made: 1. Copper content in ore. Where actual data on copper content of the ore were available these were used. Otherwise the content was calculated on the basis of mass flow. 2. There is also some loss of copper during ore preperation and the smelting and recovery processes. The loss can be calculated from the mass flow if accurate contents of the input and output materials where known.Where this is not possible, the loss is assumed to be 1% at each step of the sequence of operations. It is further assumed that there is another 4% loss of copper during the operational steps from ore preperation to electro-refining, making the total loss of copper to 5%.
Notes	The results in the report of the Ecoprofile study has been broken down into a number of categories, identifying the type of operation that gives rise to them. The categories are: 1. Fuel production 2. Fuel use 3. Process 4. Transport 5. Biomass (inputs and outputs associated with the use of biological materials such as wood).

Technical System	
Name	Copper ore mining
Functional Unit	1 kg of copper ore
Functional Unit Explanation	The metal is leaving this system as copper ore.
Process Type	Cradle to gate
Site	Europe
Sector	Metal and mineral mining
Owner	Europe
Technical system description	Data received for this study are based on pyrometallurgical operations only. This activity covers copper ore mining. Production and use of electricity and fuel used in the process are included.

	The mining method used is determined by the size, shape and depth below the surface of the ore body. Most copper ores are mined by open pit mining in which large quarries are opened, the ore broken away from the deposits by use of explosives and shovelled into trucks. Actual energy requirements vary widely depending on the characteristics of the mine and ore handling techniques used. The type and the amount of ore deposit and the overlying rock and dirt and the depth of the seam below the surface, affect the level of energy needed for mining the ore. The data for copper mining have been received from three mining companies. The data cover the mining of 45 million tonnes of ore.

System Boundaries

Nature Boundary	Some of the data on air and water emissions was provided in a form which made it impractical to calculate emissions for unit mass of product output. Systems Expansions	Not given

Flow Data

General Activity QMetaData

Date Conceived	1992-1994
Data Type	Unspecified, expert outspoke
Represents	Average German copper industry
Method	Not given
Literature Reference	K.H. Bruch, D. Gohlke, C. Kögler, J. Kruger, M. Reuter, I. v. Röpenack, E. Rombach, G. Rombach, P. Winkler. Sachbilanz einer Ökobilanz der Kupfererzeugung und - verarbeitung, Teil 1. Metall 49(1995)4, 252-257, Teil 2. Metall 49(1995)5, 318-324, Teil 3. Metall 49(1995)6, 434-440.
Notes	The values are an average (mine A 14.1%, mine B 24%, mine C 52.6%, mine D 9.2%) of the data for two open-pit and two under ground pits which represent 15% of the world production of copper. The average Cu concentration in those mines is 1,4. The energy use for a number of help materials is included. The total energy use for mining and concentration is 35 MJ (in primary energy as stated in the publication). 10% of the energy used is for the over sea transport. A German electricity mix is used and described (in wastes and emissions) as well as the energy from fossil sources. 1/3 of the primary energy is consumed in mining and 2/3 in concentration. Values in terms of MJ/km for different transports are given with the specific emissions connected to them. In two of the mines 0.03 tons of molybdenum concentrate per ton of copper concentrate is also produced. The copper concentrates contain small amounts of precious metals. Water which is used in the process is to a large extent recycled. Only water losses are given under water use in the data sheet.

Technical System	
Name	Copper production
Functional Unit	kg
Functional Unit Explanation	Inventory result for production of 1 kg copper.
Process Type	Cradle to gate
Site	
Sector	Materials and components
Owner	
Technical system description	BRIEF DESCRIPTION: The processes included in this activity are: Copper mining, concentration, calcination, electric furnace, converter and electrolysis. Ashes is dried and added in the electric furnace. Rich scrap (100% copper) is added in the converter. Other scrap is burned of combustibles in the Kaldofurnace, followed by melting, before it also is added in the converter. PROCESS DESCRIPTION: Copper ore mining The copper ore is mined in Aitik, Sweden, in an open pit mine. The explosives used in the mining are produced at, and transported 300 km by road from, Kimit AB in Kiirunavara, Sweden. Standard distance and modes of conveyance are assumed. The mined copper ore has a content of about 0,35%. Copper ore concentration The ore is concentrated in the ore dressing plant by crushing, grinding and floatation. The dressed ore is transported from the mine in Aitik, Sweden, to the Rönnskär Smelter in Boliden, Sweden for copper production. The distances and modes of conveyance are 20 km by road and 110 km by train. Calcination The ore concentrate is first calcinated in a fluidised bed roaster in 600-700 Celcius degrees. No external heating is required since the process is autogenius and uses heat released at the incineration of sulphur. The calcinated ore accompanies the process gas out of the roaster and is separated from the gas flow in a cyclone separator. Electric furnace The calcianated ore is transported (internally) to the electric furnace, where the material is melted at 1200 Celcius degrees. During the melting two layers are formed, the upper which is the molten slag and the lower which is the molten matte. The molten matte contains 47% copper. (The molten slag contains granite and small amounts of zink and lead. It is not included in this activity. It is transported to the slag refinery, where zink clinker and iron silicate is produced.). Converter

	The molten matte is transported (internally) from the electric furnace to the converter process. In the converter, the copper sulphide is converted to metallic copper in two steps. The concentration of copper after the converter is 98-99% and the formed blister copper is casted to anodes, with a weight of about 330 kg by a piece. To this process step both rich and other scrap are added. Electrolyses The electrolyses is the most time consuming process. It takes 20 days for the anodes to dissolve. The anodes are placed in electrolyses tanks with thin copper plates in between. These thin copper plates serve as cathodes and the pure copper is deposited on them. Two sets of cathode copper, weighing about 145 kg, are formed during the 20 days. The copper has now a purity of 99,95%. The anode remains are returned to the converters, where they are used as cooling scrap. Other scrap is burned of combustibles in the Kaldofurnace, followed by melting, before it is added in the converter.

System Boundaries

Nature Boundary	CRITERIAS USED FOR SELECTING FLOWS: Emissions to air and water, waste and natural resources.
Time Boundary	LIFETIME/APPLICABLE TIME OF SYSTEM/PRODUCT: The data is collected during the early nineties and one should consider that some change in process steps etc. may be done as times go.
Geographical Boundary	GEOGRAPHICAL EXTENSION (for large technical systems) All process steps is situated in Sweden, except for some (about 30%) of the virgin material, which is bought on the open market.
Other Boundaries	NOTES OF RELEVANT INCLUDED FUNCTIONS: Ashes In this study it is assumed that the ashes contain 10% copper. The other 90% is assumed to consist of other useful metals. The secondary ashes are treated as an inflow not traced back to the cradle. Rich scrap Rich scrap is treated as an inflow not traced back to the cradle.
Allocations	PRINCIPLE APPLIED: The allocations in this study is based on massflow (se NOTE further down). DESCRIPTION: Copper production The data for copper production is taken from an environmental report where the production lines are not fully seperated. A seperation has therefore been done between the lines, by using the overall mass balance in the environmental report. In this mass balance all inflows and outflows are specified concerning their contents of the metals Cu, Pb, Zn, Cd, As and Hg. The only metal not specified is Ni. All nickel emissions are allocated to the copper production. NOTE The report, from which this data is taken, has an ambiguity in which allocation method that is used for the copper production process step. It is difficult to say if the allocation is based on massflow or on economical basis. Drying The environmental loadings of ashes are allocated to the copper production by mass, since there is no information of the content of the other 90%. Other scrap The copper content in the other scrap is assumed to be 35,3% and therefor 35,3% of the emissions and energy need is allocated to the copper production. This mass allocation is chosen since there are no information available on the contents of the other 64,7% of the scrap.
Systems Expansions	No.

Date concieved: 1996-05-01 Data type: Derived, unspecified Literature: Life Cycle Assessment of Aluminium, Copper and Steel; Maria Sunér; Chalmers University of Technology; Technical Environmental Planning; Report 1996:6; Göteborg; Sweden	Output	Residue	Waste containing explosives	0.539			g	Other	

About Inventory	
Publication	Life Cycle Assessment of Aluminium, Copper and Steel; Maria Sunér; Technical Environmental Planning; Report 1996:6; Chalmers University of Technology; Gothenburg; Sweden -- Data documented by: Maria Erixon, project employed at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	Life Cycle Assessment-practiti
General Purpose	To make an LCA for Al, Cu and steel.
Detailed Purpose	The data is presented in the report Life Cycle Assessment of Aluminium, Copper and Steel. The purpose of the report was to collect and present inventory data on production and recycling of the three materials aluminium, copper and steel of higher quality than earlier published data.
Commissioner	
Practitioner	Sunér, Maria - Teknisk Miljöplanering Chalmers Tekniska Högskola 412 96 Göteborg Sweden.
Reviewer	
Applicability	CERTAIN CAUTIONS: Almost all data is site-specific and therefore it is not directly applicable in LCA:s requiring average data for metal production.
About Data	GENERAL DATA SOURCE DESCRIPTION: The metal emission to air from the processes Concentration, Calcination, Converter, Electrolyses and Drying are particle bonded, but it is not known if they are included in the parameter particulates. Copper ore concentration Rich scrap It is not known in what chemical form the metal emissions to water are emitted. Calcination It is assumed that there is no mass change in the calcination process, even though sulphur is emitted. Converter process

	The total oil consumption is assumed, together with Boliden AB, to be 708 m3 Eo1/year. Carbon dioxide emissions are calculated from the oil consumption. Electrolyses Assumed amounts of the secondary copper raw materials: Ashes 60% Rich scrap 12% Other scrap 28% Other scrap The total oil consumption is assumed to be 2000 m3 Eo1/year and carbon dioxide emissions are calculated at the Kaldo furnece from the oil consumption.
Notes	

SPINE LCI dataset: Copper rolling to strips

Administrative	
Finished	Y
Date Completed	1995
Copyright	Metall/ Berlin Metall Verla 1947-
Availability	Full availability

Technical System	
Name	Copper rolling to strips
Functional Unit	1 kg of rolled copper strip
Functional Unit Explanation	
Process Type	Gate to gate
Site	Germany
Sector	Materials and components
Owner	Germany
Technical system description	Pure metal is transported, melted (most often in gas fired furnaces type ASARCO), cast and formed to slabs, which after heating to 900C are rolled hot down to 11 mm. After cooling the strips are machined on both sides and cold rolled to strips 0.5x800 mm. Finally the strip coils are annealed. Recyclate and coppercontaining sludge is produced as byproducts.

System Boundaries

Time Boundary	Not given
Geographical Boundary	Germany
Other Boundaries	Not given
Allocations	Not given
Systems Expansions	Not given

Flow Data	
General Activity QMetaData	
Date Conceived	1995

Data Type	Unspecified, expert outspoke
Represents	German average industry
Method	Not given
Literature Reference	K.H. Bruch, D. Gohlke, C. Kögler, J. Kruger, M. Reuter, I. v. Röpenack, E. Rombach, G. Rombach, P. Winkler. Sachbilanz einer Ökobilanz der Kupfererzeugung und - verarbeitung, Teil 1. Metall 49(1995)4, 252-257, Teil 2. Metall 49(1995)5, 318-324, Teil 3. Metall 49(1995)6, 434-440.
Notes	The total primary energy required for copper strips is 7.82-10.42 MJ/kg profile. The variation depends on the casting procedure. Melting in a induction furnace followed by semicontinuous casting requires 4.21 MJ/kg, continuous casting 3.95 MJ/kg, while melting in a gas heated ASARCO furnace followed by continuous casting requires 1.54 MJ/kg. Additional 0.5 MJ/kg product for transports of help materials and transports within the companies should be added. A German electricity mix is used and described (in wastes and emissions) as well as the energy from fossil sources. Values in terms of MJ/km for different transports are given with the specific emissions connected to them. The energy use for a number of help materials is included. Approximately 7g oil, 2 g emulsions, 1 g H2SO4, 2 g NaOH and 10 g packaging material is needed for the forming processes.

About Data	
Notes	If a cradle to gate process is to be calculated data for primary (data set ''High purity copper production from primary raw materials'') or secondary (data set ''High purity copper production from secondary raw materials'') production must be added to the present data. If using primary material data for ore mining and concentration (data set ''Copper ore mining and concentration'') also has to be added. For the primary production of pure copper products 0.57 of the values for ore mining and concentration should be added which for energy is 20MJ/kg. This because the emissions and energy use are expressed per kg copper in concentrate and the copper content is assumed to be 30 weight%. To this the energy for primary production of pure metal 21.8 MJ/kg copper must be added. For secondary production no energy for concentration and mining is used but 20.55 MJ/kg copper is to be added.

SPINE LCI dataset: Cotton (conventional) fibres production. ESA-DBP

Administrative

Finished	Y
Date Completed	2004
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System

Name	Cotton (conventional) fibres production. ESA-DBP
Functional Unit	1 kg of conventional cotton fibres
Functional Unit Explanation	Conventional cultivated cotton is of the annual type (the wild plant is perennial)
Process Type	Gate to gate
Site	Not applicable
Sector	Materials and components
Owner	Not applicable
Technical system description	Cultivated cotton is of the annual type, while the wild plant is perennial. The fibers are attached to the seeds in the seed ball (Wynne, 1997). This process is included in the report 'Methodological issues in the LCA procedure for the textile sector.' Link to report: http://cpmdatabase.cpm.chalmers.se/DataReferences /ESA_2004-7.pdf Other processes in the CPM Database also included in the above publication: 'Cotton covering of sofa. ESA-DBP', 'Flame retardant polyester (Trevira CS) covering of sofa. ESA-DBP' and 'Wool/polyamide covering of sofa. ESA-DBP'.

System Boundaries

Nature Boundary	''Cultivated cotton is of the annual type, while the wild plant is perennial. Cotton can be cultivated in a belt from 35o north to 30o south of the equator. The fibers are attached to the seeds in the seed ball (Wynne, 1997). China and the US produce together about 44% of the world supply (Ellebäk Laursen et al, 1997).''
Time Boundary	Unknown. The importer of data to CPMDatabase makes a qualified guess that the data is produced in the 1990s, based on the publication years of the literature references that are referred to in the report.
Geographical Boundary	''Cultivated cotton is of the annual type, while the wild plant is perennial. Cotton can be cultivated in a belt from 35o north to 30o south of the equator. The fibers are attached to the seeds in the seed ball (Wynne, 1997).'' According to Ellebäk Laursen et al (1997) the values globally may range according to the inventory data in the flow table.
Other Boundaries	Unknown.
Allocations	Not applicable.
Systems Expansions	Not applicable.

Flow Data

General Activity QMetaData

Date Conceived	Unknown.
Data Type	Derived, mixed
Represents	According to Ellebäk Laursen et al (1997) the values, for cotton fibre production, globally may range according to this inventory data.
Method	quantity=arithmetic mean from min max values.
Literature Reference	Dahllöf L, 2004, Methodological issues in the LCA procedure for the textile sector. Environmental Systems Analysis report 2004:7, Chalmers University of Technology, Gothenburg, Sweden http://www.cpm.chalmers.se/CPMDatabase/DataReferences /ESA_2004-7.pdf
Notes	The data for the base case are within this data range (with the assumption that ''water consumption'' includes rainwater). There is no data for emissions of agrochemicals.

Flow Table and Specific Meta Data

About Inventory

Publication	Dahllöf L, 2004, Methodological issues in the LCA procedure for the textile sector. Environmental Systems Analysis report 2004:7, Chalmers University of Technology, Gothenburg, Sweden http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2004-7.pdf
Intended User	LCA practitioners and textile interested parties.
General Purpose	Part of doctoral studies.
Detailed Purpose	The goal of this case study was to identify, map and discuss LCA related methodological issues in the textile sector. This was done through an LCA study, with the goal of ranking three fabrics types for a sofa.
Commissioner	Stiftelsen Svensk Textilforskning - .
Practitioner	Lisbeth Dahllöf - .
Reviewer	Maria Walenius Henriksson - IFP Research AB
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above.
About Data	''Inputs of fertilizers and pesticides were found on the home page of USDA (1999). Data were for Upland cotton, the main type according to the 2000 Crop Production Summary (2001). N, P2O5 and K2O were reported and they were translated to ammonium nitrate, diammonium phosphate and potassium nitrate since LCA data for these chemicals were known for Europe (methodological issue 15, Davis and Haglund 1999). The fertilizers reported are used in Texas (EPA 1999a) but potassium nitrate is the least common, only 0.7% of the potassium is from potassium nitrate. Inputs of pesticides were found from the USDA (1999). Desiccants and defoliation agents are probably included in ''other chemicals'' as well as chemicals for disease control. The herbicide Trifluralin was applied to 74% of the area and the insecticide Malathion was applied to 56% of the area.'' ESA Database Project. Years: 2009-2011. Administering organisation: Chalmers University of Technology, the department of Environmental Systems Analysis. Financier: The Swedish Research Council. Importer of data: Filippa Fuhrman (ESA), assisted by Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	Not applicable.

SPINE LCI dataset: Cotton covering of sofa. ESA-DBP

Availability	Public

Technical System

Name	Cotton covering of sofa. ESA-DBP
Functional Unit	''The functional unit was: surface covering of a 3-seat sofa for private use during 10 years.'' For cotton fabric it is 4.99 kg per sofa.
Functional Unit Explanation	See 'Function'.
Process Type	Cradle to grave
Site	Not applicable
Sector	Consumer goods
Owner	Not applicable
Technical system description	The system is descibed in ''Dahllöf L, 2004, Methodological issues in the LCA procedure for the textile sector - a case study concerning fabrics for a sofa. Environmental Systems Analysis report 2004:7, Chalmers University of Technology, Gothenburg, Sweden'': http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2004--7.pdf Other processes in the CPM Database also included in the above publication: 'Cotton (conventional) fibres production. ESA-DBP', 'Flame retardant polyester (Trevira CS) covering of sofa. ESA-DBP' and 'Wool/polyamide covering of sofa. ESA-DBP'. ''The function was to provide a surface covering for a sofa. The fiber type in this LCA was conventional cotton. The color of the fabric was red. Six laundry washings for the cotton fabric were assumed in order to see the relative environmental importance of the cleaning step. It was assumed that the fabric could be readily removed from the sofa. Incineration at disposal of the fabric used was assumed in the base case (the most probable life cycle chains). Heat recovery and emissions from the incineration were taken into account, but possible oil saving or replacement of other waste in the incinerator was only tested in the sensitivity analysis.'' ''Two Swedish weaving mills willing to participate in this study were found. In figure 2 in the ESA report 2004-7, typical production chains are shown.'' In the litterature reference following processes are included: - Cotton cultivation - Cotton ginning - Cotton baling - Truck driving in Texas - Freighter (cargo ship), large on the Atlantic - Truck from port to Swedish spinning factory - Rotor spinning of cotton - Truck from Swedish spinning plant to weaving plant - Weaving with sizing in Sweden - Travel at work from cotton weaving mills site - Truck from weaving mill to wet treatment plant - Wet treatment and dyeing of cotton fabric - Truck from Swedish wet treatment plant back to weaving mill - Textile distribution at weaving mills site in Sweden - Truck from Swedish weaving mill to upholstery plant - Upholstering of a sofa with cotton fabric - Truck from upholstery site to customer - Use of the sofa - Truck from user to incineration plant - Incineration of cotton fabric

System Boundaries

Nature Boundary	''Mineral resources and water were traced back to their reserves in nature and emissions were followed to air, water or soil. Below are the exceptions found, when the processes were not traced back to the nature reserves or water, or followed to air, water or ground. - A wastewater-treatment plant was included, but the decomposition of each individual chemical was not studied. - The production of the process chemicals and some packaging materials were not within the system boundaries.'' ''Cultivated cotton is of the annual type, while the wild plant is perennial. Cotton can be cultivated in a belt from 35o north to 30o south of the equator. The fibers are attached to the seeds in the seed ball (Wynne, 1997).''
Time Boundary	''Data were collected by interviews from 1999 to 2002, but data from reports ranged from 1993 to 1998. Most reports were from 1997.''
Geographical Boundary	''Cotton: *production of cotton fibers: Texas, USA *yarn production, weaving, wet treatment including dyeing of the fabric, upholstering, use and incineration: Sweden'' ''Cotton was assumed to be cultivated in Texas. The reason for this assumption was that the Swedish cotton spinner bought their cotton mainly from Texas. The US is the second largest

	cotton producer (after China) in the World. China and the US produce together about 44% of the world supply (Ellebäk Laursen et al, 1997).''
Other Boundaries	''The fabrics were assumed to not to be worn out before they were disposed of, a realistic scenario for Swedish conditions. Therefore the abrasion resistance was not taken into consideration in the study, while the effect of different lifetimes of the fabrics is discussed in chapter 4.3.7.'' ''Truck driving in Texas The distance was assumed to 300 km. This distance is assumed to be an average from the ginning plants to Houston. Medium truck (total weight: 24 tons, maximum load: 14 tons), fulfilling the ''Euro 1'' emission regulations (1993-1995), load factor 50% and rural driving mode were assumed.'' ''Freighter (cargo ship), large on the Atlantic The distance Houston-Gothenburg was estimated to 10,279 km. The cotton bales are in containers on freighters. The spinning company sets no demands regarding which fuel should be used by the freighter (Importer 2000). ''Truck from port to Swedish spinning factory The distance was assumed to about 80 km and medium truck (total weight: 24 tons, maximum load: 14 tons), fulfilling the ''Euro 2'' emission regulations (1996-), load factor 50% and rural driving mode were assumed.'' ''Rotor spinning of cotton The data were derived from a spinning and weaving mill (2000) for cotton. Comparisons were made with literature. The spinning mill did also weaving. - About cardboard and polypropylene: data come from another cotton weaving mill. They claim that cotton thread comes with one time use pallet (wood), which contains 9 boxes with 12 cones per box. One cone weights 65 g and contains 800 g thread. The cone was assumed to be made of polypropylene. The box is made of cardboard and has an estimated weight of 300 g. Note that in this study only the production of the polymers are included, not the plastic items. - Wood was included, but not the production of the pallet. - In the past, byssinosis, a respiratory disorder caused by dust from cotton and other fibers (Encyclopædia Britannica April 2003) was a problem associated with bale opening, but now the process has been automated, and the problem has disappeared. - Workers must wear ear protection. The noise level is 89-95 dB. There were no problems with impaired hearing among the workers. Therefore this was not reported. - Water is used for air conditioning. Here it was assumed to 0 since all water was allocated to the weaving activity, which was in the same mill. For this study this is not important, but it would have been better for the activities to share 50% of the water consumption each. - Personnel travel at work was not known, but was probably low and therefore not reported.'' ''Truck from Swedish spinning plant to weaving plant The distance was assumed to about 30 km.'' ''Weaving with sizing in Sweden Weaving includes warping, dressing, weaving and inspection.'' ''Truck from weaving mill to wet treatment plant The distance was assumed to 30 km.'' ''Wet treatment and dyeing of cotton fabric - Business trips are included, but both wet treatment mills claim there are hardly any business trips; therefore data were assumed to be 0. - Chemicals for the machines were included, but according to one wet treatment mill, the value is insignificant, therefore it was assumed to 0. - The fixation grade of the dyeing agents was reported from one wet treatment mill to be 75%. Where no concentration of the color is reported, a concentration of 50% was assumed. Perfluoric acids, fluor polymer emulsion and nonionic emulsifier were assumed to fixate at 100%. This gave a total of 16.33 g chemical loss/kg undyed fabrics.'' ''Truck from Swedish wet treatment plant back to weaving mill The distance was assumed to 30 km.'' ''Textile distribution at weaving mills site in Sweden Energy and water consumption was considered to be insignificant.'' ''Truck from Swedish weaving mill to upholstery plant The distance was assumed to 500 km.'' ''Upholstering of a sofa with cotton fabric - Energy used was derived from the working time. Two upholstery companies have answered that about 3 hours are used. Assumptions regarding sewing machines, heating and general electricity were made. - The fabric share of the general energy requirement for the production of a sofa was assumed to 25%.'' ''Use of the sofa It was assumed that the fabric is laundered six times during its lifetime. Data regarding chemical use came from Pulli (1997), where environmental impact of a cotton T-shirt was reported. For the fabrics it was assumed that the machine is filled to maximum and the ironing time is half the time of ironing a cotton T-shirt. Tumble-drying was included. It is

	not clear from the report which machine type was reported, but energy data combined with water consumption indicated an old machine, washing at 40 0C. '' ''Truck from user to incineration plant Light truck with maximum 14 tons weight, 50% load was assumed. The truck was assumed to be set according to the Euro2 emissions regulations. The distance was assumed to 50 km in urban area. Empty return was assumed; therefore the distance to the incineration plant was assumed to 25 km.'' ''Incineration of cotton fabric Heat recovery regards cotton fabric combustion (Ellebäk Laursen et al1997).''
Allocations	''Weaving with sizing in Sweden - Allocation: All energy and material was allocated to the fabrics without the spillage (thus considered to have zero value, although it can be used for furniture upholstery). - Data for water for sizing and moisture came from one cotton-weaving mill, and all water was allocated to the weaving mill. The amount that does not go to the wastewater-treatment plant is water that has evaporated. The water amount to wastewater-treatment plant was an estimate. In the original data, water was assumed to unknown type, but a realistic estimate is that industrial water was used, here set to drinking water.'' ''Textile distribution at weaving mills site in Sweden Allocation was only to dyed and finished fabric with packaging and not samples, except for input of packaging material, which was allocated to both samples and product.'' ''The allocation procedure by mass was not uniform in applications. The deviations were as follows: - No flows were allocated to waste, such as edge strips from weaving or cardboard or textile samples. - In the weaving operation, allocation was made per meter fabric. - Allocations for light fuel oil, heavy fuel oil, LPG and natural gas production were not known as well as for electricity from natural gas or oil and production of sodium hydroxide and ethylene glycol used for the sensitivity analysis. - For electricity production (Swedish average) the allocation between recycling and virgin materials was according to the 50/50 method. When heat was also produced, the allocation was according to energy output. - For electricity (European average), exergy values were used to allocate between electricity and heat.''
Systems Expansions	''In the life cycle of the cotton fabric, 10.1 kg cottonseed is also generated, but is not an output here because its benefit is calculated (system expansion).'' ''System expansion: 66% of the seed cotton is cotton seed, which gives oil, meal, hulls and linters (short fuzz fibers), which were treated by system expansion.'' ''Incineration of cotton fabric Only one aspect of system expansion is taken into consideration here: the heat recovery. The heat created was assumed to be used for e.g. district heating. If the incineration replaces oil combustion, the carbon dioxide emission would be negative and the SOx emission would be less, but if it replaces other waste, some methane emission would also have to be added in the table, since materials on landfills create methane. (The replacement of other waste can be approximated with the landfill of fabric scenario in the sensitivity analysis.)''

Flow Data

General Activity QMetaData

Date Conceived	Unknown
Data Type	Calculated
Represents	See 'Function'.
Method	The data is produced with the software tool LCAit.
Literature Reference	Dahllöf L, 2004, Methodological issues in the LCA procedure for the textile sector - a case study concerning fabrics for a sofa. About Inventory

Publication	Dahllöf L, 2004, Methodological issues in the LCA procedure for the textile sector - a case study concerning fabrics for a sofa. Environmental Systems Analysis report 2004:7, Chalmers University of Technology, Gothenburg, Sweden http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2004-7.pdf
Intended User	LCA and textile practitioners
General Purpose	Part of doctoral studies. ''The overall purpose of the studies is to give suggestions for solving some of the methodological issues within the LCA method when used in the field of textiles.''
Detailed Purpose	''The goal of this case study was to identify, map and discuss LCA methodological issues in the textile sector. This was done by carrying out an LCA study with the goal of ranking three fabric types for a sofa. i) The main reason for carrying out the study was that the LCA methodology is not fully developed and different sectors have different method development needs. This work was being done on the basis of interest from the textile industry in Sweden. ii) The study could be used for further development regarding methodological issues in the efforts to establish Product Specific Rules (PSRs) for Certified Environmental Declarations (EPDs) in the textile sector (the Swedish Environmental Management Council 2000) and for the modification

	work of the ISO 14040 (1997) - ISO 14043 (2000) standards. iii) It is intended to be used by purchasers, designers, etc., in the textile industry as well as for researchers and others working with the ISO 14040 (1997) - ISO 14043 (2000) standards.''
Commissioner	Stiftelsen Svensk Textilforskning - .
Practitioner	Lisbeth Dahllöf - .
Reviewer	Maria Walenius Henriksson - IFP Research AB
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above.
About Data	''Cotton cultivation - Inputs of fertilizers and pesticides were found on the home page of USDA (1999). Data were for Upland cotton, the main type according to the 2000 Crop Production Summary (2001). N, P2O5 and K2O were reported and they were translated to ammonium nitrate, diammonium phosphate and potassium nitrate since LCA data for these chemicals were known for Europe (methodological issue 15, Davis and Haglund 1999). The fertilizers reported are used in Texas (EPA 1999a) but potassium nitrate is the least common, only 0.7% of the potassium is from potassium nitrate.'' - Inputs of pesticides were found from the USDA (1999). Desiccants and defoliation agents are probably included in ''other chemicals'' as well as chemicals for disease control. The herbicide Trifluralin was applied to 74% of the area and the insecticide Malathion was applied to 56% of the area.'' ''Cotton bailing - The weight of packaging material and chlorinated phenol were not known but these are used in practice (Ellebäk Laursen et al1997).'' ''Weaving with sizing in Sweden - Liquefied petroleum gas (LPG), light fuel oil, starch: data comes from one cotton-weaving mill. The values of these flows were divided 50:50 between weaving and spinning. Although the representative from the weaving mill actually mentioned propane, here it is approximated to LPG. Not all weaving mills use LPG, it could therefore sometimes be left out. Here it is included, but the amount is not crucial to this study. - Data for lubricant oil is also a mean value from the three weaving mills. Grease usage is a mean value from two weaving mills. The amount/m was divided by the mean value for cotton weight derived from two cotton-weaving mills and a cotton wet treatment mill, 525 g/m (150 cm wide). - The fact that a mean value for the three fiber types was used in the calculation gave the effect of slightly different values for the flows of each fiber, since 10m fabrics is used for a sofa but the fabric is reported by weight (Data of weight of fabric used: cotton: 463-525 g/m, Trevira CS 373 g/m, Wool/PA 560 g/m, average value 465 g/m (150 cm wide)). This was corrected by setting factors for the different fibers on each side of the weaving activity, e g for Trevira CS: 465/373 before the weaving and 373/465 after the weaving. This resulted in inventory data per meter fabrics (and not per kg).'' ''Travel at work from cotton weaving mills site This activity deals with personnel travel in order to sell and inform about the fabric. Travel information given on an annual basis was translated into travel per m fabric made (including samples). The value 0.35 vkm/m fabric (vkm=vehicle km) was calculated from information from three weaving mill to be 0.67 vkm/kg cotton. Two of them also reported travel by air (0.07 vkm/m fabric) and one also reported train transport. Here only car transport was used. In the concept ''vkm'' it is assumed that about 1.6 people travel in each car (INFRAS 2000).'' ''Wet treatment and dyeing of cotton fabric Following steps were included: Singeing, desizing, washing, bleaching with H2O2, washing, mercerization, washing, dyeing, washing, finishing. The dyeing machine is a cold foulard and the dyeing agents are reactive. - Data are an average from 2 wet treatment mills and dyers of cotton, if not specifically noted under the table. One of the two had specific data for energy and chemical consumption for each step, but the other had only chemical consumption for each step and not specific energy use for the fabric. The lower energy value is from the plant, which knew the energy use for each process step. The plant, which only had data for total energy use, mainly has processes similar to this, although the specific red fabric had a more complicated wet treatment cycle than the average fabric types. Therefore the calculated average energy value is probably an underestimation for this red fabric. - Values for emissions were only available as plant totals. Therefore these data are a combination: chemicals use was for a specific fabric from one wet treatment mill. Water and energy use was for a specific fabric, for one wet treatment mill, and for the other it was derived from the total water and energy respectively, used in the factory (allocation on mass fabric; the economic value for the fabrics are similar (methodological issue 14)). One factory uses tap water, the other water from a river. Data were an average for the year 2000. - Packaging material for delivery back to weaving mill plant was collected from a third wet treatment mill (treats polyester and wool fabrics). - The production manager for one plant reported that Cu discharges to water were mainly from the equipment, and therefore it was not reported here. Dyeing agents fixate to about 75%, most of the rest is trapped in the sludge in either the plant or in the municipal wastewater-treatment plant. These 25% are added manually in appendix 1. All reported contents in sludge are derived from total amounts for the factory.'' ''Textile distribution at weaving mills site in Sweden Data about samples come from 2 weaving mills. Data about packaging material come from one weaving mill. Often the cardboard rolls are reused for the same application, but here it is assumed that the cardboards is reused elsewhere. The packaging used and total fabrics produced were known (both Trevira CS and Wool/PA).''

	""Upholstering of a sofa with cotton fabric Data regarding amount of fabric and spillage came from two upholstery companies." "Incineration of cotton fabric Emissions are general data for textiles incinerated in Sweden (Sundqvist 1999)." —— ESA Database Project. Years: 2009-2011. Administering organisation: Chalmers University of Technology, the department of Environmental Systems Analysis. Financier: The Swedish Research Council. Importer of data: Filippa Fuhrman (ESA), assisted by Johan Tivander (ESA). Technical System	
Name	Cultivation and felling of trees for papermaking. ESA-DBP
Functional Unit	1 m3sub
Functional Unit Explanation	Excerpt from the report, see 'Publication': ''The unit used by forestry industry is for birchwood, m3sub, is a cubic meter of solid under bark wood substance. The weight of one m3sub of birch is in between 430-480kg. (...) For the calculations an average of 455 kg has been used.''
Process Type	Cradle to gate
Site	Unknown
Sector	Wood and wooden products excl. Furniture
Owner	Unknown
Technical system description	Excerpt from the report, see 'Publication': ''Hardwood is a merchandise name for trees with flat fibres. The most important source, for Swedish forestry, of hardwood is eucalyptus grown in South America. Hardwood contributes with over 50%, but no data are available for this source, why Swedish birch has been assumed to be the source. Birch is a by-product in the Swedish forestry. It is the first plant that grows after harversting a forest and later cut down to give room for the trees the forester intend to grow on the land. (...) The data includes the cultivation, felling and transportation of logs to a road.'' This process is included in the system described in: Beckman T. (1997). Gutenberg versus IT. A Life Cycle Assessment of printed and CD-stored information. Technical Environmental Planning, Report 1997:3, Chalmers University of Technology. Gothenburg, Sweden. Other processes in the CPM Database also included in the above publication: - Manufacturing of CD-R (Compact Disc-Recordable). ESA-DBP - Manufacturing of CD-ROM (Compact Disc - Read Only Memory). ESA-DBP - Dioctyl phthalate (DOP) production. ESA-DBP - Cardboard production (MDF based). ESA-DBP - Production of copypaper. ESA-DBP - Production of orthoxylene. ESA-DBP

Literature Reference	Swedish Pulp and Paper Research Institute (STFI) database (1996), Sweden
Notes	In the life cycle of the cotton fabric, 10.1 kg cottonseed is also generated, but is not an output here because its benefit is calculated (system expansion). This data set is generated with the software LCAit. All values that are below 0.001 kg and values given in the unit Bq are excluded. These values can be found in the litterature reference.

About Inventory

Publication	Beckman T. (1997). Gutenberg versus IT. A Life Cycle Assessment of printed and CD-stored information. Technical Environmental Planning, Report 1997:3, Chalmers University of Technology. Gothenburg, Sweden.
Intended User	LCA practitioner
General Purpose	The study was done for the purpose of master thesis.
Detailed Purpose	Excerpt from the report: ''The goal of this study is to undertake an life cycle assessment (LCA) of different alternatives for Ericsson to provide their customers with reference libraries to the Ericsson Consolo MD110 telephone exchange system. The different documentation alternatives investigated in this study are: plastic ring binders, paperbacks, CD-R records and CD-ROM records.''
Commissioner	Unknown - .
Practitioner	Torsten Beckman - .
Reviewer	Henrikke Baumann, - Environmental Systems Analysis, Chalmers University of Technology
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	NB: The inventory results for the whole life cycle (from cradle to grave) of binders, paperbacks, CD-Rs and CD-ROMs can be found in the reference report.

SPINE LCI dataset: CuNi10Fe extrusion and drawing of tubes

Administrative

Finished	Y
Date Completed	1995
Copyright	Metall/ Berlin Metall Verla 1947-

Availability	Full availability

Technical System

Name	CuNi10Fe extrusion and drawing of tubes
Functional Unit	1 kg CuNi10Fe tubes
Functional Unit Explanation	
Process Type	Gate to gate
Site	Germany
Sector	Materials and components
Owner	Germany
Technical system description	Pure metal is transported, melted in an induction furnace, alloying elements are added and the alloy is cast semi continually into bars. The bars are heated to 1000C and extruded over a core and then drawn cold. After an anneal the tubes are drawn to the final dimension of diameter 15 mm and 1 mm thickness. Coppercontaining sludge is a byproduct. 1.17 kg per kg product is recycled (0.3 in the melting and casting process and 0.87 kg in the forming process).

System Boundaries

Nature Boundary	Not given
Time Boundary	Not given
Geographical Boundary	Germany
Other Boundaries	Not given
Allocations	Not given
Systems Expansions	Not given

Flow Data

General Activity QMetaData

Date Conceived	1995
Data Type	Unspecified, expert outspoke
Represents	German average industry
Method	Not given
Literature Reference	K.H. Bruch, D. Gohlke, C. Kögler, J. Kruger, M. Reuter, I. v. Röpenack, E. Rombach, G. Rombach, P. Winkler. Sachbilanz einer Ökobilanz der Kupfererzeugung und - verarbeitung, Teil 1. Metall 49(1995)4, 252-257, Teil 2. Metall 49(1995)5, 318-324, Teil 3. Metall 49(1995)6, 434-440.
Notes	The total primary energy required for transporting, melting, casting and forming CuNi10Fe by drawing to tubes is 32.2 MJ/kg product. Of this energy 16.2 is associated with the melting and casting and 16.0 with the forming processes. This takes also the recyclate into consideration. An additional 0.4 MJ/kg has to be added for transport of additives and 0.1MJ/kg for transports within the company. A German electricity mix is used and described (in wastes and emissions) as well as the energy from fossil sources. Values in terms of MJ/km for different transports are given with the specific emissions connected to them. The energy use for a number of help materials is included.

Applicability	Can be used for western industrial countries. Best available technology in western Germany.
About Data	
Notes	If a cradle to gate process is to be calculated data for primary (data set ''High purity copper production from primary raw materials'') or secondary (data set ''High purity copper production from secondary raw materials'') production must be added to the present data. If using primary material data for ore mining and concentration (data set ''Copper ore mining and concentration'') also has to be added. For the primary production of pure copper products 0.57 of the values for ore mining and concentration should be added which for energy is 20MJ/kg. This because the emissions and energy use are expressed per kg copper in concentrate and the copper content is assumed to be 30 weight%. To this the energy for primary production of pure metal 21.8 MJ/kg copper must be added. For secondary production no energy for concentration and mining is used but 20.55 MJ/kg copper is to be added. For alloys additional energy has to be included for the manufacturing of the additives. A CuNi10Fe alloy consists of 89 w% Cu, 10 w% Ni and 1 w% Fe. This means that 0.89 of the primary energy for the above primary or secondary copper process has to be added (primary:37.2MJ, secondary:18.3MJ). The energy for production of nickel is 165 MJ/kg and steel 28 MJ/kg. In total this means adding 16.5 MJ for the nickel and 0.3 MJ for the iron. In total the primary energy to be added to cover the cradle to gate process is 54 MJ/kg CuNi10Fe for primary production and 35.1 MJ/kg CuNi10Fe for secondary production (alloying elements still primary production only copper secondary) The same procedure can be used to add emissions and other information for the production of alloys.

SPINE LCI dataset: CuNi10Fe extrusion and pilgering of tubes

Metall 49(1995)6, 434-440. --- Data documented by: Alena Ashkin, ABB Corporate Research Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology ---
Intended User	Life cycle assessments
General Purpose	Increase knowledge about environmental impacts from copper industry
Detailed Purpose	Supply specialists in the field with data for life cycle assessments
Commissioner	- Deutsche Kupfer-Institut Dusseldorf, Wirtshaftsvereinigung Metall e. V. and various industrial companies.
Practitioner	- Institut fur Metallhuttenwesen und Elektrometallurgie der RWTH, Aachen Germany .
Reviewer	- None
Applicability	Can be used for western industrial countries. Best available technology in western Germany.
About Data	
Notes	If a cradle to gate process is to be calculated data for primary (data set ''High purity copper production from primary raw materials'') or secondary (data set ''High purity copper production from secondary raw materials'') production must be added to the present data. If using primary material data for ore mining and concentration (data set ''Copper ore mining and concentration'') also has to be added. For the primary production of pure copper products 0.57 of the values for ore mining and concentration should be added which for energy is 20MJ/kg. This because the emissions and energy use are expressed per kg copper in concentrate and the copper content is assumed to be 30 weight%. To this the energy for primary production of pure metal 21.8 MJ/kg copper must be added. For secondary production no energy for concentration and mining is used but 20.55 MJ/kg copper is to be added. For alloys additional energy has to be included for the manufacturing of the additives. A CuSn6 alloy consists of 94 w% Cu and 6w% Sn. This means that 0.94 of the primary energy for the above primary or secondary copper process has to be added (primary:39.3 MJ, secondary:19.3 MJ). The energy for production of tin is 70 MJ/kg. In total this means adding 4.2 MJ for the tin. In total the primary energy to be added to cover the cradle to gate process is 43.5 MJ/kg CuSn6 for primary production and 23.5 MJ/kg CuSn6

		for secondary production (alloying element still primary production only copper secondary). The same procedure can be used to add emissions and other information for the production of alloys.

SPINE LCI dataset: CuSn6 continuous casting

Administrative	
Finished	Y
Date Completed	1995

SPINE LCI dataset: Cutting of steel bars (117x147 mm)

Administrative

Finished	Y
Date Completed	02-12-31
Copyright	
Availability	Public

Technical System

Name	Cutting of steel bars (117x147 mm)
Functional Unit	One cut steel bar, 12.4 kg
Functional Unit Explanation	For the manufacturing of one bearing roller, one cut steel bar is needed. The cut steel bar has the dimensions 117 x 147 mm and weighs 12,4 kg. One SKF spherical roller bearing 232/530 consists of following components: 1. one inner ring 2. one outer ring 3. one guide ring 4. one brass cage 5. 36 bearing rollers (coated or non-coated)
Process Type	Unit operation
Site	Sweden
Sector	Materials and components
Owner	Sweden
Technical system description	This activity is a sub-process step to the system ''Production of bearing rollers (à 9,2 kg)'' which can be found in the SPINE@CPM database. In this activity, steel bars with diameter 117 mm is cut into pieces (117 x 147 mm). These pieces are raw material for the production of bearing rollers at SKF in Göteborg. The steel bars are produced at the Stockbridge Works in Sheffield by Corus Engineering Steels, and are transported from Sheffield in England to Kode in Sweden for this cutting process (described in this activity) and then finally to SKF in Göteborg for further processing into bearing rollers. In this dataset the energy consumption for the cutting process in Kode, Sweden, is reported. Also internal transport by dieseltruck (15 seconds for each cut piece) and consumption of cutting fluid is reported.

System Boundaries

Nature Boundary	Emissions to air and water are not measured and could therefore not be reported in this dataset. The steel bars used for the rollers come from Corus Engineering Steel in Sheffield. The steel bars are 100 % made from scrap and is not seen as a resource, but comes from the technosphere. The steel scrap from the cutting process is assumed to be sent for deposition, since no data about recycling has been obtained. It ends therefore as waste in the technosphere. The cutting fluid has not been traced from the cradle or to the grave, because of lack of data.
Time Boundary	The data was collected during the autumn 2002.
Geographical Boundary	The cutting process takes place in Kode, in Sweden.
Other Boundaries	Internal transport within the cutting site in Kode is included in the study (=15 seconds). Assumptions were made at BeTe Trucks AB in Sweden how much energy a dieseltruck consume per hour (= 6 litres/h (average value)). The heating value for diesel (= 35, 31 MJ/litre) was found at Internet: www.fast-tech.com and the diesel consumption could be calculated to 0,88275 MJ/15 s. The diesel production is NOT included in the dataset. The electricity production is NOT included in this study.
Allocations	Allocations have been made according to weight and production.
Systems Expansions	Not applicable

About Inventory

Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Technology, December 2002. ----------- Data documented by Helene Berg, M Sc. student at Chalmers University of Technology and SKF. Data reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-02-18.
Intended User	Product developers at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The detailed purpose for our study is to compare a coated spherical roller bearing (232/530) to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Helene Berg - .
Reviewer	Olle Ramnäs -
Applicability	The data is valild for cutting of steel bars of the same material and dimensions and with the same processing equipment.
About Data	Data from the cutting process in Kode is obtained from the product manager in Kode and from Niclas Thim.
Notes	

SPINE LCI dataset: CuZn37 casting and drawing to wire

Administrative	
Finished	Y
Date Completed	1995
Copyright	Metall/ Berlin Metall Verla 1947-
Availability	Full availability

Technical System	
Name	CuZn37 casting and drawing to wire
Functional Unit	1 kg CuZn37 wire
Functional Unit Explanation	
Process Type	Gate to gate
Site	Germany
Sector	Materials and components
Owner	Germany
Technical system description	Pure metal is transported, melted in an induction furnace, alloying elements are added and the alloy is cast semi continually into bars. The round bars are heated to 700-750C and pre-pressed to 10 mm wire indirectly through Merloch matrixes. The wire is then pickled and pre-drawn. After an anneal at 520C it is pickled again, treated and drawn to the final thickness of 3mm. After a final anneal the material is delivered. Coppercontaining sludge is a byproduct. 0.43 kg per kg product is recycled (0.14 in the melting and casting process and 0.29 kg in the forming process).

	Technology --
Intended User	Life cycle assessments
General Purpose	Increase knowledge about environmental impacts from copper industry
Detailed Purpose	Supply specialists in the field with data for life cycle assessments
Commissioner	- Deutsche Kupfer-Institut Dusseldorf, Wirtshaftsvereinigung Metall e. V. and various industrial companies.
Practitioner	- Institut fur Metallhuttenwesen und Elektrometallurgie der RWTH, Aachen Germany .
Reviewer	- None
Applicability	Can be used for western industrial countries. Best available technology in western Germany.
About Data	
Notes	If a cradle to gate process is to be calculated data for primary (data set ''High purity copper production from primary raw materials'') or secondary (data set ''High purity copper production from secondary raw materials'') production must be added to the present data. If using primary material data for ore mining and concentration (data set ''Copper ore mining and concentration'') also has to be added. For the primary production of pure copper products 0.57 of the values for ore mining and concentration should be added which for energy is 20MJ/kg. This because the emissions and energy use are expressed per kg copper in concentrate and the copper content is assumed to be 30 weight%. To this the energy for primary production of pure metal 21.8 MJ/kg copper must be added. For secondary production no energy for concentration and mining is used but 20.55 MJ/kg copper is to be added. For alloys additional energy has to be included for the manufacturing of the additives. A CuZn37 alloy consists of 63 w% Cu and 37w% Zn. This means that 0.63 of the primary energy for the above primary or secondary copper process has to be added (primary:26.3 MJ, secondary:12.9 MJ). The energy for production of zink 70 MJ/kg. In total this means adding 25.9 MJ for the zink. In total the primary energy to be added to cover the cradle to gate process is 52.2 MJ/kg CuZn37 for primary production and 38.8 MJ/kg CuZn37 for secondary production (alloying element still primary production only copper secondary). The same procedure can be used to add emissions and other information for the production of alloys.

SPINE LCI dataset: CuZn37 continuous casting

Administrative	
Finished	Y
Date Completed	1995
Copyright	Metall/ Berlin Metall Verla 1947-
Availability	Full availability

Technical System	
Name	CuZn37 continuous casting
Functional Unit	1 kg cast CuZn37
Functional Unit Explanation	
Process Type	Gate to gate
Site	Germany
Sector	Materials and components
Owner	Germany
Technical system description	Pure metal is transported, melted in an induction furnace, alloying elements are added and the alloy is cast continually into slabs. Slags and dust are byproducts.

Notes	For production of kokille CuZn37Pb pure metals and block metal are added in not given proportions. Energies and emissions for producing those have to be included when making a cradle to gate assessment.

SPINE LCI dataset: CuZn39Pb2 casting and pressing to rods

Administrative

Finished	Y

Date Completed	1995
Copyright	Metall/ Berlin Metall Verla 1947-
Availability	Full availability

Technical System

Name	CuZn39Pb2 casting and pressing to rods
Functional Unit	1 kg CuZn39Pb2 bars
Functional Unit Explanation	
Process Type	Gate to gate
Site	Germany
Sector	Materials and components
Owner	Germany
Technical system description	Pure metal is transported, melted in an induction furnace, alloying elements are added and the alloy is cast semi continually into bars. After heating the round bars to 700C most often the bars are pressed indirectly througn Merloch matrixes to 19 mm hexagon bars. These bars are then pickled and drawn to the final size of 17mm. Anneals in between and at the end might be necessary. Coppercontaining sludge is a byproduct. 0.5 kg per kg product is recycled (0.14 in the melting and casting process and 0.36 kg in the forming process).

Notes	The total primary energy required for transporting, melting, casting and forming CuZn39Pb2 by drawing to bars is 9.4-11.6 MJ/kg product. Of this energy 4.8 is associated with the melting and casting and 4.6-6.8 with the forming processes. The higher forming value is for a smaller bar size.The energy values also take the recyclate into consideration. An additional 0.4 MJ/kg has to be added for transport of additives and 0.1MJ/kg for transports within the company. A German electricity mix is used and described (in wastes and emissions) as well as the energy from fossil sources. Values in terms of MJ/km for different transports are given with the specific emissions connected to them. The energy use for a number of help materials is included.

About Inventory	
Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -
Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998
About Data	
Notes	

SPINE LCI dataset: Delivery van, distribution, diesel

Administrative	
Finished	Y
Date Completed	1998 - 08
Copyright	NTM
Availability	Public

Technical System	
Name	Delivery van, distribution, diesel
Functional Unit	1 tonkm, 50 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 50 %. An utilisation level of 50 % is considered to be representative for Swedish domestic distribution traffic if *empty trips are not included.*
Process Type	Gate to gate
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of delivery van for distribution, approximately 5.5 m long with a curb weight of 3.5 tons and a maximum loading capacity by weight of 1.4 tons. Fuel: diesel, MK 1 (sulphurous content: 2 ppm). Fuel consumption: 1.8 l/10km. Utilisation level: 50% by weight. The data represents vans constructed before 1996 and mixed driving (urban and highway) and includes cold starts and aging effects.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO_2 -tax regulated CO_2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	Data are valid for vans constructed before 1996.
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic. Empty trips are not included. *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests .
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1998 - 08
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission data presented by Swedish Hauliers Assosiation in cooperation with ASG, BTL and ''Nordisk Transport''. The basis for the data originates from IVL (reference not stated by NTM). The utilisation level (loading factor) is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic. The utilisation level is based on the load carrying weight, i.e. the weight on which the customer price is based. This means that bulky cargo is multiplied with a factor in order to compensate for taking up volume. The average break-point density is 275 kg/m3. Energy use and emissions per tonkm with a truck should be based on the load carrying weight. The emissions were calculated using emission factors, together with assumptions on the fuel consumption, type of fuel used and utilisation level. (g/vkm) Petrol Diesel NOx: 0.10 0.50 HC: 0.20 0.15 CO: 1.50 0.50 PM: 0.005 0.10 Fuel cons. 2.8 l/10km 1.8 l/10km The quantity value for the energy use refer to average fuel consumption. The emissions of CO2 and SO2 is based on the fuel consumption.
Literature Reference	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8, page II.300.
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred.

About Inventory

Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation)

	The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	Björkman, Mikael - BTL 412 97 Göteborg .
Reviewer	None, to be reviewed. -
Applicability	The data should not be used for any detailed study of transport systems. More detailed information is needed in order to carry out such studies, e.g. regarding the vehicle -type -age and performance, fuel type, the nature of the goods, the utilisation level etc. For a specific transport, the company carrying out the transport should be contacted in order to get information on how the goods are handled and how the transport is carried out. Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred. ***Handling of goods*** The data presented by NTM is representative for a terminal based transport system. The vehicles can be used in different ways, primarily altering the degree of utilisation. Several other types of road based cargo transport systems is not well described by the data (e.g. oil and excavated materials) Terminal based road transports generally consists of 1-3 parts: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles while the inter-terminal traffic is operated by larger units, typically with a higher degree of utilisation. *--Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a trailer at the terminal for further transport. *--General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited *--Parcel goods (<100 kg)* are normally handled in small vehicles ***The following vehicles and equipages are used in terminal based transport systems in Sweden:*** *--Parcel truck/van, max 3,5 tonnes* is mainly used for transportation of parcels. *--Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic. *--Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic. *--Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods. *--Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland. *--Truck with semi-trailer, max 42 tonnes* is used for international long-distance traffic. ***Utilisation level*** The data is only applicable for an utilisation level of 70 % for long distance transport and 50 % for local distribution and regional transport, which is considered representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip, due to specialised vehicles). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than smaller firms of haulage. The utilisation of company internal vehicles is generally low. The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden): -excavated materials and round timber - 50% -manufactured products (wholesale goods) - slightly more than 20% -provisions and animal forage - approx. 15% -mixed cargo (general goods) approx - 10 %. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***Fuel***

	The fuel used is diesel environmental class 1, except for petrol driven delivery vans who are assumed to use standard unleaded petrol. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (> 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions. Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the data. NGM propose that data from Blinge et. al (Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997) should be used. This study is based on best available technology and Swedish conditions which is likely to yield a low figure. ***International road transports*** The data may be used for international transport if the data is recalculated for diesel environmental class 3. This will alter both the SOx emission and the regulated engine emissions. Generally the fleets in western Europe is composed of newer vehicles than in Sweden. The utilisation of the vehicles may also vary in different countries.
About Data	The data for emissions is based on emission factors. The origin of the emission factors is not specified. This means that several parameters that influence the energy use and emissions in regular traffic are probably not considered, e.g. climate, topography, driving technique, maintenance etc. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. Data for vans differs from other trucks as emission data includes effects due to cold starts, aging effects and operations on different road tyes. (a mix of urban and highway traffic)
Notes	The person stated as ''Practitioner'' is the contact person for the data for truck transportation in NTM. The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: Delivery van, distribution, petrol

Administrative	
Finished	Y
Date Completed	1998 - 08
Copyright	NTM
Availability	Public

Technical System	
Name	Delivery van, distribution, petrol
Functional Unit	1 tonkm, 50 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 50 %. An utilisation level of 50 % is considered to be representative for Swedish domestic distribution traffic if *empty trips are not included.*
Process Type	Gate to gate
Site	Sweden
Sector	Land transport
Owner	Sweden

Technical system description	Operation of delivery van for distribution, approximately 5.5 m long with a curb weight of 3.5 tons and a maximum loading capacity by weight of 1.4 tons. Fuel: petrol (sulphurous content: 180 ppm). Fuel consumption: 2.8 l/10km. Utilisation level: 50% by weight. The data represents vans constructed before 1996 and mixed driving (urban and highway) and includes cold starts and aging effects.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	Data are valid for vans constructed before 1996.
Geographical Boundary	Data is based on Swedish conditions.
Other Boundaries	The utilisation level is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic. Empty trips are not included. *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the vehicle *Excluded subsystems* -Exhaust emission control -Precombustion, i.e. production and distribution of the fuel -Maintenance of the vehicle -Erection and operation of infrastructure -After-treatment of the vehicle -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1998 - 08
Data Type	Derived, unspecified
Represents	NTM
Method	The emissions were calculated using emission data presented by Swedish Hauliers Assosiation in cooperation with ASG, BTL and ''Nordisk Transport''. The basis for the data originates from IVL (reference not stated by NTM). The utilisation level (loading factor) is assumed to be 50% for delivery vans and medium-sized lorries in local distribution traffic. The utilisation level is based on the load carrying weight, i.e. the weight on which the customer price is based. This means that bulky cargo is multiplied with a factor in order to compensate for taking up volume. The average break-point density is 275 kg/m3. Energy use and emissions per tonkm with a truck should be based on the load carrying weight. The emissions were calculated using emission factors, together with assumptions on the fuel consumption, type of fuel used and utilisation level. (g/vkm) Petrol Diesel NOx: 0.10 0.50 HC: 0.20 0.15 CO: 1.50 0.50 PM: 0.005 0.10 Fuel cons. 2.8 l/10km 1.8 l/10km The quantity value for the energy use refer to average fuel consumption. The emissions of CO2 and SO2 is based on the fuel consumption.
Literature Reference	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8, page II.300.
Notes	Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred.

About Inventory	
Publication	www.ntm.a.se Data documented by: Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	Björkman, Mikael - BTL 412 97 Göteborg .
Reviewer	None, to be reviewed. -
Applicability	The data should not be used for any detailed study of transport systems. More detailed information is needed in order to carry out such studies, e.g. regarding the vehicle -type -age and performance, fuel type, the nature of the goods, the utilisation level etc. For a specific transport, the company carrying out the transport should be contacted in order to get information on how the goods are handled and how the transport is carried out. Calculating the environmental impact in relation to transport work and utilisation level is most appropriate if a calculation over a longer period of time (e.g. a year) is needed, e.g. in a transport contract. In such a case, different types of vehicles and utilisation levels may have occurred. ***Handling of goods*** The data presented by NTM is representative for a terminal based transport system. The vehicles can be used in different ways, primarily altering the degree of utilisation. Several other types of road based cargo transport systems is not well described by the data (e.g. oil and excavated materials) Terminal based road transports generally consists of 1-3 parts: 1. Collection of the goods to terminal 2. Long-distance transport between terminals 3. Distribution of the goods from terminal The collection and distribution routes are generally performed by smaller vehicles while the inter-terminal traffic is operated by larger units, typically with a higher degree of utilisation. *--Wholesale goods (>1000 kg)* are generally not handled via terminal. The goods is collected by a truck and driven straight to the customer. The truck may however collect a

trailer at the terminal for further transport.
--*General goods (100-1000 kg)* are generally handled via terminal. The goods may be both weight and volume limited
--*Parcel goods (<100 kg)* are normally handled in small vehicles

The following vehicles and equipages are used in terminal based transport systems in Sweden:
--*Parcel truck/van, max 3,5 tonnes* is mainly used for transportation of parcels.
--*Light truck, max 8 tonnes* is used for local distribution, mainly in city traffic.
--*Truck, max 18 tonnes* is used for district distribution and local distribution in city traffic.
--*Truck, max 24 tonnes* is mainly used for transportation of general (styckegods) and wholesale (partigods) goods.
--*Heavy truck with trailer, max 60 tonnes* is used for long distance transports. The towcar for the equipage is a truck, max 24 tonnes. The vehicle is not permitted in the EU and is *only used for Swedish domestic long-distance transport.* The vehicle is also permitted in Finland.
--*Truck with semi-trailer, max 42 tonnes* is used for international long-distance traffic.

Utilisation level
The data is only applicable for an utilisation level of 70 % for long distance transport and 50 % for local distribution and regional transport, which is considered representative for Swedish transports according to the Swedish Road Haulage Association and the firms of haulage that has participated in the work. It should however be noted that the average utilisation level might vary between different types of goods and firms of haulage. There are however no general rules on how to assess the utilisation level for a specific transport. There are some types of goods (e.g. timber and chemicals) that generally have an utilisation level of 50 % (i.e. full load one way and empty return trip, due to specialised vehicles). There may also be regional differences. The major shipping agents may be assumed to have a higher utilisation level than smaller firms of haulage. The utilisation of company internal vehicles is generally low.

The utilisation level includes both weight and volume limited goods, but *not empty trips*. During 1996 24 % of all transports were empty transports. Most of the empty transports (90%) were performed on distances shorter than 100 km. The share of empty trips for different types of goods during 1996 were according to SCB (Statistics Sweden):
-excavated materials and round timber - 50%
-manufactured products (wholesale goods) - slightly more than 20%
-provisions and animal forage - approx. 15%
-mixed cargo (general goods) approx - 10 %.

Bulky goods
The data may be used for bulky goods by recalculation of the volume to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.

Fuel
The fuel used is diesel environmental class 1, except for petrol driven delivery vans who are assumed to use standard unleaded petrol. According to the Swedish Petroleum Institute, the major part of all diesel fuel oil sold at present time is of class 1 (> 85% at June 1996). Class 1 diesel oil has the lowest aromatic carbon and nitrogen content of all diesel oil sold in Sweden, resulting in lower particle, carbonhydrate and NOx emissions.

Precombustion, i.e. extraction, refining and distribution of the fuel are not included in the data. NGM propose that data from Blinge et. al (Arnäs, P-O, Blinge, M., Bäckström, S., Furnander, Å. ''Livscykelanalys av drivmedel - En studie med utgångspunkt från svenska förhållanden och bästa tillgängliga teknik'', Meddelande 95, Department of Transportation and Logistics, Chalmers University of Technology, 1997) should be used. This study is based on best available technology and Swedish conditions which is likely to yield a low figure.

International road transports
The data may be used for international transport if the data is recalculated for diesel environmental class 3. This will alter both the SOx emission and the regulated engine emissions. Generally the fleets in western Europe is composed of newer vehicles than in Sweden. The utilisation of the vehicles may also vary in different countries.

About Data

The data for emissions is based on emission factors. The origin of the emission factors is not specified. This means that several parameters that influence the energy use and emissions in regular traffic are probably not considered, e.g. climate, topography, driving technique, maintenance etc. Since exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially.

Data for vans differs from other trucks as emission data includes effects due to cold starts, aging effects and operations on different road tyes. (a mix of urban and highway traffic)

Notes

The person stated as ''Practitioner'' is the contact person for the data for truck transportation in NTM.
The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation.

	The major Swedish actors in the transportation business, which are members of NTM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for NTM is Anna Hadenius, TFK - Transport Research Institute, Stockholm.

SPINE LCI dataset: De-watering of water-sludge

Administrative	
Finished	Y
Date Completed	1999-04-19
Copyright	
Availability	public

Technical System	
Name	De-watering of water-sludge
Functional Unit	1 m3 of recieved water-sludge from Reci Industri Halmstad.
Functional Unit Explanation	Water-sludge is delivered to the facility by truck from Reci Halmstad. The water-sludge is a waste product from the biological treatment of of the oil-contaminated water at Reci Halmstad.
Process Type	Gate to gate
Site	Reci Industri AB Box 48047 418 21 Göteborg
Sector	Waste treatment
Owner	Reci Industri AB Box 48047 418 21 Göteborg

Technical system description	Water-sludge arrives from Reci Halmstad by truck to Reci's facility at Skarvik, Göteborg. In the de-watering facility waste is separated into a solid phase and a liquid phase. The solid phase, mostly containing of sediment from oil-separators and sand, are deposited at Torsviken. The water phase is led to the water treatment facility at Reci Industri Göteborg, Cicelan (Not part of the studied system). The waste treated at the de-watering facility contains sludge 11 000 tonnes / year, liquid industrial waste 12 000 tonnes / year and oil sludge 3000 tonnes / year. A decription about the water treatment facility is found in the SPINE report ''Treatment of oil-contaminated waste water''

System Boundaries

Nature Boundary	Other impacts then the landfill caused by the solid phase are not calculated. Resources that are not seen as limited in Sweden are neglected e.g. land usage and fresh water. · The electricity utilised by the system is only seen as a resource and the origin is not interpreted.
Time Boundary	The study only deals with retrospective data and no attempts are made to predict future events or conditions. 1997 is assumed as a suitable time frame to collect and interpret data.
Geographical Boundary	The geographical boundary for the converting of waste-oil is set to Sweden.
Other Boundaries	The environmental impact from capital goods and activities serving the process are neglected e.g. personell, infrastructure and facilities. Moreover, maintenance and wear down of the system are neglected as well. · No resource use or impacts from Reci Göteborg is allocated to the de-watering of water-sludge. It is today impossible to say how much the de-watering facility contributes with as no measurements have been made. The treatment of water-sludge from Reci Halmstad is in its turn only a smaller part of the total amount de-watered at the facility (501 m3 of totally 26 000 m3). · The amount of pollutants in the water- and the solid-phase are not known. But if they where to be measured the contribution from water-sludge should be calculated with the data about the water-sludge contents in mind. The pollutants are supposed to be adsorbed in the solid-phase deposited at Torsviken. · As the energy consumption is not known and is supposed to be minor no energy use is loaded upon the de-watering of water-sludge. · No spill occurs in the plants. · The loading and unloading step is neglected in terms of consuming resources or emitting outputs.

About Inventory

Publication	Master thesis: ''LCA on converted fuel oil'' by Daniel Strandberg and Christer Wik, MSc students Technical environmental planning, Chalmers Univeristy of Technology -- Data documented by: Daniel Strandberg and Christer Wik, MSc students, Technical Environmental Planning, Chalmers University of Technology Documentation reviewed and classified by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology --
Intended User	Internal use at Reci Industri
General Purpose	The objective of this study was to carry out a Life Cycle Assessment for converted fuel oil. The analysis involves outlining the environmental hazardous steps in the production. The result will be used internally to aid as an environmental improving guidance as well as to receive a better view of the process. Externally the result is a part of Reci's ISO 14000 certification, which acts as a guarantee to the customers. The quality of the inquiry is set due to the standards of a Master of Science thesis.
Detailed Purpose	To estimate the resource use and emissions from de-watering of water-sludge from Reci Halmstad.
Commissioner	Schaff, Lars, environmental manager - Reci Industri AB Box 48047 418 21 Göteborg Sweden.
Practitioner	Strandberg, Daniel and Christer Wik - MSc students Technical Environmental Planning Chalmers University of Technology 41296 Göteborg Sweden.
Reviewer	Beckman, Torsten - Technical environmental planning Chalmers University of Technology 412 96 Göteborg Sweden
Applicability	The data are specific for de-watering of water-sludge from Reci Halmstad.
About Data	· The water-sludge often varies much in its contents. The calculation is performed based on an average value of the data presented for the water-sludge. The data is received from analysing the water-sludge at Reci Halmstad. The percentage of dry substance in the water sludge is based on an average value 15 per cent. This gives that 15 per cent of the water sludge will end up as a solid phase and the rest as water. Mass-balance · As the emissions or pollutants in the water is unknown the mass balance follows the simple assumption above, that 15 per cent becomes sediment and the rest water.
Notes	The reviewer acted as supervisor for the Master thesis: ''LCA on converted fuel oil''

SPINE LCI dataset: Diesel combustion

Technical System	
Name	Diesel combustion
Functional Unit	MJ
Functional Unit Explanation	Per MJ energy generated from combustion of diesel in a vehicles engine.
Process Type	Gate to gate
Site	Sweden
Sector	Fuel
Owner	Sweden
Technical system description	Diesel combustion is a gate-to-gate scenario using diesel fuel (treated separately in another activity) to generate energy to put a vehicle in motion.

System Boundaries	
Nature Boundary	Emissions to air from combustion of the fuel are included. Other impacts from the operation of the vehicle are not included.
Time Boundary	The data describes the situation prior to 1991.
Geographical Boundary	N/A
Other Boundaries	N/A
Allocations	N/A
Systems Expansions	The system does not include the production of the diesel fuel.

Flow Data	
General Activity QMetaData	
Date Conceived	1991-01-01
Data Type	Unspecified
Represents	NTM
Method	Emissions caused by combustion of diesel fuel in vheicle engins
Literature Reference	A-M Tillman et al. Packaging and the environment, SOU 1991:77, Chalmers Industriteknik, Göteborg, Sweden.
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

SPINE LCI dataset: Diesel driven freight train, future

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Diesel driven freight train, future
Functional Unit	1 tonkm, 55 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 55 %. An utilisation level of 55 % is representative for Swedish domestic traffic if *transportation of empty trucks are included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport

Owner	Sweden
Technical system description	Operation i.e. propulsion of a freight train with a diesel-driven engine. The locomotive engine represents best available technology, not yet in use. Engines originally developed for trucks are assumed to be installed in the locomotive engine. Maximum gross weight of the train: 1200 tonnes. Maximum available loading capacity with regard to weight 972 tonnes.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents best available technology in 1997.
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 55 %. The utilsation level includes transportation of empty trucks. *Parameters not considered* -Driving technique -External conditions i.e. road conditions, climate etc. -Maintenance level of the engine -Use of lubricating oil -Wear of brake lining, rail and wheel *Excluded subsystems* -Precombustion, i.e. production and distribution of the fuel. -Maintenance of the engine -Erection and maintenance of infrastructure -After-treatment of the engine -Handling of production rests
Allocations	N/A
Systems Expansions	N/A

About Inventory	
Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Ingela Melkersson, SJ Stab Information, contact person for rail transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Trouve, Johan - SJ (Swedish State Railways), Stab Information, Box 1522, 401 50 Göteborg.
Reviewer	
Applicability	The ambition with the data was to get a picture of future energy use and emissions for Swedish train traffic. The data represents best available technology not yet in use.
About Data	The data is based on tests on performed in a laboratory according to a new test cycle (proposed for standardisation). This means that several parameters that influence the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Since the exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. ***Utilisation level*** The average utilisation level for diesel-driven trains (55%) are higher than for electrically driven trains, inter alia because the trains generally runs shorter distances. The average utilisation level includes transportation of empty trucks and was based on statistics from 1993 from the Swedish State Railways. Today the average utilisation level is higher according to the Swedish State Railways due to different actions to use the trains more effectively. The utilisation level for a specific transport may vary. There are however no general rules regarding differences in the utilisation level, and what utilisation level to chose for a specific transport operation.
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives.

	The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

Reviewer	
Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to obtain information on how the goods are handled and the transport is carried out. Railway traffic generally handles transportation of large heavy goods over long distances. Both electrically driven and diesel driven trains may be used: *Electrically driven freight trains* transport 95 % of the goods handled by train. Each truck of the trains may be assumed to have a loading capacity with regard to weight of 55 tonnes and a maximum gross weight of 80 tonnes. The trains are normally marshalled. *Electrically driven combi train* consists of trucks loaded with load carriers that also may be loaded and transported by truck. The share of goods transportation by combi train is about 5 % of the total transportation by electrically driven goods trains. *Electrically driven system trains* are not recoupled on the way and always take the same route between two addresses. No marshalling is done, but a diesel engine may be used at the end points. The trains are generally fully loaded one way, and empty on the return trip, i.e. the utilisation level is 50% or higher. System trains ordinarily runs special transportation assignments for different types of industry. *Diesel driven engines* (T44) are mainly used for shunting and for regular traffic in sections where there is no aerial line. There are still some sections of the Swedish railway system that are not electrified. SJ also uses a smaller diesel driven engine (V5) for shunting. The V5 engine has a capacity of 450-500 tonnes gross weight and is not ordinarily used for regular traffic. ***Marshalling*** The major part of the goods is marshalled at 6 main junctions were the goods are gathered and new trains are put together for new destinations. Shunting is generally done by diesel driven engines and is performed in two ways: -Hump shunting (vallväxling) -Fly shunting (planväxling) ***Distance*** The railway network and the fact that the goods generally are marshalled means that the goods not always travel the shortest route between two destinations. When using the data, the distance may thus be difficult to assess. The company carrying out the transport should be contacted to get an accurate estimate of the distance. SJ (Swedish State Railways) has developed environmental data software with a database of distances between 70 different places, considering the infrastructure. The database does however not give information on which lines that are not electrified. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume of the goods to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.
About Data	***Test cycle*** The data is based on tests on one locomotive engine performed in a laboratory according to a standardised test cycle (ECE R49). This means that several parameters that influence the energy use and emissions in regular traffic are not considered, e.g. climate, topography, driving technique, maintenance etc. Since the exhaust emissions depend on the engine speed and load conditions, the emissions in actual operation may vary substantially. The test cycle was developed to represent long-distance traffic. ***Utilisation level*** The data is based on an average utilisation level of 55% (including transportation of empty trucks). The average utilisation level was based on statistics from 1993 from the Swedish State Railways. Today, the average utilisation level is higher according to the Swedish State Railways due to different actions to use the trains more effectively, and it is not possible to discern a difference in utilisation between electrically driven and diesel driven freight trains.
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at

	the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

Functional Unit	1 MJ
Functional Unit Explanation	1 MJ output of diesel EN590, EU-15
Process Type	Cradle to gate
Site	
Sector	Fuel
Owner	
Technical system description	There are two data sources for diesel production, which have been considered to be the best available data to be published in the f3 project; data from an LCA for diesel produced in Sweden (Öman 2011) and data from the ELCD database. For Swedish MK1 diesel the data from Öman 2011 have been chosen and for the diesel according to the EN590 standard, the ELCD data were applied. When looking at the GWP for instance, the data applied for MK1 is 27 % lower than the ELCD data applied for EN590. This data set describes a mass-weighted average refinery for Europe. The data set considers the whole supply chain from exploration over crude oil extraction to transport to refinery. The background system is addressed as follows: Electricity, Thermal energy: The electricity (and thermal energy as by-product) used is modelled according to the individual country-specific situation. The country-specific modelling is achieved on multiple levels. Firstly the individual power plants in service are modelled according to the current national grid. This includes net losses and imported electricity. Second, the national emission and efficiency standards of the power plants are modelled. Third, the country-specific fuel supply (share of resources used, by import and / or domestic supply) including the country-specific properties (e.g. element and energy contents) are accounted for. Fourth, the import, transport, mining and exploration processes for the energy carrier supply chain are modelled according to the specific situation of each power-producing country. The different mining and exploration techniques (emissions and efficiencies) in the different exploration countries are accounted for according to current engineering knowledge and information. Steam: The steam supply is modelled according to the individual country-specific situation with regard to the technology efficiencies and energy carriers used. Efficiencies range from 84% to 94% in relation to the representative energy carrier (gas, oil, coal). Coal, crude oil and natural gas used for the generation of steam are modelled according to the specific import situation.

System Boundaries	
Nature Boundary	
Time Boundary	2010 - 2013
Geographical Boundary	Europe (EU15 average)

Other Boundaries	
Allocations	For the combined crude oil, natural gas and natural gas liquids production allocation by net calorific value is applied. For all products of the refinery, allocation by mass and net calorific value is applied. The manufacturing route of every refinery product is modelled and so the effort of the production of these products is calculated specifically. Two allocation rules are applied: The raw-material (crude oil) consumption of the respective stages, which is necessary for the production of a product or an intermediate product, is allocated by energy (mass of the product * calorific value of the product). In these way products with high caloric values, e.g. gasoline or gases are assigned to higher raw material consumption and so higher environmental impacts compared with low caloric value products (e.g. asphalt, residual oil). The energy consumption (thermal energy, steam, electricity) of a process, e.g. atmospheric distillation, being required by a product or a intermediate product, are charged on the product according to the share of the throughput of the stage (mass allocation). The products, which are more complex to produce and therefore pass a lot of refinery facilities e.g. gasoline, are assigned with a higher energy consumption (and so higher emissions) compared with e.g. straight run products.
Systems Expansions	No.

About Inventory

Publication	Hallberg et al, (2013) "Setup of f3 data network for Well-to-wheel (method and) LCI data for fossil and renewable fuels in the Swedish market", f3 - Swedish Knowledge Centre for Renewable Transportation Fuels, f3 project report, Available at www.f3centre.se
Intended User	LCA practitioner
General Purpose	To provide and publish best available LCI data on vehicle biofuels and fossil fuels well to tank and tank to wheel relevant for the Swedish market.
Detailed Purpose	
Commissioner	- f3 - The Swedish Knowledge Centre for Renewable Transportation Fuels.
Practitioner	- Felipe Oliveria, IVL.
Reviewer	- Lisa Hallberg, IVL
Applicability	
About Data	This dataset is the part of the results from the f3 project "Setup of f3 data network for Well-to-wheel (Method and) LCI data for fossil and renewable fuels in the Swedish market". Further details about this project can be found in the project report.

Notes	The original data were provided per kg and have been recalculated to per MJ fuel using a heat value of 42.6 MJ/kg (4). This heat value corresponds to diesel according to the EN590 standard. The original ELCD documentation is much more extensive than the documentation in the f3 project. The most important parts were included.

SPINE LCI dataset: Diesel engine, Euro 0

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Diesel engine, Euro 0
Functional Unit	kWh
Functional Unit Explanation	1 kWh mechanical work done by the engine
Process Type	Unit operation
Site	Sweden
Sector	Machinery and equipment
Owner	Sweden
Technical system description	Operation of a diesel engine, Euro 0, manufactured before 92 when environmental standards on emissions from diesel engines were not yet implemented.

System Boundaries	
Nature Boundary	Regulated emissions to air have been considered.
Time Boundary	The aim was that the data should represent engines manufactured before 1992, when there were no environmental standards for the emissions from diesel engines.
Geographical Boundary	The aim was that the data would represent engines manufactured in Sweden.
Other Boundaries	A specific test cycle on the engine (ECE R49) was used.
Allocations	N/A
Systems Expansions	N/A

Flow Data	
General Activity QMetaData	
Date Conceived	1997-01-01
Data Type	Unspecified, expert outspoke
Represents	NTM
Method	The emissions were obtained by the ECE R49 test cycle. The energy use is based on assumptions on the efficiency of the engine. The fuel was assumed to be diesel environmental class 1. See specific QMetaData for each flow. Method description for NOx, HC, particles and CO can be found under NOx The quantity value for the fuel consumption refer to average efficiency of the engine, the maximum and minimum value refer to changes in the efficiency of the engine due to degeneration. The emissions of CO2 and SO2 is based on the fuel consumption. For emissions of NOx, HC, particles and CO, the quantity

	value refer to an average engine guaranteed by Volvo Truck Corporation and the maximum value refer to voluntary European emission regulations for diesel engines before 1992.
Literature Reference	The data set is published in the ELCD database (1). The practitioner of the LCA is PE International (2) on behalf of JRC (3). (1) http://lca.jrc.ec.europa.eu/lcainfohub /datasetDownload.vm (2) PE International GmbH, Leinfelden-Echterdingen, Germany (the developer of the Gabi software and databases). (3) European Commission, Joint Research Centre (JRC), Institute for Environment and Sustainability (IES). (4) SBPI, http://spbi.se /blog/faktadatabas/artiklar/berakningsmodeller/
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

Flow Table and Specific Meta Data

QMetaData	***Direction***	***FlowType***	***Substance***	***Quantity***	***Min***	***Max***	***Unit***	***Environment***	***Geography***
Date concieved: 1997-01-01 Data type: Unspecified, expert outspoke Method: The fuel consumption is based on the efficiency of the engine. The quantity value refer to an average engine. The minimum and maximum value is based on assumptions on changes in the efficiency of the engine due to degeneration. **The following data was used in the calculations:** *Average efficiency of the engine:* 39 % *Change of efficiency of the engine due to degeneration:* -minimum value: 0,99 in relation to the average engine -maximum value:1,01 in relation to the average engine The average efficiency and the change of efficiency is based on assumptions *Data for the fuel, diesel environmental class 1:* Thermal value: 43,43 MJ/kg Density: 0,81 kg/l Sulphur content: 10 ppm The data was given by the Swedish Petroleum Institute.	Input	Refined resource	Diesel environmental class 1	213	211	215	g	Technosphere	
Method: See QMetaData for NOx	Output	Emission	CO	1.5		12	g	Air	
Date concieved: 1997-01-01 Data type: Unspecified, expert outspoke Method: The emission was calculated from the fuel consumption using the carbon content in the diesel. **The following data was used in the calculations:** *Data for the fuel, diesel environmental class 1:* Thermal value: 43,43 MJ/kg Density: 0,81 kg/l CO2 emission: 73 g/MJ fuel Sulphur content: 10 ppm The data was supplied by the Swedish Petroleum Institute.	Output	Emission	CO2	674	669	682	g	Air	
Method: See QMetaData for NOx	Output	Emission	HC	1.5		2.5	g	Air	
Date concieved: 1997-01-01 Data type: Derived, unspecified Method: The emissions were obtained by a standardised test cycle, ECE R49 on the engine. The quantity value refer to an average engine guaranteed by Volvo Truck Corporation, the maximum value refer to voluntary European emission regulations for diesel engines before 1992. No minimum value (except for NOx) was given. *The ECE R49 is a steady state cycle for heavy duty truck engines*. Consists of a sequence of 13 constant engine speed and load modes. Emissions are analysed for each test mode. Then the overall emission result is calculated as a (weighted) average from all test modes. The cycle is characterised by high	Output	Emission	NOx	11	9	14	g	Air	

average engine load and high exhaust gas temperature.									
Method: See QMetaData for NOx	Output	Emission	Particles	0.4			g	Air	
Date concieved: 1997-01-01 Data type: Unspecified, expert outspoke Method: The emission was calculated from the fuel consumption using the sulphur content in the diesel **The following data was used in the calculations:** *Data for the fuel, diesel environmental class 1:* Thermal value: 43,43 MJ/kg Density: 0,81 kg/l Sulphur content: 10 ppm The data was supplied by the Swedish Petroleum Institute. SPINE LCI dataset: Diesel engine, future

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Diesel engine, future
Functional Unit	1 kWh
Functional Unit Explanation	1 kWh mechanical work done by the engine.
Process Type	Unit operation
Site	Sweden
Sector	Machinery and equipment
Owner	Sweden
Technical system description	Operation of a diesel engine representing the proposed Euro 3 environmental standard.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are -regulated emissions for diesel engines: NOx, HC, particles and CO -fuel regulated: SO2 -tax regulated CO2.
Time Boundary	The aim was that the data should represent the best available technology, not yet in use (proposed Euro 3 environmental standard).
Geographical Boundary	The aim was that the data would represent engines manufactured in Sweden.
Other Boundaries	A specific test cycle was used. The test cycle is proposed for standardisation.
Allocations	N/A
Systems Expansions	N/A

Flow Data	
General Activity QMetaData	
Date Conceived	1996-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The data was obtained by tests performed on the engine by a new test cycle. The energy use is based on the efficiency of the engine. The fuel was assumed to be diesel environmental class 1. See specific QMetaData for each flow. Method description for NOx, HC, particles and CO can be found under NOx .
Literature Reference	The data set is published in the ELCD database (1). The practitioner of the LCA is PE International (2) on behalf of JRC (3). SPINE LCI dataset: Diesel MK1, cradle-to-gate, energy allocation - f3 fuels

Administrative	
Finished	Y
Date Completed	2013-11-30
Copyright	f3 - Swedish Knowledge Centre for Renewable Transportation Fuels
Availability	Public

Technical System	
Name	Diesel MK1, cradle-to-gate, energy allocation - f3 fuels
Functional Unit	1 MJ
Functional Unit Explanation	1 MJ output of diesel MK1
Process Type	Cradle to gate
Site	
Sector	Fuel
Owner	
Technical system description	There are two data sources for diesel production, which have been considered to be the best available data to be published in the f3 project; data from an LCA for diesel produced in Sweden (Öman 2011) and data from the ELCD database. For Swedish MK1 diesel the data from Öman 2011 have been chosen and for the diesel according to the EN590 standard, the ELCD data were applied. When looking at the GWP for instance, the data applied for MK1 is 27 % lower than the ELCD data applied for EN590. The study comprises, within its system boundary, the extraction of crude oil, transport from the extraction site to the refinery, production of petroleum products at the refinery, transport from the refinery to oil depots, storage at depots, as well as distribution from depots to customer/gas station, for 1 MJ of diesel. The LCI is based mostly on the conditions of the diesel designed to be sold in the Swedish market in 2009. For example, the crude oil used to produce this diesel is identified by its origin. Inputs and outputs in the refining process (amount of crude oil, electricity consumption and emissions) have been allocated according the energy content of products and calculated as an average of three refineries (of a total of 6), which provide the Swedish market with diesel. The study also includes the mapping of the distribution of diesel through different means of transport, from refinery to depot/customer, for the six refineries mentioned above. The electricity consumed during the life cycle (refining process, at storage, railroad transportation) is assumed to be based on the Swedish electricity mix in a supply perspective, i.e. the environmental impacts are calculated based on the consumed electricity, not produced.

System Boundaries	
Nature Boundary	
Time Boundary	2010 - 2013
Geographical Boundary	Sweden
Other Boundaries	
Allocations	Inputs and outputs in the refining process (amount of crude oil, electricity consumption and emissions) have been allocated according the energy content of products.
Systems Expansions	No.

Technical System	
Name	Diesel production
Functional Unit	MJ
Functional Unit Explanation	Per MJ diesel fuel ready for combustion in an engine.
Process Type	Cradle to gate
Site	North Sea
Sector	Fuel
Owner	North Sea
Technical system description	The data include emissions from energy use as well as specific process emissions for crude oil extracted in the North Sea.. The emissions from extraction, transport and refining of the raw energy carrier natural gas are not included.

System Boundaries

Nature Boundary	Emissions to air and water from the activities producing diesel fuel from crude oil are included (extraction, transport & refining). Emissions caused by the use of crude natural gas are neglected.
Time Boundary	All data refer to 1992.
Geographical Boundary	The crude oil is taken from the North Sea. Where it is transported to and where the refining takes place is not stated in the source.
Other Boundaries	N/A
Allocations	N/A
Systems Expansions	N/A

About Inventory

Publication	Birgit Backlund et al. Use of agro fibre for paper production from an environmental point of view, Nordpap DP 2/54, Scan forskrapport 682, oktober 1997. --- Data documented by: Göran Swan, Ola Svending, STORA Corporate Research Documentation reviewed by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology ---
Intended User	LCA practitioners
General Purpose	The purpose is to supply with LCA-data for diesel fuels used in forestry to be a part of further studies of wood products.
Detailed Purpose	These data were published in ''Use of agro fibre for paper production from an environmental point of view, Backlung et al. Nordpap DP 2/54 Scan Forskrapport, 1997''.
Commissioner	
Practitioner	Person, Lisa - Chalmers Industri Teknik .
Reviewer	

Applicability	This activity generates diesel fuel from mainly crude oil. It´s emissions origin from extraction, transport and refining. The product (diesel fuel) must be put in to another activity, where the fuel is combusted, generating energy.
About Data	
Notes	

SPINE LCI dataset: Diesel propulsed train

Administrative	
Finished	Y
Date Completed	1999 - 11
Copyright	NTM
Availability	The data is publically available.

Technical System	
Name	Diesel propulsed train
Functional Unit	1 tonkm , 55 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 55 %. An utilisation level of 55 % is representative for Swedish domestic traffic if transportation of empty waggons etc. are included.
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation i.e. propultion of freight train with a diesel-driven T44 engine. Diesel engines are mainly used for shunting and regular traffic in sections where there is no areal line. Maximum gross weight of the train: 1200 tonnes. Maximum available loading capacity with regard to weight 972 tonnes.

System Boundaries	
Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: - Regulated emissions for diesel engines: NOx, HC, particles and CO - Fuel regulated: SO2 - Tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data are representative for diesel powered trains in use 1999.
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 55 %. The utilisation level includes transportation of empty waggons and cars. Not included in the system Production and maintenence of the tracks. Driving technique External conditions, i.e., road conditions, climate etc. Maintenance level of the engine
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1999 - 06
Data Type	Random samples
Represents	NTM
Method	The emissions were calculated using emission factors obtained by the ECE R49 test cycle, together with the assumptions on the fuel consumption, type of fuel used (diesel environmental class 1) and utilisation level (55%). The emissions per tonkm were calculated using emission factors (g/kWh) obtained by a standardised test cycle, ECE R49 on the engine, where kWh refers to mechanical work done by the engine. The tests was performed by Motortestcenter. ***The following data was used in the calculations:*** *Assumptions given by the Swedish State Railways:* -Average fuel consumption: 3,5 l/km. -Utilisation level: 55 %, of the available loading capacity with regard to weight. *Data for the fuel, diesel environmental class 3 (given by the Swedish Petroleum Institute):* -Thermal value: 9,952 kWh/l -Density: 0,820-0,860 kg/l -Sulphur content: 500 ppm *The emission factors were :* -NOx 19,4 g/kWh -HC 0,77 g/kWh -CO 1,27 g/kWh -Particles 0,51 g/kWh The data is found in ''Exhaust emission from a two stroke lokomotive engine''. The ECE R49 is a steady state cycle for heavy duty truck engines. Consists of a sequence of 13 constant engine speed and load modes. Emissions are analysed for each test mode. Then the overall emission result is calculated as a (weighted) average from all test modes. The cycle is characterised by high average engine load and high exhaust gas temperature.
Literature Reference	Exhaust emissions from a two stroke locomotive engine, MTC rapport 96:4, Motortestcenter, Svensk Bilprovning, 1996
Notes	The heat value for diesel is 42,7 MJ/kg

About Inventory

Publication	www.ntm.a.se Data Documented by Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value

	since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM .
Practitioner	Strömberg, Jonas - SJ Cargo Group, Stockholm .
Reviewer	
Applicability	The data should not be used for detailed studies of transportation activities. More detailed data is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to obtain information in these matters. Railway traffic generally handles transportation of large heavy goods over long distances. Both electrically driven and diesel driven trains may be used. Electrically driven trains transport 95 % of the goods handled by train. Each truck of the trains may be assumed to have a loading capacity with regard to weight of 55 tonnes and a maximum gross weight of 80 tonnes. The trains are normally marshalled. Electrically driven combi train consists of trucks loaded with load carriers that also may be loaded and transported by truck. The share of goods transported by combi trains are about 5 % of the total amount of goods transported by electrically driven trains. Electyrically driven system trains are not recoupled on the way and always take the same route between two adresses. No marshalling is done, but a diesel engine may be used at the end points. The trains are generally fully loaded one way, and empty on the return trip, i.e. the utilisation level is about 50 % or higher. System trains ordinarily runs special transportation assignments for different types of industry. Diesel driven engines (T44) are mainly used for shunting and for regular traffic in sections where there is no aerial line. There are still some sections of the swedish railway system that are not electrified. SJ also uses smaller diesel engines (V5) for shunting. The V5 engine has a capacity of 400-500 tonnes gross weight and is not used for regular traffic. -- Marshalling -- The major part of the goods is marshalled at 6 main junctions where the goods are gathered and new trains are put together for new destinations. Shunting is generally done by diesel driven engines and is performed in two ways: -Hump shunting (valväxling) -Fly shunting (planväxling) -- Distance-- The railway network and the fact that the goods generally are marshalled means that the goods not always travel the shortest route between two destinations. When using the data, the distance may thus be difficult to assess. The company carrying out the transport should be contacted to get an accurate estimate of the distance. SJ has developed an environmentl data software with a databas of distances between 70 different places, concidering the infrastructure. The database does however not give information on which lines that arenot electrified. -- Bulky goods-- The data can be used for bulcy goods with the recalculation of the volume of the goods to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.
About Data	Locomotive: T44 Fuel: MK-1 Estimated loading: 535 tonnes. Fuel consumption: 3,5l/km. Sulpher in fuel: 100 ppm weight. Used testcycle: ECE R49. The data is based on tests on one lokomotive engine performed in a laboratory. This means that several parameters that influence the energy use and emissions in regular traffic are not concidered, e.g., climate, topography, driving technique, maintenance etc. Since the emissions depend on the engine speed and local conditions the emissions in actual operation may vary substatually. The test cycle was developed to represent long-distance traffic. The data is based on an average utilisation level of 55 %, based on statistics from 1993 from the Swedish State Railways (SJ). Today the average utilisation level is higher according to SJ due to different actions to use the trains more effective, and it is not possible to discern a difference in utilisation between electrically driven and diesel driven freight trains.
Notes	The person stated as ''Practitioner'' is the contact person for the data for transportation by train in NTM. Data is collected from NTM homepage, latest updated 1999 - 11 - 11. The data is continously updated and the user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: www.ntm.a.se

	The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation.Updated data for diesel trains and road transport are expected to be published before summer 2000. The major Swedish actors in the transportation business, which are members of NTM (e.g., SJ, BTL, ASG, etc.), will use the data as a basis for environmental assessment of different transportation alternatives.

SPINE LCI dataset: Dioctyl phthalate (DOP) production. ESA-DBP

Administrative	
Finished	Y
Date Completed	1992
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public.

Technical System	
Name	Dioctyl phthalate (DOP) production. ESA-DBP
Functional Unit	1 kg of dioctyl phthalate (DOP)
Functional Unit Explanation	Not applicable.
Process Type	Gate to gate
Site	Neste Oxo ABStenungsund
Sector	Materials and components
Owner	Neste Oxo ABStenungsund
Technical system description	DOP is produced through a number of reactions, in which orthoxylene, fuel oil and propylene are the main raw materials. DOP is the dominant plasticizer used in PVC. This process is included in the system described in: Jönsson Å, 1995, Life cycle assessment of flooring materials - a case study and methodological considerations. Licentiate thesis. Technical Enviroinmental Planning report 1995:3, Technical Environmental Planning, Chalmers University of Technology, Göteborg, Sweden Other processes in the CPM Database connected to the above publication: Linoleum flooring. ESA-DBP Vinyl flooring. ESA-DBP Solid wood flooring. ESA-DBP

System Boundaries	
Nature Boundary	Emissions to air inlcludes emissions from fuels.
Time Boundary	Data from Environmental Report in 1992.
Geographical Boundary	Data from Environmental Report from Neste Oxo AB in Stenungsund, Sweden.
Other Boundaries	Excerpt from the report (see 'Publication'): ''The production of phthalic anhydride occurs elsewhere but is included in the data given below, including transportation between phthalic anhydride production and plasticiser production.''
Allocations	Not applicable.
Systems Expansions	Not applicable.

About Inventory

Publication	Jönsson Å, 1995, Life cycle assessment of flooring materials - a case study and methodological considerations. Licentiate thesis. Technical Enviroinmental Planning report 1995:3, Technical Environmental Planning, Chalmers University of Technology, Göteborg, Sweden
Intended User	LCA practitioners.
General Purpose	This data set is included in the system described in a Licentiate thesis.
Detailed Purpose	Excerpt from the Licentiate thesis (see 'Publication') where this data set i included: ''The objectives and scope of this thesis are to assess what methodological LCA (Life Cycle Assessment) questions are specific to buildings and building materials, to compare LCA with other environmental assessment methods that may be applied to building materials, and to describe what environmental problems are associated with buildings and building materials. A literature study categorises and describes what information exists in the fields of environmental assessment of buildings and building materials, and for what purpose it is utilised.''
Commissioner	Not applicable - .

Availability	Public

Technical System	
Name	Dioctyl phthalate (DOP) production. ESA-DBP
Functional Unit	1 kg of DOP
Functional Unit Explanation	DOP- Dioctyl phthalate
Process Type	Gate to gate
Site	Neste Oxo AB, Stenungsund, Sweden
Sector	Chemicals and chemical products
Owner	Neste Oxo AB, Stenungsund, Sweden
Technical system description	(NB: the flowchart can be found in the reference report) Excerpt from the report, see 'Publication': ''DOP is a standard chemical product used KWH to adjust the softness of their products. (...) Refinery products are products such as naphtha and propane from the cracking process. The refinery have a multiple output of several products of which three are used is the production of DOP. (...) DOP is produced through a number of reactions in which propylene, fuel oil and orthoxylene are the main raw materials.'' This process is included in the system described in: Beckman T. (1997). Gutenberg versus IT. A Life Cycle Assessment of printed and CD-stored information. Technical Environmental Planning, Report 1997:3, Chalmers University of Technology. Gothenburg, Sweden. Other processes in the CPM Database also included in the above publication: - Manufacturing of CD-R (Compact Disc-Recordable). ESA-DBP - Manufacturing of CD-ROM (Compact Disc - Read Only Memory). ESA-DBP - Cultivation and felling of trees for papermaking. ESA-DBP - Cardboard production (MDF based). ESA-DBP - Production of copypaper. ESA-DBP - Production of orthoxylene. ESA-DBP

SPINE LCI dataset: Diode wafer production and assembly

Administrative	
Finished	Y
Date Completed	2000-03-02
Copyright	Ericsson
Availability	Official

Technical System	
Name	Diode wafer production and assembly
Functional Unit	One gram of diode with capsule type DO-214AA
Functional Unit Explanation	The motivation for choosing this functional unit is: · suitable unit to work with in an LCA of a private branch exchange (a complicated telecom product) · important component of the MD110 product system and many other electronic products. DESIGN The answers from component manufacturer one (CM1), component manufacturer two (CM2) and component manufacturer three (CM3) are for three different components but they all have they same capsule type, the DO-214AA. These facts are based on Ericsson technical specification of the component. Product specifications: CM1: Ericsson product number: RKZ 323 313/7 Ericsson description: Bidirectional breakdown diode, General: Bidirectional transient voltage suppressor designed to protect sensitive components. The suppressor is a clamping type with zener voltage 6,8 V to 150V and peak pulse dissipation is 600W Design general: moulded plastic similar to JEDEC DO-214AA. Intended for surface mounting. Dimensions: Height: 2,0-2,6 mm, Length: 5,1-5,6 mm, Width: 3,3-3,95 mm, Terminal thickness: 0,1-0,3 mm Weight: 0,087 g CM2 Ericsson product number: RKZ 323 312/1 Ericsson description: Schottsky diode 90V 0,77A General: The schottsky rectifier diode is for applications requiring low forward drop and small footprints. Design general: The case is D-64, inteded for surface mounting. Dimensions: Height: 1,8-2,4 mm, Length: 4,7-5,5 mm, Width: 2,3-2,8 mm, Terminal thickness: 0,9-1,6 mm Weight: 0,064 g CM3 Ericsson product number: RKZ 323 316/1 Ericsson description: Thyristor diode, transient voltage suppressor, bidirectional General: Bidirectional thyristor diode designed for subscriber line-card and terminal protection. Design general: Plastic case with tinned terminals intended for surface mounting on printed circuit board. Case: SOD 6 similary to DO-214AA. Dimensions: Height: 2,0-2,6 mm, Length: 2,61 mm, Width: 3,93 mm, Terminal thickness: 0,2 mm Weight: 0,181 g
Process Type	Gate to gate

Site	Not relevant
Sector	Manufacturing
Owner	Not relevant
Technical system description	This activity includes the diode wafer production and the final assembly of diodes with capsule type DO-214AA. The activity is an average based on information acquired from three manufacturers. The description of the process is supplied by manufacturer two, but is assumed to be general for this type of manufacture. The following process steps are included; Wafer factory: 1. Wafer preclean and oxidation 2. Ring masking 3. Mask etching 4. Ring doping 5. Ring oxidising 6. Mask to open active area 7. Etch oxide in active area 8. Deposition of barrier metal 9. Deposition of contact metal 10. Mask & Etch of back side for contact metal 11. Back side metal deposition 12. Probing Shipping to assembly plant. Assembly factory: 1. Wafer sawing 2. Silicon die bonding & soldering 3. Moulding & de-flashing 4. Trimming and forming 5. Testing & marking 6. Packing No detailed description was given by any of manufacturers. Additional information: Below are some additional information supplied by each of the included component manufacturers. --Component manufacturer one -- CM1 constitute a wafer fabrication unit front-end with a backend assembly area for the manufacture of Diodes, Transient Voltage Suppressors and Bridge Rectifiers. Component manufacturer one (CM1) specifies that 650000 units are produced equaling 57000 grams. The silicon die for the diode is produced inside the factory. Resource raw material quantities used in the manufacturing of the silicon die are small or supplied locally. The plant has a capacity to manufacture over 100 million units per month. Approximately 60% of all solid waste is recycled including all cardboard packaging. All emission data is taken from measurements from site emission points. All wastewater is treated on site by either primary or tertiary treatment and then discharged to sewer for further secondary treatment. All acid and other aqueous wastes including metal contaminated wastewater are treated in two wastewater treatment plants on site. The wastewater treatment is included in the activity. Initiatives have been successfully completed in water conservation with a 15% reduction in 1998; future projects are at an advanced stage including membrane technology utilisation to reduce water consumption by the recovery of wastewater allowing a 30% reduction in wastewater generation. Approximately 60 % of all solid waste from the facility is recovered and recycled or reused. Wastewater treatment plant sludge Non Toxic, Non Hazardous (As per the European waste catalogue and analysis completed) at 55% solids is reused as a landfill capping agent. N-Butyl Acetate, Xylene and W.N.R.D solvent wastes are recovered and reused as paint thinners. All other Hazardous waste is incinerated at (CM1) audited and accepted facilities. The reuse of sludge in incineration is not included. -- Component manufacturer two -- For component manufacturer two (CM2), the wafer factory is located in Malaysia and the assembly factory is located in Italy. The transport between the two factories is included in the data supplied by the manufacturer. Component manufacturer two (CM2) specifies that their transport figures are referred to the Wafer plant. The assembly data are not available, and thus not included for this manufacturer. Transport by road has been estimated by

	looking at maps. CM2 describes their plants as Class 1000 Wafer Fab and Class 10000 assembly and final test Facility. CM2 describes furthermore that the studied product is a Surface Mounting Schottky diode encapsulated in SMA. The Schottky barrier is formed by the deposition of barrier metal on n-epi silicon. It is at this interface that the rectifying contact is created. This type of metal to semiconductor contact allows for a lower forward voltage drop as compared to a diffused pn junction diode. The Schottky diodes incorporate a guard ring structure that is located at the perimeter of the die surface. This structure consists of a diffused p-well in the n-epi layer located at the semiconductor-oxide metal interface region. The p-type guard ring reduces the electrical field strength by injecting minority carriers into the n-epi layer. This structure is effecting a reverse biased pn avalanche junction used to protect the Schottky barrier from excessive voltage stress. The anode metallization consists of Ti, Ni, and Ag for solder attachment. The cathode metallization also consists of Ti, Ni, and Ag to create an ohmic contact with the n++ silicon substrate. This process step is some of the steps 8-12 in the Wafer factory. The cathode and anode side of the silicon die is soldered respectively to the relevant lead frame using a reflow soldering technique. After die attach the lead frame is encapsulated with an Epoxy resin compound followed by a curing period. A trimming operation followed by a lead forming and a Plating process is performed before the electrical final test. Marking and packing are the last two operations. The energy-ware, emissions and waste data are referred to the Wafer plant. The assembly data are not available. --Component manufacturer three -- Component manufacturer three (CM3) specifies that their annual production is 3,600,000 pieces. The silicon is purchased as a wafer. The die is manufactured on site. Emissions to air are via ion exchange filters located within system. All emissions to water are processed via the effluent system, located on site. Very little is sent to effluent system, as a filter system is in place. CM3 found it not possible to calculate emissions and waste per functional unit.

System Boundaries

Nature Boundary	The emissions to air and water have nature as recipient. Each parameter mentioned by the component manufacturers has been studied. No arameter has deliberately been disregarded when environmental impact has been studied. Included component manufacturers have not specified the same parameters. In the cases where only one manufacturer has stated a parameter this has been used.
Time Boundary	1998 The answer from the manufacturer arrived in 1998 and they measured in 1998. The process technology used is most certainly the best available as the factories are located in Ireland, Italy, Malaysia and England and the companies are well established.
Geographical Boundary	The technical system for this model is limited to the factory where the production takes place. The model is made up of answers from three component manufacturers, one from Ireland, one from Italy/Malaysia and one from England.
Other Boundaries	Delimitations to the system is the wafer fabrication and the final assembly step in the making of the diode. The production of the subparts (e.g. Epoxy resin, Solder paste, Copper lead wire and leadframe) of the diode is not included in this model The transportation of them to the factory is not included. For interested parties who wish to include the transport figures given from the manufacturers, can find the figures in the section Applicability.
Allocations	The manufacturers have not described how the allocation has been made. We did not decide or have any suggestions on how the manufacturer should allocate in their factory.
Systems Expansions	None.

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, unspecified
Represents	See 'Function'

Method	The data that are presented are calculated as a average based on information from three component manufacturers. The information from the manufacturers was acquired using a LCI data questionnaire. The average for each presented flow is calculated as follows: - First the amount of each flow per functional unit is calculated for each component manufacturer - Then the calculated amount for each component manufacturer is summed for each unique flow and divided by the number of included component manufacturers In the information supplied by the manufacturer, they had indicated whether the data for each flow were measured, estimated or calculated. Below is a detailed account of the calculation procedure. Definition of variables: CMn: Component manufacturer number n. Myn: Materials, emission, waste, energy (y) given in component answer n. ACyn: Amount of material y in component, expressed in mg (or similar) by component manufacturer n Wn: Weight of one piece of component, expressed in mg (or similar) by component manufacturer n. Nyn: The flow y expressed per functional unit from manufacturer n. Step 1. For CM1 sum AC1+..+.ACn Step 2: The sum AC11+..+.ACyn = W1 Step 3: Divide all flows between M11...M1n by W1 --> N11...N1n Step 4: Repeat Step 1 to 3 for all component manufacturers and for each flow. Step 5: Sum N1n+..Nyn and divide by the number of terms for each unique flow.(material input, emission etc.) An average calculation like above of up to three answers was made.

Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 3 states they use 6 mg for a diode which weighs 0,181 g. Hence, 0,006 / 0,181 = 0,033 g This is not an average value and the figure is based only on one answer. Notes: 64-19-7 is the CAS-number for acetic acid	Input	Refined resource	Acetic Acid	0.03			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM2: 0.006 mg/64 mg = 9.375e-5 g/g This is not an average value and the figure is based only on one answer.	Input	Refined resource	Ag	9.375E-05			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM3: 10 mg /181 mg = 0,055 g/g This is not an average value and the figure is based only on one answer.	Input	Refined resource	Au	0.055			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 0,087 dm3 for 1000 diodes. One diode weighs 0,0877 grams. According to http://www.chemfinder.com /cgi-win/cfserver.exe/ Butyl	Input	Refined resource	Butyl acetate	0.06			g	Technosphere	

Acetate has a specific gravity of 0,882 kg/dm3. Hence, 0,882 * 0,087 / 0,0877 = 0,0875 g Butyl Acetate The answer from component manufacturer 3 states they use 6 mg for a diode which weighs 0,181 g. Hence, 0,006 / 0,181 = 0,033 g Butyl Acetate Average value (0,0875 + 0,033)/2 = 0,06025 g Butyl Acetate This is an average value based on two answers. Notes: Butyl acetate has CAS number 123-86-4.									
Date concieved: 1998 Data type: Derived, unspecified Method: CM1: 166mg / 87,69 mg = 1,893 g/g CM2: 70 mg/64 mg = 1,093 g/g CM3: 170mg /181 mg = 0,939 g/g (CM1+CM2+CM3)/3 = 1,308 g Cu/g This is an average value based on three answers.	Input	Refined resource	Copper	1.308			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 1 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 1e-3/1000/0,0877 = 1,14e-5 g This is not an average value and the figure is based only on one answer. Notes: dichlorosilane has CAS-number 4109-96-0	Input	Refined resource	dichlorosilane	0.00001			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1: 57 000 g / 650 000 pieces --> 0,08777 g / diode 32kWh is consumed for 1000 diodes ---> 32/ 0,0877 Wh / g = 364,88 Wh /g diode Component manufacturer 2: Each diode weighs 64 mg. We had to adjust the materials really used in the product. 7,5 Wh / 0,064 g = 117,16 Wh / g diode (364,88 + 117,16)/2 = 241,022 Wh/g diode This is an average value based on two answers.	Input	Refined resource	Electricity	241.022			Wh	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM1: 278 mg / 87,69 mg = 3.17 g/g (Mold compound assumed by Ericsson to be Epoxy plastic) CM2: 32 mg/64 mg = 0.5 g/g CM3: 60 mg /181 mg = 0,33 g/g (CM1+CM2+CM3)/3 = 1.33 g EP/g This is an average value based on three answers.	Input	Refined resource	Epoxy	1.33			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 3 states they use 6 mg for a diode which weighs 0,181 g. Hence, 0,006 / 0,181 = 0,033 g This is not an average value and the figure is based only on one answer. Notes: Ethyl Alcohol has CAS-number 64-17-5	Input	Refined resource	Ethyl Alcohol	0.01657			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 0,039 dm3 for 1000 diodes. One diode weighs 0,0877 grams. According to	Input	Refined resource	H2O2	0.22			g	Technosphere	

	http://www.chemfinder.com /cgi-win/cfserver.exe/ H2O2 has a specific gravity of 1,4067 kg/dm3. Hence, 1,4067 * 0,039 / 0,0877 = 0,625 g H2O2 The answer from component manufacturer 2 states they use 1 mg for a diode which weighs 0,064 g. Hence, 0,001 / 0,064 = 0,0156 g H2O2 The answer from component manufacturer 3 states they use 5 mg for a diode which weighs 0,181 g. Hence, 0,005 / 0,181 = 0,0276 g H2O2 Average value (0,625 + 0,0156 + 0,0276)/3 = 0,222 g H2O2 This is an average value based on three answers.									
	Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 0,082 dm3 for 1000 diodes. One diode weighs 0,0877 grams. According to http://www.chemfinder.com /cgi-win/cfserver.exe/ H2SO4 has a specific gravity of 1,85 kg/dm3. Hence, 1,85 * 0,082 / 0,0877 = 1,729 g H2SO4 The answer from component manufacturer 2 states they use 1 mg for a diode which weighs 0,064 g. Hence, 0,001 / 0,064 = 0,0156 g H2SO4 The answer from component manufacturer 3 states they use 15 mg for a diode which weighs 0,181 g. Hence, 0,015 / 0,181 = 0,0828 g H2SO4 Average value (1,729 + 0,0156 + 0,0828)/3 = 0,609 g H2SO4 This is an average value based on three answers.	Input	Refined resource	H2SO4	0.6			g	Technosphere	
	Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 0,055 dm3 for 1000 diodes. One diode weighs 0,0877 grams. According to http://www.chemfinder.com /cgi-win/cfserver.exe/ HF (aq) has a specific gravity of 0,993 kg/dm3. Hence, 0,993 * 0,055 / 0,0877 = 0,6227 g HF (aq) This is not an average value and the figure is based only on one answer.	Input	Refined resource	HF	0.62			g	Technosphere	
	Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 0,018 dm3 for 1000 diodes. One diode weighs 0,0877 grams. According to http://www.chemfinder.com /cgi-win/cfserver.exe/ HNO3 (aq) has a specific gravity of 1,383 kg/dm3. Hence, 1,383 * 0,018 / 0,0877 = 0,284 g HNO3 (aq) This value is based on one answer.	Input	Refined resource	HNO3	0.28			g	Technosphere	
	Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 0,027 dm3 for 1000 diodes. One diode weighs 0,0877 grams. According to http://www.chemfinder.com /cgi-win/cfserver.exe/ HCl (aq) has a specific gravity of 0,909 kg/dm3. Hence, 0,909 * 0,027	Input	Refined resource	Hydrochloric acid	0.099			g	Technosphere	

/ 0,0877 = 0,279 g HCl (aq) The answer from component manufacturer 2 states they use 0,4 mg for a diode which weighs 0,064 g. Hence, 0,0004 / 0,064 = 6,25e-3 g HCl (aq) The answer from component manufacturer 3 states they use 2 mg for a diode which weighs 0,181 g. Hence, 0,002 / 0,181 = 0,011 g HCl (aq) Average value (0,279 + 6,25e-3 + 0,011)/3 = 0,09875 g HCl (aq) This is an average value based on three answers.									
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 0,09 m3 for 1000 diodes. One diode weighs 0,0877 grams. According to ISBN 91-27-72174-4, page 71 Hydrogen (g) has a specific gravity of 0,090 kg/m3. Hence, 0,09 *0,09 * 1e-3 / 0,0877 = 0,092 g Hydrogen This is not an average value and the figure is based only on one answer.	Input	Refined resource	Hydrogen	0.09			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 3 states they use 10 mg for a diode which weighs 0,181 g. Hence, 0,010 / 0,181 = 0,55 g This is not an average value and the figure is based only on one answer.	Input	Refined resource	Isopropanol	0.55			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM2: 250 mg/64 mg = 3.9 g/g This is not an average value and the figure is based only on one answer.	Input	Refined resource	Kraftliner	3.9			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 12000 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 12 * 0,001 / 0,0877 = 0,136 g Methanesulfonic Acid (75-75-2) /g diode This is not an average value and the figure is based only on one answer. Notes: Methanesulfonic Acid has CAS-number 75-75-2	Input	Refined resource	Methanesulfonic Acid	0.14			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 3 states they use 10 mg for a diode which weighs 0,181 g. Hence, 0,010 / 0,181 = 0,55 g This is not an average value and the figure is based only on one answer.	Input	Refined resource	Methanol	0.55			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 states they use 0,0035 mg for a diode which weighs 0,064 g. Hence, 0,0035e-3 / 0,064 = 5,47e-5 g This is not an average value and the figure is based only on one answer.	Input	Refined resource	Mo	0.000055			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 6,5 m3 for 1000 diodes. One	Input	Refined resource	N2	92.6			g	Technosphere	

diode weighs 0,0877 grams. According to ISBN 91-27-72174-4, page 71 N2 has a specific gravity of 1,25 kg/m3. Hence, 6,5 *1,25 / 0,0877 = 92,64 g N2 This is not an average value and the figure is based only on one answer.									
Date concieved: 1998 Data type: Derived, unspecified Method: CM2: 0,45 dm3 natural gas is used 0,45 dm3 /0,064 g diode (manufacturer 2) = 7,03125 dm3/g diode HHV is 39,89 MJ/m3 (ISBN 91-7548-544-3, page 116) ---> 7,03125e-3 * 39,89 = 0,28 MJ This is not an average value and the figure is based only on one answer. Literature: Brohammer, Produkekologi answer from one manufacturer	Input	Refined resource	Natural gas	0.28			MJ	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 40 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 40e-3/1000 / 0,0877 = 4,56e-4 g NH3 The answer from component manufacturer 3 states they use 8 mg for a diode which weighs 0,181 g. Hence, 0,008 / 0,181 = 0,0442 g NH3 Average value (4,56e-4 + 0,0442)/2 = 0,0223 g NH3 This is an average value based on two answers.	Input	Refined resource	NH3	0.0223			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 1000 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 1000e-3/1000 / 0,0877 = 0,00114 g NH4Cl This is not an average value and the figure is based only on one answer.	Input	Refined resource	NH4Cl	0.00552			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM2: 0,004 mg/64 mg = 0,0000625 g/g CM3: 10 mg /181 mg = 0,055 g/g (CM2+CM3)/2 = 0,0276 g/g This is an average value based on two answers.	Input	Refined resource	Ni	0.0276			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 700 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 700e-3/1000 / 0,0877 =7,98e-3 g Nickel chloride /g diode This is not an average value and the figure is based only on one answer. Notes: Nickel chloride has CAS-number 13931-83-4	Input	Refined resource	Nickel chloride	0.00387			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: The data was given by CM1 in dm3. This figure has been transformed to MJ using Energifakta, 1994 figures for Eo1 furnace oil as follows: 1m3=9960kWh. 1kWh=3.6MJ reference :. 1m3=9960*3.6MJ=35856MJ Given data: 0.0068 dm3 Calculations: 0.0068*1e-	Input	Refined resource	Oil	0.244			MJ	Technosphere	

3*35856=0.244 MJ This is not an average value and the figure is based only on one answer.									
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 0,046 m3 for 1000 diodes. One diode weighs 0,0877 grams. According to ISBN 91-27-72174-4, page 71 O2 has a specific gravity of 1,43 kg/m3. Hence, 0,046 *1,43 / 0,0877 = 0,75 g O2 This is not an average value and the figure is based only on one answer.	Input	Refined resource	Oxygen	0.75			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM1: 0,05 mg / 87,69 mg = 0,00057 g/g This is not an average value and the figure is based only on one answer.	Input	Refined resource	Pb	0.00057			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 0,002 dm3 SC resist for 1000 diodes. One diode weighs 0,0877 grams. I assume SC resist has a specific gravity of 1,0 kg/dm3. Hence, 1,0 * 0,002 / 0,0877 = 0,0228 g SC resist The answer from component manufacturer 2 states they use 4 mg for a diode which weighs 0,064 g. Hence, 0,004 / 0,064 = 0,0276 g Etch resist Average value (0,0228 + 0,0276)/2 = 0,0252 g Photoresist This is an average value based on two answers.	Input	Refined resource	Photoresist	0.0252			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 states they use 0,025 mg for a diode which weighs 0,064 g. Hence, 0,025e-3 / 0,064 = 3,9e-4 g PVC This is not an average value and the figure is based only on one answer.	Input	Refined resource	Polyvinyl Chloride	0.00039			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 6 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 6e-3/1000 / 0,0877 = 6,84e-5 g silane Accroding to http://www.chemfinder.com /cgi-win/cfserver.exe/ Silane is another name for Silicon Tetrahydride CAS no. 7803-62-5 This is not an average value and the figure is based only on one answer. Notes: Silicon Tetrahydride has CAS-number 7803-62-5	Input	Refined resource	Silicon Tetrahydride	0.0000684			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM1: 5,004mg / 87,69 mg = 0,057 g/g (Tin concentrate plus tin additive) CM3: 10 mg /181 mg = 0,055 g/g (tin plate solution) (CM1+CM3)/2 = 0,056 g/g This is an average value based on two answers.	Input	Refined resource	Sn	0.056			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: CM2: 2.5 mg/64 mg = 0,039 g/g This is not an average value and the figure is	Input	Refined resource	Solder	0.039			g	Technosphere	

based only on one answer.									
Date concieved: 1998 Data type: Derived, unspecified Method: CM1: 6mg / 87,69 mg = 0,068 g/g CM3: 1,5 mg /181 mg = 0,0083 g/g (CM1+CM3)/2 = 0,038 g/g This is an average value based on two answers.	Input	Refined resource	Solder cream	0.038			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 states they use 0,002 mg for a diode which weighs 0,064 g. Hence, 0,002e-3 / 0,064 = 3,13e-5 g This is not an average value and the figure is based only on one answer.	Input	Refined resource	Ti	1.449E-05			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 1000 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 1000e-3/1000 / 0,0877 = 0,011 g trisodium citrate This is not an average value and the figure is based only on one answer. Notes: Trisodium Citrate has CAS-number 68-04-2.	Input	Refined resource	Trisodium Citrate	0.011			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a use of 26000 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 26000e-3/1000 / 0,0877 = 0,296 Xylene /g diode This is not an average value and the figure is based only on one answer.	Input	Refined resource	Xylene	0.296			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states an emission of 94 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 94e-3/1000/ 0,0877 = 0,00107 g acetic acid This is not an average value and the figure is based only on one answer.	Output	Emission	Acetic Acid	0.00107			g	Air	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 states they emit 4,7 mg acetone for a diode which weighs 0,064 g. Hence, 0,0047 / 0,064 = 0,073 g This is not an average value and the figure is based only on one answer.	Output	Emission	Acetone	0.073			g	Air	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states an emission of 7000 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 7000e-3/1000 / 0,0877 = 0,0798 g BOD5 The answer from component manufacturer 2 states they emit 0,16 mg for a diode which weighs 0,064 g. Hence, 0,16e-3 / 0,064 = 0,0025 g BOD5 Average value (0,0798 + 0,0025)/2 = 0,04 g BOD5 This is an average value based on two answers.	Output	Emission	BOD	0.04			g	Water	

Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 states they emit 4,1 mg for a diode which weighs 0,064 g. Hence, 0,0041 / 0,064 = 0,064 g This is not an average value and the figure is based only on one answer.	Output	Emission	Butyl acetate	0.064			g	Air	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 states they emit 0,25 mg for a diode which weighs 0,064 g. Hence, 0,25e-3 / 0,064 = 3,9e-3 g This is not an average value and the figure is based only on one answer.	Output	Emission	Cl-	0.0039			g	Water	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states an emission of 3700 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 3700e-3/1000/ 0,0877 = 0,042 g CO This is not an average value and the figure is based only on one answer. Notes: CO = Carbon monoxide	Output	Emission	CO	0.042			g	Air	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states an emission of 30000 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 30000e-3/1000 / 0,0877 = 0,342 g COD5 The answer from component manufacturer 2 states they emit 0,25 mg for a diode which weighs 0,064 g. Hence, 0,25e-3 / 0,064 = 0,0039 g COD5 Average value (0,342 + 0,0039)/2 = 0,173 g COD5 This is an average value based on two answers.	Output	Emission	COD	0.00362			g	Water	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states an emission of 2000 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 2000e-3/1000 / 0,0877 = 0,023 g F- The answer from component manufacturer 2 states they emit 0,009 mg for a diode which weighs 0,064 g. Hence, 0,009e-3 / 0,064 = 1,4e-4 g F- Average value (0,023 g + 1,4e-4 g)/2 = 0,0116 g F- This is an average value based on two answers.	Output	Emission	F-	0.012			g	Water	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states an emission of 2000 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 2000e-3/1000/ 0,0877 = 0,022 g F- This is not an average value and the figure is based only on one answer.	Output	Emission	F-	0.022			g	Air	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 states they emit 4,9 mg for a diode which weighs 0,064 g.	Output	Emission	HC	0.076			g	Air	

Hence, 4,9e-3 / 0,064 = 0,076 g This is not an average value and the figure is based only on one answer.									
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 states they emit 0,95 mg for a diode which weighs 0,064 g. Hence, 0,95e-3 / 0,064 = 0,0148 g This is not an average value and the figure is based only on one answer.	Output	Emission	HF	0.0148			g	Air	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states an emission of 170 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 170e-3/1000 / 0,0877 = 1,938e-3 g HNO3 The answer from component manufacturer 2 states they use 0,95 mg for a diode which weighs 0,064 g. Hence, 0,95e-3 / 0,064 = 0,0148 g HNO3 Average value (1,938e-3 + 0,0148)/2 = 8,369e-3 g HNO3 This is an average value based on two answers.	Output	Emission	HNO3	0.00837			g	Air	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states an emission of 1000 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 1000e-3/1000/ 0,0877 = 0,011 g NH3 This is not an average value and the figure is based only on one answer.	Output	Emission	NH3	0.011			g	Air	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states an emission of 6400 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 6400e-3/1000/ 0,0877 = 0,073 g NO2 This is not an average value and the figure is based only on one answer.	Output	Emission	NO2	0.073			g	Air	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states an emission of 6000 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 6000e-3/1000 / 0,0877 = 0,064 g NO2- This is not an average value and the figure is based only on one answer.	Output	Emission	NO2-	0.064			g	Water	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states an emission of 280 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 280e-3/1000 / 0,0877 = 0,00319 g PO43- This is not an average value and the figure is based only on one answer.	Output	Emission	PO43-	0.003			g	Water	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 states they emit 0,0032 mg for a diode which weighs 0,064 g. Hence, 0,0032e-3 / 0,064 =	Output	Emission	Sn	0.00005			g	Water	

5e-5 g tin This is not an average value and the figure is based only on one answer.								
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states an emission of 2200 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 2200e-3/1000/ 0,0877 = 0,025 g SO2 This is not an average value and the figure is based only on one answer.	Output	Emission	SO2	0.025			g	Air	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 states they emit 0,8 mg for a diode which weighs 0,064 g. Hence, 0,8e-3 / 0,064 = 0,0125 g SO42- This is not an average value and the figure is based only on one answer.	Output	Emission	SO42-	0.0125			g	Water	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states an emission of 10000 mg for 1000 diodes. One diode weighs 0,0877 grams. Hence, 10000e-3/1000 / 0,0877 = 0,114 g suspended solids	Output	Emission	Suspended solids	0.11			g	Water	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 states they emit 0,13 mg for a diode which weighs 0,064 g. Hence, 0,13e-3 / 0,064 = 0,002 g Trichloroethylene This is not an average value and the figure is based only on one answer.	Output	Emission	Trichloroethylene	0.002			g	Air	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 states they emit 1,8 mg for a diode which weighs 0,064 g. Hence, 1,8e-3 / 0,064 = 0,028 g trimethyl benzene This is not an average value and the figure is based only on one answer. Notes: Trimethyl Benzene has CAS-number 25551-13-7	Output	Emission	Trimethyl Benzene	0.028			g	Air	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 states they use 6,5 mg for a diode which weighs 0,064 g. Hence, 6,5e-3 / 0,064 = 0,101 g Xylene This is not an average value and the figure is based only on one answer.	Output	Emission	Xylene	0.101			g	Air	
Date concieved: 1999 Data type: Derived, unspecified Method: 1 gram diode output is the base for all figures in this model.	Output	Product	Diodes	1			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: I assume all butyl acetate used in the process is wasted but recycled according to manufacturer 1. This is not an average value and the figure is based only on one answer.	Output	Residue	Butyl acetate	0.06			g	Technosphere	

Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 state 1,14 mg waste of mud is generated for a diode which weighs 0,064 g. Hence, 1,14e-3 / 0,064 = 0,0178 g mud This is not an average value and the figure is based only on one answer.	Output	Residue	Mud	0.018			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: I assume all photo resist used in the process is wasted but recycled according to manufacturer 1. This is not an average value and the figure is based only on one answer.	Output	Residue	Photoresist	0.0252			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 state 0,6 mg waste of solvents is generated for a diode which weighs 0,064 g. Hence, 0,6e-3 / 0,064 = 9,375e-3 g solvents This is not an average value and the figure is based only on one answer.	Output	Residue	Solvent	0.009375			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: The answer from component manufacturer 2 state 0,05 mg waste of chlorinated solvents is generated for a diode which weighs 0,064 g. Hence, 0,05e-3 / 0,064 = 7,81e-4 g solvents This is not an average value and the figure is based only on one answer.	Output	Residue	Solvents, chlorinated	0.000781			g	Technosphere	
Date concieved: 1998 Data type: Derived, unspecified Method: Component manufacturer 1 states a waste amount of 0,026 dm3 for 1000 diodes. One diode weighs 0,0877 grams. According to http://www.chemfinder.com /cgi-win/cfserver.exe/ the specific gravityof xylene is 0,862 kg/dm3. Hence, 0,026 * 0,867 / 0,0877 = 0,257 g xylene /g diode This is not an average value and the figure is based only on one answer.	Output	Residue	Xylene	0.257			g	Technosphere	

About Inventory	
Publication	Not available -- Data documented by: Anders Andrae, Ericsson Business Networks AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The intended use for this LCI
General Purpose	The general purpose with this LCI model was for application in a LCA project at Ericsson Business Networks. The main goal of the study is; to compare the potential environmental impacts associated with an old (BC 8) and a new model (BC 10) of a private branch exchange (PBX) system, namely the MD110 system, and an additional objective is to include comparisons between different stages of the life cycle (e.g. manufacturing, use and end of life) of the system. The system, PBX MD110, is designed, developed and delivered by Ericsson Enterprise Systems AB.

	Life-Cycle Assessment methodology (following the ISO14040 standards for LCAs) will be used to determine the environmental impacts. The main purpose of the study for Ericsson is; - to learn, test and evaluate the LCA-methodology as a tool for assessing environmental improvement options in the product design process, and to make up concrete product guidelines regarding design for environment (DfE) and - to evaluate environmental aspects in new design. The relative importance for different life cycle stages may also be an important input in the internal work with an Environmental Management System for Ericsson Enterprise Systems. Another purpose of the study is; to collect and qualify data from suppliers and literature in order to build up a database for this and future LCA activities and within the project, it is also intended to analyse the possibilities to use the study as a base for future work regarding a type III ecolabeling project within Ericsson. The intended audience of the report from the project is; Ericsson's personnel: project management, system management, design, marketing and sales organisation, and thus also (in an extracted version) the Ericsson customers.
Detailed Purpose	Map a diode manufacturing/assembly process from an environmental standpoint in a structured procedure. The purpose of the project was to collect resource consumption data and emission data connected with the silicon wafer production and final assembly of diodes and resembling components in our telecom products. The usage for this set of data are life cycle assessments where diodes are part of the studied system. Note: This model is one of in total eighteen models compiled at Ericsson, describing 16 component groups in the PBX. The division into component groups is based on structural resemblance, electrical function and material contents of the different components. -- Below is a list of the component groups and corresponding models that have been compiled: 1. Cables - Model: Cable assembly 2. Capacitors and filters; hole mounted devices - Model: Capacitor for hole mounting assembly 3. Capacitors; surface mounted devices - Model: Capacitor for surface mounting assembly 4. Connectors and holders - Model: Connector assembly 5. Diodes - Model: Diode wafer production and assembly 6. Display units and indicators - Model: Liquid crystal display assembly 7. Microcircuits, oscillators, quartz crystal units and delay lines (2 models) - Models: 1. Integrated circuit capsule assembly and 2. Si wafer production and Si wafer processing for integrated circuits (these models are interlinked) 8. Other - Model: ''Other'' electronic component assembly 9. Potentiometers - Model: Potentiometer assembly 10. Printed boards - Model: Printed board assembly 11. Relays - Model: Relay assembly 12. Resistor networks - Model: Resistor network assembly 13. Resistors, varistors and thermistors; hole mounted devices - Model: Resistor for hole mounting assembly 14. Resistors; surface mounted devices - Model: Resistor for surface mounting assembly 15. Transformers and inductors - Model: Inductor assembly 16. Transistors and opto couplers (2 models) - Models: 1. Transistor assembly and 2. Si wafer production and Si wafer processing for transistors (these models are interlinked)

Applicability	This set of data can be applied to diodes in electronic equipment if you know how much the diode weight. Here follows a more detailed description of transports of materials and components to the

respective manufacturer factories. These transports are not included in the model.

CM1 = Component manufacturer one

The calculation for all modes of transport is done like this: First the total transportation work per functional unit is calculated for each included component manufacturer. Then the total transportation is summed and divided by the number of included component manufacturers. This gives the average value for transportation by each mode of transport.

-- Truck transportation: --

Component manufacturer one (CM1):

Weight of component: 0.08777 g

Leadframe with weight 0.166 g is transported 400 km by road i.e. 0.166 g*400 km, Mold compound 0.278 g*200 km and Solder paste 0.0056 g*200.

The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives:

123.12 gkm/0.08777 = 1402.75 gkm/g diode

Component manufacturer two (CM2):

Weight of component: 0.064 g

Silicon with weight 0.0025 g is transported 900 km by road i.e. 0.0025 g*900 km,

This gives:

2.25 gkm/0.064 = 35.16 gkm/g diode

Component manufacturer three (CM3):

Weight of component: 0.181g

Copper leadframe with weight 0.06 g is transported 120 km by road i.e. 0.06 g*120 km, Epoxy resin 0.06 g*120 km, Copper jumper 0.03 g * 2000 km, Silicon die 0.03 g ' 120 km and Solder paste 0.0015 g*2000 km.

The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives:

81 gkm/0.181 g = 447.51 gkm/g diode

This gives the average total transportation work by truck for CM1 and CM2:
(CM1+CM2+CM3)/3 = 628.47 gkm/g

-- Airplane transportation: --

The answer from component manufacturer 3 states they transport 30 mg of Silicon die 2000 km by air for a diode which weighs 0,181 g.

Hence,
30e-3 / 0,181 * 2000 = 331,41 gkm/g diode

-- Boat transportation: --

Component manufacturer one (CM1):

Weight of component: 0.08777 g

Leadframe with weight 0.166 g is transported 100 km by boat i.e. 0.166 g*100 km, Mold compound 0.278 g*12000 km and Solder paste 0.056 g*700.

The total transportation work is calculated as follows: the weight of the materials and components multiplied by distance divided by the weight of the component. This gives:

3356.52 gkm/ 0.08777 g = 38242.22 gkm/g

Component manufacturer one (CM3):

Weight of component: 0.181 g

Epoxy resin with weight 0.06 g is transported 2000 km by boat i.e. 0.06 g*2000 km,

120 gkm/ 0.181 g = 662.98 gkm/g

Average:

	(CM1+CM3)/2 = 19452,6 gkm/g diode
About Data	The data is based on information from one Irish, one Italian and one British manufacturer. The information was gathered using a life cycle inventory questionnaire. All flows are not average values and where there were only one manufacturer stating a certain flow, this one was chosen in the model. Of the flows about little more than 76 % are not average values.The flows for Raw material input of Butyl acetate, Copper, Epoxy resin, H2O2, H2SO4, HCl, NH3, Ni, Photoresist, Sn, Solder cream, emission to Air of HNO3, emission to water of BOD, COD, F- and Energy ware input of Electricity are average values. In specific QMetaData for each flow, we have indicated specifically for each flow how many manufacturers have been included. The figures in the original answer from the manufacturers should all have a special tag telling if the value has been calculated, measured or estimated or a combination of two or three of them. Ericsson specifically told the manufacturers to do so. The result is that approximately 12 % of the flows used in all manufacturers answers were only calculated, 45 % were only estimated, 41 % were only measured and 2 % were first estimated and then calculated. The outline of the LCI data questionnaire that were used in the inventory follows below. No limitations or specifications were set for which substances they had to account -- LCI data questionnaire -- Transport description: Material type, Used weight of Material (g)/functional unit, Transport by road of Material (km), Transport by boat of Material (km), Transport by rail of Material (km). We here only asked for flows exceeded 2% by weight of the material declaration of the component. Additional information was also asked for and here some manufacturers mentioned they had aeroplane transport instead of some of the other transport modes.´ Process description. Description of the entire production at the plant/site and a technical description of the plant production. Description of the production line of the studied product. Flow chart of process steps for production of the studied product. Technical description of the production line. A very short description of each unit operation. Data quality. For every figure you give, give an account on how you gatherd it. C = calculated, E = estimated, M = measured. General LCA-related information on the production system (Allocation procedures, system boundaries, etc.). Additional information. (e.g. planned changes in production rate) Material, components and natural resource input, etc. We told them to express data in amount per functional unit. Name of material, component or resource. Used amount(mg). Amount In Product(mg). Additional information Energy-ware input Energy -ware source. Quantity/functional unit. Unit. Energy-ware supplier, production site (address). Suppliers of transport (address). Additional information. Emissions. Emissions to air. Indicate whether emissions from energy use are included in the data. Name of emission to air. Emission to air/functional unit (mg). Additional information. Emissions to water. Indicate if data describes emissions going to external purification plant or directly to recipient. Name of emission to water. Emission to water/functional unit (mg). Additional information. Emissions to soil. Name of emission to soil. Emission to soil/functional unit (mg). Additional information. Waste. Name of waste. Waste/functional unit (mg). Recycled/functional unit (mg). Additional information.

SPINE LCI dataset: Dismounting of bearing

Administrative	
Finished	Y
Date Completed	2002-12-18
Copyright	
Availability	Public

Technical System	
Name	Dismounting of bearing
Functional Unit	1.2 ton bearing
Functional Unit Explanation	One SKF spherical roller bearing 232/530 weighs 1.2 ton.
Process Type	Unit operation
Site	Stora Enso Hylte ABHylte Mill S- 314 81 HYLTEBRUK Sweden
Sector	Construction
Owner	Stora Enso Hylte ABHylte Mill S- 314 81 HYLTEBRUK Sweden
Technical system description	This activity describes the dismounting of bearing. The roller bearing is dismounted from the soft calender roll of a paper machine at Storaenso AB in Hyltebruk using a manual hydraulic pump and a small amount of lubricant.

System Boundaries	
Nature Boundary	Nor the bearings or the lubricant enters from or leaves to the nature.
Time Boundary	Data is collected autumn 2002. No changes are planned for the nearest future.
Geographical Boundary	This dismounting procedure is performed at Storaenso, Hyltebruk, Sweden.
Other Boundaries	
Allocations	Because of that the dismounting takes place two times during the bearings lifetime, the double amount of mounting fluid each time is used. The density of the mounting fluid is 0.894 kg/l.
Systems Expansions	Not applicable

Flow Data	
General Activity QMetaData	
Date Conceived	2002-09-01- 2002-12-31

About Inventory	
Publication	Master thesis: LCA based solution selection. Helene Berg and Sandra Häggström, Chalmers University of Thechnology, December 2002. -------------- Data documented by sandra Häggström, M Sc. student at Chalmers University of Technology and SKF. Documentation reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-03-21.
Intended User	Product developer at SKF.
General Purpose	The data documentation is accomplished as a part of the thesis work ''LCA-based solution selection'', performed at Chalmers University of Technology by Helene Berg and Sandra Häggström.
Detailed Purpose	The purpose for our study is to compare a coated roller bearing to a non-coated, from cradle to grave. We have chosen paper machines as user phase. The bearing is mounted on a soft calender roll in both cases, and lubricated with circulating oil.
Commissioner	Victoria Wikström - SKF Sverige AB D1S3 415 50 Göteborg .
Practitioner	Sandra Häggström - .
Reviewer	Olle Ramnäs -
Applicability	Presumably on all bearings being dismounted from a soft calender in a paper machine.
About Data	Data is collected by inteviewing Dan Hedin and Bernt Petersson at Storaenso, Hyltebruk.

SPINE LCI dataset: Disposal of polyethylene to landfill.

Administrative	
Finished	Y
Date Completed	2003-01-10
Copyright	
Availability	Public

Technical System	
Name	Disposal of polyethylene to landfill.
Functional Unit	1000 kg of polyethylene
Functional Unit Explanation	Disposal of a tonne of polyethylene waste in accordance with the legal requirements was used as a functional unit.
Process Type	Gate to grave
Site	Europe
Sector	Waste management
Owner	Europe
Technical system description	The present analysis of waste treatment is based on the study ''Life cycle inventories of disposal processes - Basics for integration of the disposal in life cycle assessments'' (ESU-ETHZ 1996). This activity describes the disposal of 100% polyethylene wastes to the landfill. Polyethylene(PE) wastes are collected, transported and deposited directly to the reactor

	landfill. These data represent the situation in Switzerland in year 1995. The results are shown as an overall reactor landfill process including landfill gas recovery, waste water treatment of the leaching water and sewage treatment. Waste collection and transportation are also included into the study. The material content of the Polyethylene(PE) results from the chemical structural formula and the literature, and as follows: C (fossil)=841 kg/t PE H = 141 kg/t PE N = 0,7 kg/t PE Cl = 1,7 kg/t PE S = 0,5 kg/t PE Ash = 12 kg/t PE Density = 0,92-0,95 t/m3 Water content = 3,6 kg/t PE Upper heating value = 45,8 GJ/t Lower heating value = 39 GJ/t (PE should be regarded as PE/PP (Polypropylene) with a low water content) Waste collection and transportation An average distance of 10 km/t waste was assumed. The diesel consumption is 4 l/t waste. The transportation is carried out by truck. Reactor landfill The monitored phase lasts 150 years (processes included: chemical processes, leaching water formation, leaching water treatment, gas use). The degradability of the plastic in the monitored phase was estimated to be 5%. Before deposition, the amount of waste is weighed and recorded. The wastes are then distributed and compacted at the reactor landfill using compactors. Both leaching water and landfill gas are collected by means of leaching water lines. Leaching water is fed to a processing installation for treatment. Treatment of sewage sludge is also taken into account. On completion of the methane phase, the landfill material is allowed to settle for a period of time. Then the landfill surface is sealed with clay and earth, and recultivated. In the study it is assumed that the landfill cover is permiable. The energy expenditure in the operation consists of waste addition and compaction using construction machinery, the construction of the drainage system, and the operation of the landfill gas pumps and buildings. (SAEFL) Literature reference: Life Cycle Inventories for Packagings. Swiss Agency for the Environment, Forests and Landscape (SAEFL). Environmental Series No. 250/I-II. Waste. 1998. For more literature references see: ''About data''.

System Boundaries

Nature Boundary	In the reactor landfill process, the landfill gas incineration is integrated in the system boundaries and considered as a disposal process to ensure legal requirements. The results are shown as an overall reactor landfill process including landfill gas recovery, waste water treatment of the leaching water and sewage treatment. Waste collection and transportation are also included into the study. All emissions (to air, water, ground) are included.
Time Boundary	Data represent situation in Switzerland in year 1995. The data were updated in 1998. The data were collected in the period from 1993 to 1995, except for energy and transport values; these apply to the situation of 1990.
Geographical Boundary	Primarily, areas relevant to the economic region of Switzerland were investigated. Where possible and meaningful, the economic region was expanded. In such cases, the process data are based on import statistics that involves production countries important to Switzerland.
Other Boundaries	Energy production is regarded as a by-product and is free from emissions. The energy produced in the reactor landfill is reconciled directly with the energy consumption of the reactor landfill. This procedure is based on the assumption that the energy produced is needed simultaneously in the same plant.
Allocations	Not applicable
Systems Expansions	Not applicable

About Inventory

Publication	Life Cycle Inventories for Packagings. Swiss Agency for the Environment, Forests and Landscape (SAEFL). Environmental Series No. 250/I-II. Waste. 1998. -- Data documnented by: Anastassia Manuilova. Chalmers University of Technology and Akzo Nobel Surface Chemistry AB. Data reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-05-28
Intended User	LCA practitioners in industry,
General Purpose	To analyse the treatment and disposal processes of used packaging
Detailed Purpose	To calculate the environmental loads from treatment and disposal of plastic packaging. The data were used in the Master of Science thesis work ''Life Cycle Assessment of Industrial Packaging for Chemicals''. Anastassia Manuilova. Chalmers University of Technology and Akzo Nobel Surface Chemistry AB. 2003. The overall aim of the study was to evaluate the potential environmental effect of steel and plastic packaging used at Akzo Nobel site Stenungsund over the entire life cycle with emphasis on reuse and recycling.

SPINE LCI dataset: Dry wood chips fired plant for heat and power production - Large plant

Administrative	
Finished	Y
Date Completed	1999-08-30
Copyright	
Availability	Public

Technical System	
Name	Dry wood chips fired plant for heat and power production - Large plant
Functional Unit	1 kWh produced and delivered heat.
Functional Unit Explanation	The emissions and use of resources and raw materials are associated with the net production of 1 kWh heat.
Process Type	Gate to gate
Site	Sweden
Sector	Grid electricity and district heat
Owner	Sweden
Technical system description	BRIEF DESCRIPTION: This technical system describes the incineration process in a wood chips fired plant for heat and power production. The plant is located in Sweden and is fired with dried wood chips and wood briquettes when the drier is shutdown. The heat is delivered to a district heating net. Production of materials, chemicals and electricity and transport, used in association with the fuel chain and the operation and maintenance of the plant are not included. TECHNICAL DATA FOR THE STUDIED PLANT: Average annual time of use (hours): 5251/4865 Total electric power output (MW): 30 Total thermal output (MW): 128 Annual total fuel use (MWh): 529 884

	Normal annual production of heat (MWh): 354 555 Normal annual production of electricity (MWh): 99 026 Degree of thermal efficiency (%): 85,6 PROCESS DESCRIPTION: The plant consists of two steam boiler units of about 80 MW thermal and electric power output each. The wood chips are dried in a steamdryer before combustion. When the dryer is shutdown, wood briquettes are used as fuel. The dust is removed from the flue gas in an electrostatic precipitator. INCLUDED OPERATIONS: The process of the study consists of the following operations: - The feeding of the dry wood chips wood into the combustion process. - The combustion process. - The removal of dust from the flue gas in the electrostatic precipitator. - The internal treatment of the residues from the combustion process. - The internal consumption of electricity. - The internal consumption of chemicals used in the flue gas system and in the feed water treatment. - The NOx control system. NOx CONTROL: Both boilers are equiped with SNCR systems with urea as the reduction agent and flue gas recirculation. - SNCR (Selective Noncatalytic Reduction) describes a method for reducing the NOx already formed during the combustion process. In the process, an aqueous reduction agent mixed in water or steam is injected into the furnace during the combustion process. The reduction agent reduces the NOx and forms nitrogen and water. - Flue gas recirculation describes a method for limiting the NOx-formation during the combustion process. The process involves temperature and air supply optimization during the combustion process. Combustion at low temperature and with a low air factor reduces the NOx level. OTHER FLUE GAS CLEANING SYSTEMS: - For the removal of dust from the flue gas an electrostatic precipitator is used. In an electrostatic precipitator the dust particles are electrified and then separated from the flue gas stream by passing through an electric field with largest possible intensity. - Due to the low sulphur content in wood fules, no reduction of the sulphur content in the flue gas is needed.

System Boundaries	
Nature Boundary	CRITERIAS USED FOR SELECTING FLOWS: Most data for reported in- and outflows are normally measured and reported once yearly in a public environmental report. The emission of HC is not measured.
Time Boundary	APPLICABLE TIME OF SYSTEM: This inventory was conducted using data mainly from 1996. The data consists of average data on a year basis. This data is assumed to be valid until new national or local regulations are enforced in Sweden.
Geographical Boundary	GEOGRAPHICAL EXTENSION This inventory has been conducted on a dry wood chips fired plant for heat and power production in Sweden, with swedish regulations, applicable during 1996. The collected data should only be used for swedish conditions.
Other Boundaries	NOTES OF EXCLUDED TECHNICAL SYSTEMS: The following operations have been excluded from the system: - The distribution of district heat from the plant to the consumers. - Building of the plant and the district heating net. - The cradle to gate of the internal electricity consumption. - The production of the dried wood chips fuel. - The transportation of the fuel to the plant. - The transportation of the residues from the combustion and cleaning processes to the landfill or back to the forest. - The processes at the landfill such as leaching, decomposition etc. - The spreading of the ashes in the forest. EXCLUDED FLOWS - The chemicals used for feed water treatment. - The water consumption in the process.
Allocations	PRINCIPLE APPLIED: In a combined power and heating plant two products of economic value are produced. For operation and maintenance of the plant the use of resources and the emissions are associated in relation to the net production of heat and power respectively. For the use of resources and the emissions that are specific for the electric power production are allocated to that production. Equivalent to this the use of resources and the emissions specific for the heat production are allocated to that production. Note: When both heat and power are produced the allocation between the products are the same. That is the environmental load for 1 kWh produced heat are the same as for 1 kWh produced electrical power.

	DESCRIPTION:
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1996
Data Type	
Represents	N/A
Method	All data reported are related to the functional unit 1 kWh heat produced and delivered. The data is originally given as the total yearly amount of an input (fuel, chemical, electricity etc.) to or an output (emission, product etc.) from the energy plant. The inputs and outputs are then related to the functional unit by dividing the total yearly amount with the yearly amount of produced heat and multiplying with the fraction of the total production that are associated with the heat production. For some flows specific information is given, see each flow.
Literature Reference	Data are in general recieved from ''Miljörapport 1996, Borås Energi AB''.
Notes	The parameters presented are chosen because they are available in the annual environmental report of the plant. Data can be missing if it is not reported in the report. The type of data reported is governed by the inspection authority. All values are reported with 3 figures. The data are however seldom that accurate.

About Inventory

Publication	LCA värme, Vattenfalls Livscykelanalyser, Produktion av värme; Maria Münter, Emanuel Nandorf, Pernilla Strömberg, Andrea Wallenius; SwedPower AB, Miljö & Kvalitet; 1999-07-01. -- Data documented by: Maria Münter, Emanuel Nandorf, Pernilla Strömberg, Andrea Wallenius, Birgitta Olanders at SwedPower AB Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	Intended user of the data are
General Purpose	The general purpose of the inventory was to obtain a lifecycle inventory of heat producing plants using different types of fuels. A further purpose was to obtain data from heat producing plants with different capacities.
Detailed Purpose	The specific purpose is to compare data from plants producing heat, with various fuels, combustion technologies and flue gas cleaning systems.
Commissioner	Bodlund, Birgit - Vattenfall AB.
Practitioner	- SwedPower AB, Maria Münter, Emanuel Nandorf, Pernilla Strömberg, Andrea Wallenius, Birgitta Olanders .
Reviewer	Pålsson, Ann-Christin - CPM Technical Environmental Planning Chalmers University of Technology 412 96 Göteborg
Applicability	CERTAIN CAUTIONS: This inventory was conducted using data mainly from 1996. The data consists of average data on a year basis. This data is assumed to be valid until new national or local regulations are enforced in Sweden. This data should only be used on plants producing heat in Sweden and for swedish conditions. When both heat and power are produced the allocation between the products are the same. That is the environmental load for 1 kWh produced heat are the same as for 1 kWh produced electrical power.
About Data	GENERAL DATA SOURCE DESCRIPTION: Data quality in the meaning good precision for the operation of the plant concerning for example the precision of emission measurements, calibration of instruments are good for plants larger than 10 MW and/or plants with a production larger than 25 GWh/year. These plants are included in the NOx control system . At these plants the instruments for NOx-control and calculations are controlled every year at the periodical inspection. Most larger plants are also calibrating other instruments in there own interest or as a consequence of an internal control program.
Notes	Combined heat and power are used as base primarily during the winter half, when the need for heat and power are the largest.

SPINE LCI dataset: ED95 - Sugar cane, cradle-to-gate, energy allocation, impact categories only - f3 fuels

Administrative	
Finished	Y
Date Completed	2013-11-30
Copyright	f3 - Swedish Knowledge Centre for Renewable Transportation Fuels
Availability	Public

Technical System	
Name	ED95 - Sugar cane, cradle-to-gate, energy allocation, impact categories only - f3 fuels
Functional Unit	1 MJ
Functional Unit Explanation	1 MJ output of ED95 fuel
Process Type	Cradle to gate
Site	

Sector	Fuel
Owner	
Technical system description	This dataset represents a model of the cradle to gate production of ED95 based on ethanol from sugar cane. The following processes are covered: - Cultivation of the sugar cane - Harvest - Distribution to the fuel plant - Production of ethanol - Transportation of ethanol from Brazil to a Swedish port Indirect land use change is considered not to occur, as there are no confirmed links under current situation (Berndes et al, 2010 in Börjesson et al 2010). Data in Börjesson et al. are only published as impact categories and not as emissions except for particles. The amount of primary energy is not mentioned either. A case with allocation is made in Börjesson et al. In the f3 fuels data project, data sets both with and without system expansion are published. ED95 is an ethanol based fuel used in diesel engines (trucks and buses). In Sweden ED95 is produced by SEKAB, Domsjö, Örnsköldsvik. The ethanol for ED95 can be produced from different raw materials such as wheat, sugar beet, sugar cane etc., but since last year (2012) SEKAB only purchases ethanol from Brazilian sugar canes, since it is considered to be the most sustainable . The composition of ED95 is 94 w-% denaturised hydrous ethanol and 6 w-% components. The components function are ignition improver, lubricant and denaturant. SEKAB (1) has provided the exact composition and chemical information about the components as well all relevant physical properties such as densities, heat values and fossil carbon contents. These data are however confidential. Two LCA models of the ED95 fuel was made; based on Brazilian sugar cane ethanol and based on ethanol from wheat. The models include the upstream production of the raw materials, but not the ED95 production itself. Since the composition is confidential, only the LCI-results from this model were published in the database. For the production of ethanol (cradle to gate) data from Börjesson 2010 (2) were used for both sugar cane and wheat ethanol. For each ethanol, a scenario with energy alloaction and system expansion are published. The ignition improver and lubricant are produced by AkzoNobel Surface Chemistry (3). They have LCA data for their production, but could not provide the data within the timeframes of the project. Instead data were found in a Master thesis performed for AkzoNobel Surface Chemistry (4). These data are from 2003 and were the most recent data available. Data for the denaturant were found in the EcoInvent database (5). The data were recalculated from per kg to per MJ of fuel by using a heat value of 25.7 MJ/kg (1). The following processes are covered: - Cultivation of the sugar cane - Harvest - Distribution to the fuel plant - Production of ethanol - Transportation of ethanol from Brazil to a Swedish port Indirect land use change is considered not to occur, as there are no confirmed links under current situation (Berndes et al, 2010 in Börjesson et al 2010). Data in Börjesson et al. are only published as impact categories and not as emissions except for particles. The amount of primary energy is not mentioned either. A case with allocation is made in Börjesson et al. In the f3 fuels data project, data sets both with and without system expansion are published.

Functional Unit	1 MJ
Functional Unit Explanation	1 MJ input of ED95 fuel to vehicle tank
Process Type	Gate to grave
Site	
Sector	Fuel
Owner	
Technical system description	The data represent emissions from ED95 combustion in a diesel engine in heavy duty truck or bus, Euro V, tank-to-wheel. The emission legislation uses the definition of a heavy duty vehicle having a gross weight of 3.5 tons or more. The reported emission factors should be considered as generic data, and it should be noted that the emissions for a specific vehicle and a specific mission might differ from those generic data. For example, the limit values for certification of engines have been used as basis for deriving some of the emission factors. The duty cycles used for certification are defined to cover the whole range of typical loads of an engine in different operations. The operation of a specific vehicle can however differ from the duty cycle used in the certification, resulting in different emissions than calculated with the generic emission factors. E.g. for the regulated emissions: nitrous oxides, particles, total organic compounds and carbon monoxide, the values are conservative based on the maximum emissions limits per kWh of engine output when driving at the best point (the optimal engine speed/torque operating point). In reality, the values are often lower.

Data Type	
Represents	N/A
Method	The emission factors (EF, kg/MJ) for the regulated emissions have been estimated based on ETC (transient test cycle for truck and bus engines), legislation limits for Euro V (2005/55/EC). The ETC cycle is for heavy duty engines and vehicle (www.dieselnet.com). Equation for calculation of emission factors for fuel use: Efficiency: 0.43 (?)= (energy work/energy in fuel) which is the efficiency at the best point (the optimal engine speed/torque operating point) for a diesel engine and which gives the maximum emission factors within the legislation limit. EF fuel use (g/MJ)=EF work (g/kWh)/3.6*? Emissions of CO2 and SO2 have been calculated based on carbon- and sulphur content in the fuel, see documentation "Data compilation method for a specific flow" and "Reference" in the Flow table. Emissions of CH4 was calculated from JRC (2013) and N2O was best estimate.
Literature Reference	Main references: (1) 2005/55/EC (2) www.dieselnet.com (3) JRC (2013) Tank-to-wheels, Report Version 4.0, JEC well -to-wheels analysis, well-to-wheels analysis of future automotive fuels and and powertrains in the European context, July 2013 (4) SEKAB, Roger Mattebo, personal communication 2013. (5) Dir 2009/30/EC
Notes	The parameters presented are chosen because they are available in the annual environmental report of the plant. Data can be missing if it is not reported in the report. The type of data reported is governed by the inspection authority. All values are reported with 3 figures. The data are however seldom that accurate.

SPINE LCI dataset: Electric freight train, waggon load

Administrative	
Finished	Y
Date Completed	99 - 11 -
Copyright	NTM
Availability	The data is publically available.

Technical System	
Name	Electric freight train, waggon load
Functional Unit	1 tonkm 46 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 46 %. An utilisation level of 46 % is representative for Swedish domestic traffic if *transportation of empty trucks are included.*
Process Type	Gate to gate
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of a waggon load freight train with an RC engine. Electrically driven waggon load freight train is the traditional freight train used in Sweden. Different types of waggons and aimed for different destinations are connected and pulled by one single engine. The waggons are connected and deconnected during the route to their final destinations. The operation includes: -Propulsion (including auxiliary machinery and safety systems) -Comfort during the journey -Complimentary runs -Stationary vehicle heating -Operation of fixed installations (not including heating of premises)

System Boundaries	
Nature Boundary	-Emissions to air have not been included. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.

Time Boundary	The data represents the fleet in 1999.
Geographical Boundary	The data is based on Swedish conditions
Other Boundaries	The average utilisation level is 46 %. The utilisation level includes transportation of empty trucks. Parameters not considered -Driving technique -Maintenance level of the engine -External conditions i.e. climate etc -Use of lubricating oil -Wear of brake lining, rail and wheel, areal line and collector shoe Excluded subsystems -Electricity production -Maintenence of the engine -Aftertreatement of the engine - Handling of production rests - Manufacturing of vehicles and other equipment - Heating of buildings serving the transportation system - Erection and maintenance of infrastructure
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1999 - 11
Data Type	Random samples
Represents	NTM
Method	The electricity consumption is based on measurements on 6000 freight trains in regular traffic conducted between 1994 and 1998 by the Department of Vehicle Engineering, Railway Technology, Royal Institute of Technology (KTH). The electricity consumption per tonkm was calculated using an load factor of 46%. The *quantity value* refers to an average of the energy use of the studied trains. The *minimum and maximum value* refers to the minimum and the maximum value obtained by the measurements. Current and voltage were measured in the trains tractive units (locomotive or motor coach), at the energy input close to the current collector. Additions were then made for losses in the railways supply system. The results thus obtained give electrical energy consumption per gross-tonne-km reckoned in power outtake from the national grid. The energy use was calculated per net-tonne-km as a function of the trains capacity and load factor. The losses in the railway supply system include losses in converters and catenary cables (efficiency 81,8% for supply to RC locomotives) and losses suffered in transmitting electricity from the power station to the feed-in point (the losses are assumed to be approx. 4 %) For further details see Andersson. The load factor that was used in the calculations is a representative mean value for different types of freight traffic, based on statistics from the State Railways Freight Transportation Division and State Railways Financial department. For the whole of State Railways Freight traffic, excluding iron-ore transport, the mean load factor was about 46% in 1993. (Load factor=net-tonne/gross-tonne where the gross-tonne concept refer to train weight, including locomotive freight wagons and load. The net-tonne concept refers to payload after the weight of the locomotive and wagons have been excluded.)
Literature Reference	Andersson, E., ''Energy consumption and air pollution of electric rail traffic, The Swedish case'', TRITA-FKT, Report 9446, Railway Technlogy, Department of Vehicle Engineering, Royal Institute of Technology, 1994.
Notes	The minimum and maximum value is caused by variations in external conditions (number of stops, topography, number of passings, the trains composition of trucks regarding aerodynamics, driving technique and climate)

About Inventory

Publication	www.ntm.a.se Data Documented by Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology

Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	Strömberg, Jonas - SJ Cargo Group, Stockholm .
Reviewer	
Applicability	The data should not be used for detailed studies of transportation activities. More detailed data is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to obtain information in these matters. Railway traffic generally handles transportation of large heavy goods over long distances. Both electrically driven and diesel driven trains may be used. Electrically driven trains transport 95 % of the goods handled by train. Each truck of the trains may be assumed to have a loading capacity with regard to weight of 55 tonnes and a maximum gross weight of 80 tonnes. The trains are normally marshalled. Electrically driven combi train consists of trucks loaded with load carriers that also may be loaded and transported by truck. The share of goods transported by combi trains are about 5 % of the total amount of goods transported by electrically driven trains. Electrically driven system trains are not recoupled on the way and always take the same route between two adresses. No marshalling is done, but a diesel engine may be used at the end points. The trains are generally fully loaded one way, and empty on the return trip, i.e. the utilisation level is about 50 % or higher. System trains ordinarily runs special transportation assignments for different types of industry. Diesel driven engines (T44) are mainly used for shunting and for regular traffic in sections where there is no aerial line. There are still some sections of the swedish railway system that are not electrified. SJ also uses smaller diesel engines (V5) for shunting. The V5 engine has a capacity of 400-500 tonnes gross weight and is not used for regular traffic. -- Marshalling -- The major part of the goods is marshalled at 6 main junctions where the goods are gathered and new trains are put together for new destinations. Shunting is generally done by diesel driven engines and is performed in two ways: -Hump shunting (vallväxling) -Fly shunting (planväxling) -- Distance -- The railway network and the fact that the goods generally are marshalled means that the goods not always travel the shortest route between two destinations. When using the data, the distance may thus be difficult to assess. The company carrying out the transport should be contacted to get an accurate estimate of the distance. SJ has developed an environmentl data software with a databas of distances between 70 different places, concidering the infrastructure. The database does however not give information on which lines that arenot electrified. -- Bulky goods --

	The data can be used for bulcy goods with the recalculation of the volume of the goods to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. -- Emissions from electricity production -- When using the data, the electricity production should be included, especially when comparing different modes of transportation. The emissions from electricity production can be calculated from the mix of electricity production processes that the electricity supplyers have that supplies SJ with electricity. SJ buys exclusivally ''ecolabelled'' electricity, i.e. hydro power with the following emission data (Brännström-Norberg et al., 1996): CO_2: 0,0677 (g/kWh electr.) NO_x: 0,000263 SO_2: 0,000109 CO: 0,0018 Particl.: 0,0000295 HC: 0,000247 NTM has agreed on this way of calculating if the supplyer and buyer have a contract. References: Brännström-Norberg B-M et al (1996). ''Livscykelanalys för Vattenfalls Elproduktion - Sammanfattande rapport'', Vattenfall, Stockholm
About Data	.***Electricity consumption*** The electricity consumption was obtained by energy studies of 6000 trains in regular traffic, including losses in the railway supply system. Several parameters thus influence the energy use, such as e.g. topography, driving technique, the number of starts and stops, number of passing, the trains composition of trucks regarding aerodynamics and the weight of the train etc. The electricity consumption is roughly proportional to the weight of the train. Consequently, the electricity consumption per tonkm for a given utilisation level is approximately constant, independent on the size of the train. ***Utilisation level*** For electrically driven goods trains, the data is based on an average utilisation level of 46 % (including transportation of empty trucks). The average utilisation level was based on statistics from 1993 from the Swedish State Railways. Today the average utilisation level is higher according to the Swedish State Railways due to different actions to use the trains more effectively. The utilisation level for a specific transport may vary. There are however no general rules regarding differences in the utilisation level, and what utilisation level to chose for a specific transport operation.
Notes	The person stated as ''Practitioner'' is the contact person for the data for transportation by train in NTM.Data is collected from NTM homepage, latest updated 1999 - 11 - 11. The data is continously updated and the user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: www.ntm.a.se The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation.Updated data for diesel trains and road transport are expected to be published before summer 2000. The major Swedish actors in the transportation business, which are members of NTM (e.g., SJ, BTL, ASG, etc.), will use the data as a basis for environmental assessment of different transportation alternatives.

SPINE LCI dataset: Electric freight train, waggon load, including electricity production

Availability	The data is publically available.

Technical System

Name	Electric freight train, waggon load, including electricity production
Functional Unit	1 tonkm 46 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 46 %. An utilisation level of 46 % is representative for Swedish domestic traffic if *transportation of empty trucks are included.*
Process Type	Gate to gate
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of a waggon load freight train with an RC engine, including production of electricity used in the transport. Electrically driven waggon load freight train is the traditional freight train used in Sweden. Different types of waggons and aimed for different destinations are connected and pulled by one single engine. The waggons are connected and deconnected during the route to their final destinations. The operation includes: -Propulsion (including auxiliary machinery and safety systems) -Comfort during the journey -Complimentary runs -Stationary vehicle heating -Operation of fixed installations (not including heating of premises) The production of electricity includes fuel production, operation and maintenance of hydro power. SJ buys exclusively ''ecolabelled'' electricity, i.e. hydro power.

System Boundaries

Nature Boundary	Regulated emissions to air are included. The parameters that are presented are: - Regulated emissions for diesel engines: NOx, HC, particles and CO - Fuel regulated: SO2 - Tax regulated CO2. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents the fleet in 1999
Geographical Boundary	The data is based on Swedish conditions
Other Boundaries	The average utilisation level is 46 %. The utilisation level includes transportation of empty trucks. Parameters not considered -Driving technique -Maintenance level of the engine -External conditions i.e. climate etc -Use of lubricating oil -Wear of brake lining, rail and wheel, areal line and collector shoe Excluded subsystems -Maintenence of the engine -Aftertreatement of the engine - Handling of production rests - Manufacturing of vehicles and other equipment - Heating of buildings serving the transportation system - Erection and maintenance of infrastructure

Flow Data

General Activity QMetaData

Date Conceived	1999 - 11
Data Type	Random samples
Represents	NTM
Method	The electricity consumption is based on measurements on 6000 freight trains in regular traffic conducted between 1994 and 1998 by the Department of Vehicle Engineering, Railway Technology, Royal Institute of Technology (KTH). The electricity consumption per tonkm was calculated using an load factor of 46%. The *quantity value* refers to an average

	of the energy use of the studied trains. The *minimum and maximum value* refers to the minimum and the maximum value obtained by the measurements. Current and voltage were measured in the trains tractive units (locomotive or motor coach), at the energy input close to the current collector. Additions were then made for losses in the railways supply system. The results thus obtained give electrical energy consumption per gross-tonne-km reckoned in power outtake from the national grid. The energy use was calculated per net-tonne-km as a function of the trains capacity and load factor. The losses in the railway supply system include losses in converters and catenary cables (efficiency 81,8% for supply to RC locomotives) and losses suffered in transmitting electricity from the power station to the feed-in point (the losses are assumed to be approx. 4 %) For further details see Andersson. The load factor that was used in the calculations is a representative mean value for different types of freight traffic, based on statistics from the State Railways Freight Transportation Division and State Railways Financial department. For the whole of State Railways Freight traffic, excluding iron-ore transport, the mean load factor was about 46% in 1993. (Load factor=net-tonne/gross-tonne where the gross-tonne concept refer to train weight, including locomotive freight wagons and load. The net-tonne concept refers to payload after the weight of the locomotive and wagons have been excluded.) ***Emissions from electricity production*** The emissions from electricity production are calculated after the mix of electricity production processes that the electricity supplyers have that supplies SJ with electricity. SJ buys exclusivally ''ecolabelled'' electricity, i.e. hydro power. The with the following emission factors have been used (Brännström-Norberg et al., 1996): CO2: 0,0677 (g/kWh electr.) NOx: 0,000263 SO2: 0,000109 CO: 0,0018 Particl.: 0,0000295 HC: 0,000247 NTM has agreed on this way of calculating if the supplier and buyer have a contract.
Literature Reference	Brännström-Norberg B-M., et al, Livscykelanalys för Vattenfalls elproduktion Sammanfattande rapport, Vattenfall, 1996. Buhre M., Eriksson Å., Livscykelanalys för kolkraft, Linköping Institute of Technology and Uppsala University, 1997 Andersson, E., ''Energy consumption and air pollution of electric rail traffic, The Swedish case'', TRITA-FKT, Report 9446, Railway Technlogy, Department of Vehicle Engineering, Royal Institute of Technology, 1994.
Notes	The minimum and maximum value for the electricity consumption is caused by variations in external conditions (number of stops, topography, number of passings, the trains composition of trucks regarding aerodynamics, driving technique and climate)

About Inventory

Publication	www.ntm.a.se Data Documented by Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation

Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation) The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NTM.
Practitioner	Strömberg, Jonas - SJ Cargo Group, Stockholm .

Applicability	The data should not be used for detailed studies of transportation activities. More detailed data is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to obtain information in these matters. Railway traffic generally handles transportation of large heavy goods over long distances. Both electrically driven and diesel driven trains may be used. Electrically driven trains transport 95 % of the goods handled by train. Each truck of the trains may be assumed to have a loading capacity with regard to weight of 55 tonnes and a maximum gross weight of 80 tonnes. The trains are normally marshalled. Electrically driven combi train consists of trucks loaded with load carriers that also may be loaded and transported by truck. The share of goods transported by combi trains are about 5 % of the total amount of goods transported by electrically driven trains. Electyrically driven system trains are not recoupled on the way and always take the same route between two adresses. No marshalling is done, but a diesel engine may be used at the end points. The trains are generally fully loaded one way, and empty on the return trip, i.e. the utilisation level is about 50 % or higher. System trains ordinarily runs special transportation assignments for different types of industry. Diesel driven engines (T44) are mainly used for shunting and for regular traffic in sections where there is no aerial line. There are still some sections of the swedish railway system that are not electrified. SJ also uses smaller diesel engines (V5) for shunting. The V5 engine has a capacity of 400-500 tonnes gross weight and is not used for regular traffic. -- Marshalling -- The major part of the goods is marshalled at 6 main junctions where the goods are gathered and new trains are put together for new destinations. Shunting is generally done by diesel driven engines and is performed in two ways: -Hump shunting (valväxling) -Fly shunting (planväxling) -- Distance -- The railway network and the fact that the goods generally are marshalled means that the goods not always travel the shortest route between two destinations. When using the data, the distance may thus be difficult to assess. The company carrying out the transport should be contacted to get an accurate estimate of the distance. SJ has developed an environmentl data software with a databas of distances between 70 different places, concidering the infrastructure. The database does however not give information on which lines that arenot electrified. -- Bulky goods -- The data can be used for bulcy goods with the recalculation of the volume of the goods to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.
About Data	.***Electricity consumption*** The electricity consumption was obtained by energy studies of 6000 trains in regular traffic, including losses in the railway supply system. Several parameters thus influence the energy use, such as e.g. topography, driving technique, the number of starts and stops, number of passing, the trains composition of trucks regarding aerodynamics and the weight of the train etc. The electricity consumption is roughly proportional to the weight of the train. Consequently, the electricity consumption per tonkm for a given utilisation level is approximately constant, independent on the size of the train. ***Utilisation level*** For electrically driven goods trains, the data is based on an average utilisation level of 46 % (including transportation of empty trucks). The average utilisation level was based on statistics from 1993 from the Swedish State Railways. Today the average utilisation level is higher according to the Swedish State Railways due to different actions to use the trains more effectively.

	The utilisation level for a specific transport may vary. There are however no general rules regarding differences in the utilisation level, and what utilisation level to chose for a specific transport operation. ***Emissions from electricity production*** The emissions from electricity production are calculated from the mix of electricity production processes that the electricity supplyers have that supplies SJ with electricity. SJ buys exclusivally ''ecolabelled'' electricity, i.e. hydro power. The following emission data has been used (Brännström-Norberg et al., 1996): CO2: 0,0677 (g/kWh electr.) NOx: 0,000263 SO2: 0,000109 CO: 0,0018 Particl.: 0,0000295 HC: 0,000247 NTM has agreed on this way of calculating if the supplyer and buyer have a contract.
Notes	The person stated as ''Practitioner'' is the contact person for the data for transportation by train in NTM. Data is collected from NTM homepage, latest updated 1999 - 11 - 11. The data is continously updated and the user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: www.ntm.a.se The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation.Updated data for diesel trains and road transport are expected to be published before summer 2000. The major Swedish actors in the transportation business, which are members of NTM (e.g., SJ, BTL, ASG, etc.), will use the data as a basis for environmental assessment of different transportation alternatives.

SPINE LCI dataset: Electrically driven combi train, future

Technical System	
Name	Electrically driven combi train, future
Functional Unit	1 tonkm, 46 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 46 %. An utilisation level of 46 % is representative for Swedish domestic traffic if *transportation of empty trucks are included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation, i.e. propulsion of an electrically driven combi train, assuming different energy saving measures on the existing system (rebuilding trains). The aim is to get a picture of future energy use of electric train traffic. Electrically driven combi train consists of trucks loaded with load carriers that also may be loaded and transported by truck.

System Boundaries

Nature Boundary	Diffuse emissions to air and emissions to water and ground, noise, encroachment and other environmental impacts have not been considered.
Time Boundary	The data represents an assessment of future energy use and emissions of electric train traffic.
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 46 %. The utilisation level includes transportation of empty trucks. *Parameters not considered* -Driving technique -Maintenance level of the engine -External conditions i.e. climate etc. -Use of lubricating oil -Wear of brake lining, rail and wheel, aerial line and collector shoe *Excluded subsystems* -Electricity production -Maintenance of the engine -After-treatment of the engine -Handling of production rests -Manufacturing of vehicles and other equipment -Heating of buildings serving the transportation system -Erection and maintenance of infrastructure
Allocations	N/A

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The electricity consumption was calculated using the assumption that the energy use may be reduced by 35 % by new engines and rebuilding existing engines together with data for existing trains in regular traffic with the lowest energy use. The assumption was based on Andersson. The electricity consumption per tonkm was calculated using an load factor of 46%. The data for trains in use in regular traffic today can be found in the activity ObjectOfStudy.Name: Electrically driven goods train 700 metres, RC engine (in this database)or in NGM. The minimum value for the energy use was used in the calculation. The data is based on measurements on freight trains in regular traffic conducted between 1994 and 1997 by the Department of Vehicle Engineering, Railway Technology, Royal Institute of Technology (KTH). The data includes losses in the railway supply system.
Literature Reference	Andersson, E., 'Future Energy Consumption of the Railways' (in Swedish), TRITA-FKT 1996:49, Railway Technology, Department of Vehicle Engineering, Royal Institute of Technology, 1994. Applicability	The ambition with the data was to get a picture of future energy use and emissions for Swedish train traffic. The data represents best available technology not yet in use.
About Data	***Electricity consumption*** The electricity consumption was based on assumptions that the energy use in the existing system may be reduced by 35% by different energy saving measures, rebuilding existing engines and new engines. ***Emissions from electricity production*** When using the data, the electricity production should be included, especially when comparing different modes of transportation. SJ and NGM propose that the following data for average Swedish electricity production should be used to calculate the emissions from electricity production: -NOx: 0,038 g/kWh produced electricity -S: 0,021 g/kWh produced electricity -CO: 0,023 g/kWh produced electricity -HC: 0,0003 g/kWh produced electricity -CO2: 20,8 g/kWh produced electricity The data was given by Vattenfall AB and concern the Swedish electricity production in 1993. The following production methods were used: Hydro-electric power (52%), Nuclear power (42%), Wind power (0,04%), Thermal power (6%) where 2% is fuelled by fossil fuels. Today, SJ buys electricity from Vattenfall and Tälje energi
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to obtain information on how the goods are handled and the transport is carried out. Railway traffic generally handles transportation of large heavy goods over long distances. Both electrically driven and diesel driven trains may be used: *Electrically driven freight trains* transport 95 % of the goods handled by train. Each truck of the trains may be assumed to have a loading capacity with regard to weight of 55 tonnes and a maximum gross weight of 80 tonnes. The trains are normally marshalled. *Electrically driven combi train* consists of trucks loaded with load carriers that also may be loaded and transported by truck. The share of goods transportation by combi train is about 5 % of the total transportation by electrically driven goods trains. *Electrically driven system trains* are not recoupled on the way and always take the same route between two addresses. No marshalling is done, but a diesel engine may be used at the end points. The trains are generally fully loaded one way, and empty on the return trip, i.e. the utilisation level is 50% or higher. System trains ordinarily runs special transportation assignments for different types of industry. *Diesel driven engines* (T44) are mainly used for shunting and for regular traffic in sections where there is no aerial line. There are still some sections of the Swedish railway system that are not electrified. SJ also uses a smaller diesel driven engine (V5) for shunting. The V5 engine has a capacity of 450-500 tonnes gross weight and is not ordinarily used for regular traffic. ***Marshalling*** The major part of the goods is marshalled at 6 main junctions were the goods are gathered and new trains are put together for new destinations. Shunting is generally done by diesel driven engines and is performed in two ways: -Hump shunting (vallväxling) -Fly shunting (planväxling) ***Distance*** The railway network and the fact that the goods generally are marshalled means that the goods not always travel the shortest route between two destinations. When using the data, the distance may thus be difficult to assess. The company carrying out the transport should be contacted to get an accurate estimate of the distance. SJ (Swedish State Railways) has developed environmental data software with a database of distances between 70 different places, considering the infrastructure. The database does however not give information on which lines that are not electrified. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume of the goods to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***International train traffic*** The data for the electricity consumption use may be used for train transports in Europe, since the technique in other countries are similar (electrically and diesel driven engines). The handling of the goods may however differ in different countries, e.g. regarding average utilisation level etc. Also, the electricity production in different countries varies.
About Data	***Electricity consumption*** The electricity consumption was obtained by energy studies of 6000 trains in regular traffic, including losses in the railway supply system. Several parameters thus influence the energy use, such as e.g. topography, driving technique, the number of starts and stops, number of passing, the trains composition of trucks regarding aerodynamics and the weight of the train etc. The electricity consumption is roughly proportional to the weight of the train. Consequently, the electricity consumption per tonkm for a given utilisation level is approximately constant, independent on the size of the train. ***Utilisation level*** For electrically driven goods trains, the data is based on an average utilisation level of 46 % (including transportation of empty trucks). The average utilisation level was based on statistics from 1993 from the Swedish State Railways. Today the average utilisation level is higher according to the Swedish State Railways due to different actions to use the trains

	more effectively. The utilisation level for a specific transport may vary. There are however no general rules regarding differences in the utilisation level, and what utilisation level to chose for a specific transport operation. ***Emissions from electricity production*** When using the data, the electricity production should be included, especially when comparing different modes of transportation. SJ and NGM propose that the following data for average Swedish electricity production should be used to calculate the emissions from electricity production: -NOx: 0,038 g/kWh produced electricity -S: 0,021 g/kWh produced electricity -CO: 0,023 g/kWh produced electricity -HC: 0,0003 g/kWh produced electricity -CO2: 20,8 g/kWh produced electricity The data was given by Vattenfall AB and concern the Swedish electricity production in 1993. The following production methods were used: Hydro-electric power (52%), Nuclear power (42%), Wind power (0,04%), Thermal power (6%) where 2% is fuelled by fossil fuels. Today, SJ buys electricity from Vattenfall and Tälje energi.
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Electrically driven freight train 230 metres, future

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Electrically driven freight train 230 metres, future
Functional Unit	1 tonkm, 46 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 46 %. An utilisation level of 46 % is representative for Swedish domestic traffic if *transportation of empty trucks are included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden

Technical system description	Operation, i.e. propulsion of an electrically driven freight train, 230 metres, assuming different energy saving measures on the existing system (rebuilding trains etc.). The aim is to get a picture of future energy use of electric train traffic. Electrically driven freight trains transport 95 % of the goods handled by train. Each truck of the trains may be assumed to have a loading capacity with regard to weight of 55 tonnes and a maximum gross weight of 80 tonnes.

System Boundaries

Nature Boundary	Diffuse emissions to air and emissions to water and ground, noise, encroachment and other environmental impacts have not been considered.
Time Boundary	The data represents an assessment of future energy use and emissions of electric train traffic.
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 46 %. The utilisation level includes transportation of empty trucks. *Parameters not considered* -Driving technique -Maintenance level of the engine -External conditions i.e. climate etc. -Use of lubricating oil -Wear of brake lining, rail and wheel, aerial line and collector shoe *Excluded subsystems* -Electricity production -Maintenance of the engine -After-treatment of the engine -Handling of production rests -Manufacturing of vehicles and other equipment -Heating of buildings serving the transportation system -Erection and maintenance of infrastructure
Allocations	
Systems Expansions	

Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The electricity consumption was calculated using the assumption that the energy use may be reduced by 35 % by new engines and rebuilding existing engines together with data for existing trains in regular traffic with the lowest energy use. The assumption was based on Andersson. The electricity consumption per tonkm was calculated using an load factor of 46%. The data for trains in use in regular traffic today can be found in the activity ObjectOfStudy.Name: Electrically driven goods train 700 metres, RC engine (in this database)or in NGM. The minimum value for the energy use was used in the calculation. The data is based on measurements on freight trains in regular traffic conducted between 1994 and 1997 by the Department of Vehicle Engineering, Railway Technology, Royal Institute of Technology (KTH). The data includes losses in the railway supply system.
Literature Reference	Andersson, E., 'Future Energy Consumption of the Railways' (in Swedish), TRITA-FKT 1996:49, Railway Technology, Department of Vehicle Engineering, Royal Institute of Technology, 1994. NGM (Nätverket för Godstransporter och Miljön) Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997, NGM, (In Swedish) 1997
Notes	The minimum and maximum value is caused by variations in external conditions (number of stops, topography, number of passings, the trains composition of trucks regarding aerodynamics, driving technique and climate)

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Ingela Melkersson, SJ Stab Information, contact person for rail transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Trouve, Johan - SJ (Swedish State Railways), Stab Information, Box 1522, 401 50 Göteborg.
Reviewer	
Applicability	The ambition with the data was to get a picture of future energy use and emissions for Swedish train traffic. The data represents new technology not yet in use.
About Data	***Electricity consumption*** The electricity consumption was based on assumptions that the energy use in the existing system may be reduced by 35% by different energy saving measures, rebuilding existing engines and new engines. ***Emissions from electricity production*** When using the data, the electricity production should be included, especially when comparing different modes of transportation. SJ and NGM propose that the following data for average Swedish electricity production should be used to calculate the emissions from electricity production: -NOx: 0,038 g/kWh produced electricity -S: 0,021 g/kWh produced electricity -CO: 0,023 g/kWh produced electricity -HC: 0,0003 g/kWh produced electricity -CO2: 20,8 g/kWh produced electricity The data was given by Vattenfall AB and concern the Swedish electricity production in 1993. The following production methods were used: Hydro-electric power (52%), Nuclear power (42%), Wind power (0,04%), Thermal power (6%) where 2% is fuelled by fossil fuels. Today, SJ buys electricity from Vattenfall and Tälje energi.
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different

	transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

Flow Data

General Activity QMetaData

Date Conceived	1994-01-01 - 1997-01-01
Data Type	Random samples
Represents	NTM
Method	The electricity consumption is based on measurements on 6000 freight trains in regular traffic conducted between 1994 and 1997 by the Department of Vehicle Engineering, Railway Technology, Royal Institute of Technology (KTH). The electricity consumption per tonkm was calculated using an load factor of 46%. The *quantity value* refers to an average of the energy use of the studied trains. The *minimum and maximum value* refers to the minimum and the maximum value obtained by the measurements. Current and voltage were measured in the trains tractive units (locomotive or motor coach), at the energy input close to the current collector. Additions were then made for losses in the railways supply system. The results thus obtained give electrical energy consumption per gross-tonne-km reckoned in power outtake from the national grid. The energy use was calculated per net-tonne-km as a function of the trains capacity and load factor. The losses in the railway supply system include losses in converters and catenary cables (efficiency 81,8% for supply to RC locomotives) and losses suffered in transmitting electricity from the power station to the feed-in point (the losses are assumed to be approx. 4 %) For further details see Andersson. The load factor that was used in the calculations is a representative mean value for different types of freight traffic, based on statistics from the State Railways Freight Transportation Division and State Railways Financial department. For the whole of State Railways Freight traffic, excluding iron-ore transport, the mean load factor was about 46% in 1993. (Load factor=net-tonne/gross-tonne where the gross-tonne concept refer to train weight, including locomotive freight wagons and load. The net-tonne concept refers to payload after the weight of the locomotive and wagons have been excluded).
Literature Reference	Andersson, E., ''Energy consumption and air pollution of electric rail traffic, The Swedish case'', TRITA-FKT, Report 9446, Railway Technlogy, Department of Vehicle Engineering, Royal Institute of Technology, 1994.
Notes	The minimum and maximum value is caused by variations in external conditions (number of stops, topography, number of passings, the trains composition of trucks regarding aerodynamics, driving technique and climate)

Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to obtain information on how the goods are handled and the transport is carried out. Railway traffic generally handles transportation of large heavy goods over long distances. Both electrically driven and diesel driven trains may be used: *Electrically driven freight trains* transport 95 % of the goods handled by train. Each truck of the trains may be assumed to have a loading capacity with regard to weight of 55 tonnes and a maximum gross weight of 80 tonnes. The trains are normally marshalled. *Electrically driven combi train* consists of trucks loaded with load carriers that also may be loaded and transported by truck. The share of goods transportation by combi train is about 5 % of the total transportation by electrically driven goods trains. *Electrically driven system trains* are not recoupled on the way and always take the same route between two addresses. No marshalling is done, but a diesel engine may be used at the end points. The trains are generally fully loaded one way, and empty on the return trip, i.e. the utilisation level is 50% or higher. System trains ordinarily runs special transportation assignments for different types of industry. *Diesel driven engines* (T44) are mainly used for shunting and for regular traffic in sections where there is no aerial line. There are still some sections of the Swedish railway system that are not electrified. SJ also uses a smaller diesel driven engine (V5) for shunting. The V5 engine has a capacity of 450-500 tonnes gross weight and is not ordinarily used for regular traffic. ***Marshalling*** The major part of the goods is marshalled at 6 main junctions were the goods are gathered and new trains are put together for new destinations. Shunting is generally done by diesel driven engines and is performed in two ways: -Hump shunting (vallväxling) -Fly shunting (planväxling) ***Distance*** The railway network and the fact that the goods generally are marshalled means that the goods not always travel the shortest route between two destinations. When using the data, the distance may thus be difficult to assess. The company carrying out the transport should be contacted to get an accurate estimate of the distance. SJ (Swedish State Railways) has developed environmental data software with a database of distances between 70 different places, considering the infrastructure. The database does however not give information on which lines that are not electrified. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume of the goods to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***International train traffic*** The data for the electricity use may be used for train transports in Europe, since the technique in other countries are similar (electrically and diesel driven engines). The handling of the goods may however differ in different countries, e.g. regarding average utilisation level etc. Also, the electricity production in different countries varies.

About Data	The electricity consumption was obtained by energy studies of 6000 trains in regular traffic, including losses in the railway supply system. Several parameters thus influence the energy use, such as e.g. topography, driving technique, the number of starts and stops, number of passing, the trains composition of trucks regarding aerodynamics and the weight of the train etc. The electricity consumption is roughly proportional to the weight of the train. Consequently, the electricity consumption per tonkm for a given utilisation level is approximately constant, independent on the size of the train. ***Utilisation level*** For electrically driven goods trains, the data is based on an average utilisation level of 46 % (including transportation of empty trucks). The average utilisation level was based on statistics from 1993 from the Swedish State Railways. Today the average utilisation level is higher according to the Swedish State Railways due to different actions to use the trains more effectively. The utilisation level for a specific transport may vary. There are however no general rules regarding differences in the utilisation level, and what utilisation level to chose for a specific transport operation. ***Emissions from electricity production*** When using the data, the electricity production should be included, especially when comparing different modes of transportation. SJ and NGM propose that the following data for average Swedish electricity production should be used to calculate the emissions from electricity production: -NOx: 0,038 g/kWh produced electricity -S: 0,021 g/kWh produced electricity -CO: 0,023 g/kWh produced electricity -HC: 0,0003 g/kWh produced electricity -CO2: 20,8 g/kWh produced electricity The data was given by Vattenfall AB and concern the Swedish electricity production in 1993. The following production methods were used: Hydro-electric power (52%), Nuclear power (42%), Wind power (0,04%), Thermal power (6%) where 2% is fuelled by fossil fuels. Today, SJ buys electricity Vattenfall and Tälje energi.

Flow Data

General Activity QMetaData

Date Conceived	1994-01-01 - 1997-01-01
Data Type	Random samples
Represents	NTM
Method	The electricity consumption is based on measurements on 6000 freight trains in regular traffic conducted between 1994 and 1997 by the Department of Vehicle Engineering, Railway Technology, Royal Institute of Technology (KTH). The electricity consumption per tonkm was calculated using an load factor of 46%. The *quantity value* refers to an average of the energy use of the studied trains. The *minimum and maximum value* refers to the minimum and the maximum value obtained by the measurements. Current and voltage were measured in the trains tractive units (locomotive or motor coach), at the energy input close to the current collector. Additions were then made for losses in the railways supply system. The results thus obtained give electrical energy consumption per gross-tonne-km reckoned in power outtake from the national grid. The energy use was calculated per net-tonne-km as a function of the trains capacity and load factor. The losses in the railway supply system include losses in converters and catenary cables (efficiency 81,8% for supply to RC locomotives) and losses suffered in transmitting electricity from the power station to the feed-in point (the losses are assumed to be approx. 4 %) For further details see Andersson. The load factor that was used in the calculations is a representative mean value for different types of freight traffic, based on statistics from the State Railways Freight Transportation Division and State Railways Financial department. For the whole of State Railways Freight traffic, excluding iron-ore transport, the mean load factor was about 46% in 1993. (Load factor=net-tonne/gross-tonne where the gross-tonne concept refer to train weight, including locomotive freight wagons and load. The net-tonne concept refers to payload after the weight of the locomotive and wagons have been excluded.)
Literature Reference	Andersson, E., ''Energy consumption and air pollution of electric rail traffic, The Swedish case'', TRITA-FKT, Report 9446, Railway Technlogy, Department of Vehicle Engineering, Royal Institute of Technology, 1994.
Notes	The minimum and maximum value is caused by variations in external conditions (number of stops, topography, number of passings, the trains composition of trucks regarding aerodynamics, driving technique and climate)

About Inventory

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997

	-- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Ingela Melkersson, SJ Stab Information, contact person for rail transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Trouve, Johan - SJ (Swedish State Railways), Stab Information, Box 1522, 401 50 Göteborg.

Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to obtain information on how the goods are handled and the transport is carried out. Railway traffic generally handles transportation of large heavy goods over long distances. Both electrically driven and diesel driven trains may be used: *Electrically driven freight trains* transport 95 % of the goods handled by train. Each truck of the trains may be assumed to have a loading capacity with regard to weight of 55 tonnes and a maximum gross weight of 80 tonnes. The trains are normally marshalled. *Electrically driven combi train* consists of trucks loaded with load carriers that also may be loaded and transported by truck. The share of goods transportation by combi train is about 5 % of the total transportation by electrically driven goods trains. *Electrically driven system trains* are not recoupled on the way and always take the same route between two addresses. No marshalling is done, but a diesel engine may be used at the end points. The trains are generally fully loaded one way, and empty on the return trip, i.e. the utilisation level is 50% or higher. System trains ordinarily runs special transportation assignments for different types of industry. *Diesel driven engines* (T44) are mainly used for shunting and for regular traffic in sections where there is no aerial line. There are still some sections of the Swedish railway system that are not electrified. SJ also uses a smaller diesel driven engine (V5) for shunting. The V5 engine has a capacity of 450-500 tonnes gross weight and is not ordinarily used for regular traffic. ***Marshalling*** The major part of the goods is marshalled at 6 main junctions were the goods are gathered and new trains are put together for new destinations. Shunting is generally done by diesel driven engines and is performed in two ways: -Hump shunting (vallväxling) -Fly shunting (planväxling) ***Distance*** The railway network and the fact that the goods generally are marshalled means that the goods not always travel the shortest route between two destinations. When using the data, the distance may thus be difficult to assess. The company carrying out the transport should be contacted to get an accurate estimate of the distance. SJ (Swedish State Railways) has

	developed environmental data software with a database of distances between 70 different places, considering the infrastructure. The database does however not give information on which lines that are not electrified. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume of the goods to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***International train traffic*** The data for the energy use may be used for train transports in Europe, since the technique in other countries are similar (electrically and diesel driven engines). The handling of the goods may however differ in different countries, e.g. regarding average utilisation level etc. Also, the electricity production in different countries varies.
About Data	***Electricity consumption*** The electricity consumption was obtained by energy studies of 6000 trains in regular traffic, including losses in the railway supply system. Several parameters thus influence the energy use, such as e.g. topography, driving technique, the number of starts and stops, number of passing, the trains composition of trucks regarding aerodynamics and the weight of the train etc. The electricity consumption is roughly proportional to the weight of the train. Consequently, the electricity consumption per tonkm for a given utilisation level is approximately constant, independent on the size of the train. ***Utilisation level*** For electrically driven goods trains, the data is based on an average utilisation level of 46 % (including transportation of empty trucks). The average utilisation level was based on statistics from 1993 from the Swedish State Railways. Today the average utilisation level is higher according to the Swedish State Railways due to different actions to use the trains more effectively. The utilisation level for a specific transport may vary. There are however no general rules regarding differences in the utilisation level, and what utilisation level to chose for a specific transport operation. ***Emissions from electricity production*** When using the data, the electricity production should be included, especially when comparing different modes of transportation. SJ and NGM propose that the following data for average Swedish electricity production should be used to calculate the emissions from electricity production: -NOx: 0,038 g/kWh produced electricity -S: 0,021 g/kWh produced electricity -CO: 0,023 g/kWh produced electricity -HC: 0,0003 g/kWh produced electricity -CO2: 20,8 g/kWh produced electricity The data was given by Vattenfall AB and concern the Swedish electricity production in 1993. The following production methods were used: Hydro-electric power (52%), Nuclear power (42%), Wind power (0,04%), Thermal power (6%) where 2% is fuelled by fossil fuels. Today, SJ buys electricity from Vattenfall and Tälje energi.
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Electrically driven Intermodal train, RC engine

Administrative

Finished	Y
Date Completed	99 - 11 -
Copyright	NTM
Availability	The data is publically available.

Technical System

Name	Electrically driven Intermodal train, RC engine
Functional Unit	1 tonkm 46 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 46 %. An utilisation level of 46 % is representative for Swedish domestic traffic if *transportation of empty trucks are included.*
Process Type	Gate to gate
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of a combi train with an RC engine. Electrically driven combi train consists of trucks loaded with load carriers that also may be loaded and transported by truck. The operation includes: -Propulsion (including auxiliary machinery and safety systems) -Comfort during the journey -Complimentary runs -Stationary vehicle heating -Operation of fixed installations (not including heating of premises) Maximum gross weight of the train: 1500 tonnes. Maximum loading capacity with regard to weight: 1031 tonnes.

System Boundaries

Nature Boundary	-Emissions to air have not been included. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents the fleet in 1999.
Geographical Boundary	The data is based on Swedish conditions
Other Boundaries	The average utilisation level is 46 %. The utilisation level includes transportation of empty trucks. Parameters not considered -Driving technique -Maintenance level of the engine -External conditions i.e. climate etc -Use of lubricating oil -Wear of brake lining, rail and wheel, areal line and collector shoe Excluded subsystems -Electricity production -Maintenence of the engine -Aftertreatement of the engine - Handling of production rests - Manufacturing of vehicles and other equipment - Heating of buildings serving the transportation system - Erection and maintenance of infrastructure

Electrically driven combi train consists of trucks loaded with load carriers that also may be loaded and transported by truck. The share of goods transported by combi trains are about 5 % of the total amount of goods transported by electrically driven trains. Electyrically driven system trains are not recoupled on the way and always take the same route between two adresses. No marshalling is done, but a diesel engine may be used at the end points. The trains are generally fully loaded one way, and empty on the return trip,

	i.e. the utilisation level is about 50 % or higher. System trains ordinarily runs special transportation assignments for different types of industry. Diesel driven engines (T44) are mainly used for shunting and for regular traffic in sections where there is no aerial line. There are still some sections of the swedish railway system that are not electrified. SJ also uses smaller diesel engines (V5) for shunting. The V5 engine has a capacity of 400-500 tonnes gross weight and is not used for regular traffic. -- Marshalling -- The major part of the goods is marshalled at 6 main junctions where the goods are gathered and new trains are put together for new destinations. Shunting is generally done by diesel driven engines and is performed in two ways: -Hump shunting (valväxling) -Fly shunting (planväxling) -- Distance -- The railway network and the fact that the goods generally are marshalled means that the goods not always travel the shortest route between two destinations. When using the data, the distance may thus be difficult to assess. The company carrying out the transport should be contacted to get an accurate estimate of the distance. SJ has developed an environmentl data software with a databas of distances between 70 different places, concidering the infrastructure. The database does however not give information on which lines that arenot electrified. -- Bulky goods -- The data can be used for bulcy goods with the recalculation of the volume of the goods to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business.
About Data	.***Electricity consumption*** The electricity consumption was obtained by energy studies of 6000 trains in regular traffic, including losses in the railway supply system. Several parameters thus influence the energy use, such as e.g. topography, driving technique, the number of starts and stops, number of passing, the trains composition of trucks regarding aerodynamics and the weight of the train etc. The electricity consumption is roughly proportional to the weight of the train. Consequently, the electricity consumption per tonkm for a given utilisation level is approximately constant, independent on the size of the train. ***Utilisation level*** For electrically driven goods trains, the data is based on an average utilisation level of 46 % (including transportation of empty trucks). The average utilisation level was based on statistics from 1993 from the Swedish State Railways. Today the average utilisation level is higher according to the Swedish State Railways due to different actions to use the trains more effectively. The utilisation level for a specific transport may vary. There are however no general rules regarding differences in the utilisation level, and what utilisation level to chose for a specific transport operation. ***Emissions from electricity production*** When using the data, the electricity production should be included, especially when comparing different modes of transportation. The emissions from electricity production are calculated after the mix of electricity production processes that the electricity supplyers have that supplies SJ with electricity. SJ buys exclusivally ''ecolabelled'' electricity, i.e. hydro power with the following emission data (Brännström-Norberg et al., 1996): CO2: 0,0677 (g/kWh electr.) NOx: 0,000263 SO2: 0,000109 CO: 0,0018 Particl.: 0,0000295 HC: 0,000247 NTM has agreed on this way of calculating if the supplyer and buyer have a contract.
Notes	The person stated as ''Practitioner'' is the contact person for the data for transportation by train in NTM. Data is collected from NTM homepage, latest updated 1999 - 11 - 11. The data is continously updated and the user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: www.ntm.a.se The work within NTM will continue to further increase the knowledge of different environmental interventions associated with goods transportation.Updated data for diesel trains and road transport are expected to be published before summer 2000. The major Swedish actors in the transportation business, which are members of NTM (e.g., SJ, BTL, ASG, etc.), will use the data as a basis for environmental assessment of different transportation alternatives.

SPINE LCI dataset: Electrically driven system train (Circuit-working), RC engine

Technical System	
Name	Electrically driven system train (Circuit-working), RC engine
Functional Unit	1 tonkm, 46 %
Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 46 %. An utilisation level of 46 % is representative for Swedish domestic traffic if *transportation of empty trucks are included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of an electrically driven system train, driven by an RC engine. Electrically driven system trains are not recoupled on the way and always take the same route between two addresses. No marshalling is done, but a diesel engine may be used at the end points. System trains ordinarily runs special transportation assignments for different types of industry The operation includes -Propulsion (including auxiliary machinery and safety systems) -Comfort during the journey -Complimentary runs -Stationary vehicle heating -Operation of fixed installations (not including heating of premises) Maximum gross weight of the train: 1500 tonnes. Maximum loading capacity with regard to weight: 1031 tonnes.

System Boundaries	
Nature Boundary	-Emissions to air have not been included. Diffuse emissions to air, emissions to water and ground, noise, encroachment and other environmental loads have not been considered.
Time Boundary	The data represents the fleet in 1999
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 46 %. The utilisation level includes transportation of empty trucks. *Parameters not considered* -Driving technique -Maintenance level of the engine -External conditions i.e. climate etc. -Use of lubricating oil -Wear of brake lining, rail and wheel, aerial line and collector shoe *Excluded subsystems* -Electricity production -Maintenance of the engine -After-treatment of the engine -Handling of production rests -Manufacturing of vehicles and other equipment -Heating of buildings serving the transportation system -Erection and maintenance of infrastructure
Allocations	N/A

Flow Data

General Activity QMetaData

Date Conceived	1999 - 11
Data Type	Random samples
Represents	NTM
Method	The electricity consumption is based on measurements on 6000 freight trains in regular traffic conducted between 1994 and 1997 by the Department of Vehicle Engineering, Railway Technology, Royal Institute of Technology (KTH). The electricity consumption per tonkm was calculated using an load factor of 46%. The *quantity value* refers to an average of the energy use of the studied trains. The *minimum and maximum value* refers to the minimum and the maximum value obtained by the measurements. Current and voltage were measured in the trains tractive units (locomotive or motor coach), at the energy input close to the current collector. Additions were then made for losses in the railways supply system. The results thus obtained give electrical energy consumption per gross-tonne-km reckoned in power outtake from the national grid. The energy use was calculated per net-tonne-km as a function of the trains capacity and load factor. The losses in the railway supply system include losses in converters and catenary cables (efficiency 81,8% for supply to RC locomotives) and losses suffered in transmitting electricity from the power station to the feed-in point (the losses are assumed to be approx. 4 %) For further details see Andersson. The load factor that was used in the calculations is a representative mean value for different types of freight traffic, based on statistics from the State Railways Freight Transportation Division and State Railways Financial department. For the whole of State Railways Freight traffic, excluding iron-ore transport, the mean load factor was about 46% in 1993. (Load factor=net-tonne/gross-tonne where the gross-tonne concept refer to train weight, including locomotive freight wagons and load. The net-tonne concept refers to payload after the weight of the locomotive and wagons have been excluded.)
Literature Reference	Andersson, E., ''Energy consumption and air pollution of electric rail traffic, The Swedish case'', TRITA-FKT, Report 9446, Railway Technlogy, Department of Vehicle Engineering, Royal Institute of Technology, 1994.
Notes	The minimum and maximum value is caused by variations in external conditions (number of stops, topography, number of passings, the trains composition of trucks regarding aerodynamics, driving technique and climate)

About Inventory

Publication	www.ntm.a.se Data Documented by Magnus Blinge, Dept. for Transportation & Logistics, Chalmers University of Technology Data documented by: Ann-Christin Pålsson, CPM, Chalmers University of Technology
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compile a set of data for the different traffic modes that are accepted by representatives for all traffic modes (air, rail, road and sea). In order to be able to make correct assessments, it is crucial to have knowledge of the different functions used for calculations, assumptions and environmental load of different modes of transportation. The ambition within NTM (Network for goods transportation and the environment) is to compile and document relevant environmental interventions associated with different transport systems, and to localise gaps of knowledge. The network is also intended to serve as a forum for discussion between different actors in the transport business. The members of NTM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology and the Swedish Society for Natural Conservation
Detailed Purpose	The first step in the work of NTM was to gather available data for energy use and emissions for the operation of different goods transport systems. The work is conducted in working group 1 of NTM, which consists of representatives from the organisations that are members of NTM. All work is based on voluntary contributions from the representatives. Data was obtained for energy use and emissions to air, both from the traffic systems and the energy supply systems (i.e. oil refining and electricity generation)

	The ambition was to present a span constructed by a ''low'', an average and a ''high'' value since the energy use and emissions to air in real traffic situations may vary greatly. These differences were calculated as differences in fuel and electricity consumption for the technology in use today. Where available, measurement data for regular traffic would be reported. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.

Applicability	The data should not be used for detailed studies of transportation activities. More detailed data is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to obtain information in these matters. Railway traffic generally handles transportation of large heavy goods over long distances. Both electrically driven and diesel driven trains may be used. Electrically driven trains transport 95 % of the goods handled by train. Each truck of the trains may be assumed to have a loading capacity with regard to weight of 55 tonnes and a maximum gross weight of 80 tonnes. The trains are normally marshalled. Electrically driven combi train consists of trucks loaded with load carriers that also may be loaded and transported by truck. The share of goods transported by combi trains are about 5 % of the total amount of goods transported by electrically driven trains. Electyrically driven system trains are not recoupled on the way and always take the same route between two adresses. No marshalling is done, but a diesel engine may be used at the end points. The trains are generally fully loaded one way, and empty on the return trip, i.e. the utilisation level is about 50 % or higher. System trains ordinarily runs special transportation assignments for different types of industry. Diesel driven engines (T44) are mainly used for shunting and for regular traffic in sections where there is no aerial line. There are still some sections of the swedish railway system that are not electrified. SJ also uses smaller diesel engines (V5) for shunting. The V5 engine has a capacity of 400-500 tonnes gross weight and is not used for regular traffic. -- Marshalling -- The major part of the goods is marshalled at 6 main junctions where the goods are gathered and new trains are put together for new destinations. Shunting is generally done by diesel driven engines and is performed in two ways: -Hump shunting (valväxling) -Fly shunting (planväxling) -- Distance -- The railway network and the fact that the goods generally are marshalled means that the goods not always travel the shortest route between two destinations. When using the data, the distance may thus be difficult to assess. The company carrying out the transport should be contacted to get an accurate estimate of the distance. SJ has developed an environmentl data software with a databas of distances between 70 different places, concidering the infrastructure. The database does however not give information on which lines that arenot electrified. -- Bulky goods -- The data can be used for bulcy goods with the recalculation of the volume of the goods to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. -- Emissions from electricity production -- When using the data, the electricity production should be included, especially when comparing different modes of transportation. The emissions from electricity production can be calculated from the mix of electricity production processes that the electricity supplyers have that supplies SJ with electricity. SJ buys exclusivally ''ecolabelled'' electricity, i.e. hydro power with the following emission data (Brännström-Norberg et al., 1996): CO2: 0,0677 (g/kWh electr.) NOx: 0,000263 SO2: 0,000109 CO: 0,0018 Particl.: 0,0000295 HC: 0,000247 NTM has agreed on this way of calculating if the supplyer and buyer have a contract. Flow Data

General Activity QMetaData

Date Conceived	1997-01-01
Data Type	Derived, unspecified
Represents	NTM
Method	The electricity consumption was calculated using the assumption that the energy use may be reduced by 35 % by new engines and rebuilding existing engines together with data for existing trains in regular traffic with the lowest energy use. The assumption was based on Andersson. The electricity consumption per tonkm was calculated using an load factor of 46%. The data for trains in use in regular traffic today can be found in the activity ObjectOfStudy.Name: Electrically driven goods train 700 metres, RC engine (in this database)or in NGM. The minimum value for the energy use was used in the calculation. The data is based on measurements on freight trains in regular traffic conducted between 1994 and 1997 by the Department of Vehicle Engineering, Railway Technology, Royal Institute of Technology (KTH). The data includes losses in the railway supply system.
Literature Reference	Andersson, E., 'Future Energy Consumption of the Railways' (in Swedish), TRITA-FKT 1996:49, Railway Technology, Department of Vehicle Engineering, Royal Institute of Technology, 1994. NGM (Nätverket för Godstransporter och Miljön) Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997, NGM, (In Swedish) 1997
Notes	The minimum and maximum value in electricity consumption is caused by variations in external conditions (number of stops, topography, number of passings, the trains composition of trucks regarding aerodynamics, driving technique and climate)

Publication	*Energi- och emissionsuppgifter för godstransporter i Sverige. Ett konsensusdokument för övergripande jämförelser mellan transportslagen, Lägesbeskrivning november 1997,* NGM (Nätverket för Godstransporter och Miljön), (In Swedish) 1997 -- Data documented by: Ann-Christin Pålsson, CPM/TEP, Chalmers University of Technology Documentation reviewed by: Ingela Melkersson, SJ Stab Information, contact person for rail transports in the work of NGM --
Intended User	Suppliers and buyers of goods
General Purpose	There is an interest to compare different modes of transportation according to a joint basis. In order to be able to make correct assessments, it is crucial to have a thorough knowledge of the different function, assumptions and environmental load of different modes of transportation. The ambition within NGM (Network for goods transportation and the environment) is to compile and document all relevant environmental interventions associated with all modes of goods transportation, and to localise gaps of knowledge. The work is also intended to serve as a forum for discussion between different actors in the transportation business. The members of NGM consists of organisations representing road, rail, air and sea transport companies, interest groups, authority, university, research institutes etc. Example of organisations that participate in the work: BTL (Bilspedition Transportation and Logistics), ASG, SJ, FFA (The Aeronautical Research Institute of Sweden), Swedish Shipowners' Association, The Swedish Road Haulage Association, The Swedish Environmental Protection Agency, Vägverket, Sjöfartsverket, Department of Transportation and Logistics at Chalmers University of Technology, Naturskyddsföreningen
Detailed Purpose	The first step in the work of NGM was to gather available data for energy use and emissions for the operation of different modes of goods transportation. The work is conducted in working group 1 of NGM, which consists of representatives from the organisations that are members of NGM. All work is based on voluntary contributions from the representatives. The ambition was to present data for the ''best'', average and ''worst'' technology in use today. Where available, data for regular traffic would be reported, since the energy use and

	emissions in real transportation situations may vary greatly. The aim was also to get a picture of future energy use and emissions from transportation, through best available technology and future regulations, not yet in use.
Commissioner	- NGM (Nätverket för Godstransporter och Miljön), c/o TFK, Box 12667, S-112 93 Stockholm, Sweden.
Practitioner	Trouve, Johan - SJ (Swedish State Railways), Stab Information, Box 1522, 401 50 Göteborg.
Reviewer	
Applicability	The ambition with the data was to get a picture of future energy use and emissions for Swedish train traffic. The data represents new technology not yet in use.
About Data	***Electricity consumption*** The electricity consumption was based on assumptions that the energy use in the existing system may be reduced by 35% by different energy saving measures, rebuilding existing engines and new engines. ***Emissions from electricity production*** When using the data, the electricity production should be included, especially when comparing different modes of transportation. SJ and NGM propose that the following data for average Swedish electricity production should be used to calculate the emissions from electricity production: -NOx: 0,038 g/kWh produced electricity -S: 0,021 g/kWh produced electricity -CO: 0,023 g/kWh produced electricity -HC: 0,0003 g/kWh produced electricity -CO2: 20,8 g/kWh produced electricity The data was given by Vattenfall AB and concern the Swedish electricity production in 1993. The following production methods were used: Hydro-electric power (52%), Nuclear power (42%), Wind power (0,04%), Thermal power (6%) where 2% is fuelled by fossil fuels. Today, SJ buys electricity from Vattenfall and Tälje energi
Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

SPINE LCI dataset: Electrically driven system train, RC engine

Administrative	
Finished	Y
Date Completed	1997-11-19
Copyright	NGM (Nätverket för Godstransporter och Miljön)
Availability	This version is only available to the members of NTM. The data is continously updated, and the data user should always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se.

Technical System	
Name	Electrically driven system train, RC engine
Functional Unit	1 tonkm, 46 %

Functional Unit Explanation	Energy use and emissions refer to the transportation of 1 ton goods 1 kilometre for an utilisation level of 46 %. An utilisation level of 46 % is representative for Swedish domestic traffic if *transportation of empty trucks are included.*
Process Type	Unit operation
Site	Sweden
Sector	Land transport
Owner	Sweden
Technical system description	Operation of an electrically driven system train, driven by an RC engine. Electrically driven system trains are not recoupled on the way and always take the same route between two addresses. No marshalling is done, but a diesel engine may be used at the end points. System trains ordinarily runs special transportation assignments for different types of industry The operation includes -Propulsion (including auxiliary machinery and safety systems) -Comfort during the journey -Complimentary runs -Stationary vehicle heating -Operation of fixed installations (not including heating of premises) Maximum gross weight of the train: 1500 tonnes. Maximum loading capacity with regard to weight: 1031 tonnes.

System Boundaries

Nature Boundary	Diffuse emissions to air and emissions to water and ground, noise, encroachment and other environmental impacts have not been considered.
Time Boundary	The data represents the fleet in 1997
Geographical Boundary	The data is based on Swedish conditions.
Other Boundaries	The average utilisation level is 46 %. The utilisation level includes transportation of empty trucks. *Parameters not considered* -Driving technique -Maintenance level of the engine -External conditions i.e. climate etc. -Use of lubricating oil -Wear of brake lining, rail and wheel, aerial line and collector shoe *Excluded subsystems* -Electricity production -Maintenance of the engine -After-treatment of the engine -Handling of production rests -Manufacturing of vehicles and other equipment -Heating of buildings serving the transportation system -Erection and maintenance of infrastructure
Allocations	N/A
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1994-01-01 - 1997-01-01
Data Type	Random samples
Represents	NTM
Method	The electricity consumption is based on measurements on 6000 freight trains in regular traffic conducted between 1994 and 1997 by the Department of Vehicle Engineering, Railway Technology, Royal Institute of Technology (KTH). The electricity consumption per tonkm was calculated using an load factor of 46%. The *quantity value* refers to an average of the energy use of the studied trains. The *minimum and maximum value* refers to the minimum and the maximum value obtained by the measurements. Current and voltage were measured in the trains tractive units (locomotive or motor coach), at the energy input close to the current collector. Additions were then made for losses in the railways supply system. The results thus obtained give electrical energy consumption per gross-tonne-km reckoned in power outtake from the national grid. The energy use was calculated per net-tonne-km as a function of the trains capacity and load factor. The losses in the railway supply system include losses in converters and catenary cables (efficiency 81,8% for supply

	to RC locomotives) and losses suffered in transmitting electricity from the power station to the feed-in point (the losses are assumed to be approx. 4 %) For further details see Andersson. The load factor that was used in the calculations is a representative mean value for different types of freight traffic, based on statistics from the State Railways Freight Transportation Division and State Railways Financial department. For the whole of State Railways Freight traffic, excluding iron-ore transport, the mean load factor was about 46% in 1993. (Load factor=net-tonne/gross-tonne where the gross-tonne concept refer to train weight, including locomotive freight wagons and load. The net-tonne concept refers to payload after the weight of the locomotive and wagons have been excluded.)
Literature Reference	Andersson, E., ''Energy consumption and air pollution of electric rail traffic, The Swedish case'', TRITA-FKT, Report 9446, Railway Technlogy, Department of Vehicle Engineering, Royal Institute of Technology, 1994.
Notes	The minimum and maximum value is caused by variations in external conditions (number of stops, topography, number of passings, the trains composition of trucks regarding aerodynamics, driving technique and climate)

Applicability	The data should not be used for detailed study of transportation. More detailed information is then needed e.g. regarding the vehicle performance, the nature of the goods, the utilisation level etc. For specific transports, the company carrying out the transport should be contacted to obtain information on how the goods are handled and the transport is carried out. Railway traffic generally handles transportation of large heavy goods over long distances. Both electrically driven and diesel driven trains may be used:

	Electrically driven freight trains transport 95 % of the goods handled by train. Each truck of the trains may be assumed to have a loading capacity with regard to weight of 55 tonnes and a maximum gross weight of 80 tonnes. The trains are normally marshalled. *Electrically driven combi train* consists of trucks loaded with load carriers that also may be loaded and transported by truck. The share of goods transportation by combi train is about 5 % of the total transportation by electrically driven goods trains. *Electrically driven system trains* are not recoupled on the way and always take the same route between two addresses. No marshalling is done, but a diesel engine may be used at the end points. The trains are generally fully loaded one way, and empty on the return trip, i.e. the utilisation level is 50% or higher. System trains ordinarily runs special transportation assignments for different types of industry. *Diesel driven engines* (T44) are mainly used for shunting and for regular traffic in sections where there is no aerial line. There are still some sections of the Swedish railway system that are not electrified. SJ also uses a smaller diesel driven engine (V5) for shunting. The V5 engine has a capacity of 450-500 tonnes gross weight and is not ordinarily used for regular traffic. ***Marshalling*** The major part of the goods is marshalled at 6 main junctions were the goods are gathered and new trains are put together for new destinations. Shunting is generally done by diesel driven engines and is performed in two ways: -Hump shunting (vallväxling) -Fly shunting (planväxling) ***Distance*** The railway network and the fact that the goods generally are marshalled means that the goods not always travel the shortest route between two destinations. When using the data, the distance may thus be difficult to assess. The company carrying out the transport should be contacted to get an accurate estimate of the distance. SJ (Swedish State Railways) has developed environmental data software with a database of distances between 70 different places, considering the infrastructure. The database does however not give information on which lines that are not electrified. ***Bulky goods*** The data may be used for bulky goods by recalculation of the volume of the goods to an equivalent weight by the following conversion factor: 250 kg/m3. The conversion factor is generally accepted in the transportation business. ***International train traffic*** The data for the energy use may be used for train transports in Europe, since the technique in other countries are similar (electrically and diesel driven engines). The handling of the goods may however differ in different countries, e.g. regarding average utilisation level etc. Also, the electricity production in different countries varies.
About Data	***Electricity consumption*** The electricity consumption was obtained by energy studies of 6000 trains in regular traffic, including losses in the railway supply system. Several parameters thus influence the energy use, such as e.g. topography, driving technique, the number of starts and stops, number of passing, the trains composition of trucks regarding aerodynamics and the weight of the train etc. The electricity consumption is roughly proportional to the weight of the train. Consequently, the electricity consumption per tonkm for a given utilisation level is approximately constant, independent on the size of the train. ***Utilisation level*** For electrically driven goods trains, the data is based on an average utilisation level of 46 % (including transportation of empty trucks). The average utilisation level was based on statistics from 1993 from the Swedish State Railways. Today the average utilisation level is higher according to the Swedish State Railways due to different actions to use the trains more effectively. The utilisation level for a specific transport may vary. There are however no general rules regarding differences in the utilisation level, and what utilisation level to chose for a specific transport operation. ***Emissions from electricity production*** When using the data, the electricity production should be included, especially when comparing different modes of transportation. SJ and NGM propose that the following data for average Swedish electricity production should be used to calculate the emissions from electricity production: -NOx: 0,038 g/kWh produced electricity -S: 0,021 g/kWh produced electricity -CO: 0,023 g/kWh produced electricity -HC: 0,0003 g/kWh produced electricity -CO2: 20,8 g/kWh produced electricity The data was given by Vattenfall AB and concern the Swedish electricity production in 1993. The following production methods were used: Hydro-electric power (52%), Nuclear power (42%), Wind power (0,04%), Thermal power (6%) where 2% is fuelled by fossil fuels. Today, SJ buys electricity from Vattenfall and Tälje energi.

Notes	The data is continously updated, and the data user should therefore always make sure to use the most recent version of the data, which is published on the NTM homepage: http://www.ntm.a.se. The work within NGM will continue to further increase the knowledge of different environmental interventions associated with goods transportation. The representatives for road transports (e.g. Volvo, Scania, Bilindustriföreningen, BTL Åkeriförbundet etc.) are currently compiling new data on energy use and emissions from road transports which is expected to be available in the end of February 1997. SJ and Vattenfall AB are working on new data on the environmental load of electricity production which also will be available at the end of February 1998. The major Swedish actors in the transportation business, which are members of NGM (e.g. SJ, BTL, ASG etc.), will use the data as a basis for environmental assessment of different transportation alternatives. The secretary for the work is Sebastian Bäckström, Department of Transportation and Logistics at Chalmers University of Technology.

Technical system description	This is a compliation of regionalized LCI datasets for electricity production and distribution in India. The technical boundary starts at the constructed power plant ready to produce electricity (excluded: fuel extraction, processing, and transportation to the power plant) and ends at the power distribution grid where electricity is available for consumption. The activities contain domestic production, import from neighbouring grids (including Bhutan), transmission and transformation infrastructure, associated emissions, and losses during transmission according to ecoinvent methodology. Electricity production datasets per Indian states/unions and territories: Lignite Hard coal Oil Natural gas Nuclear Wind Solar Import of electricity from Bhutan. Production mix and transformation and distribution per Indian regional grids. For detailed information please see Hossain M N, 2016, "Regionalized Life Cycle Inventory of

	Power Producing Technologies and Power Grids in India", master thesis report, Industrial Ecology programme, Chalmers University of Technology, Dept. Energy and Envrionment, Div. of Environmental Systems Analysis, ESA report 2016:15 The LCI data are available in Excel spreadsheets here: Hossain_2016_Electricity_production_and_distribution_India_regionalized.zip User Guide to the excel files The datasets on electrcity production from different sources across Indian States/Union Territory, and Transformartion and Transmission of electricity via regional grids. The excel files show the the specific parameter data we have collected and specific equations we have used to calculate emissions from electricity producing technologies in India. Each file contains a readme tab which describes the name and content of the other tabs. Specifically, " production_mix_India_MNH documents electricity mix of Indian Geographic Units (i.e. States, Union Territories, Regions). " import_India_MNH documents the import from Bhutan. " electricity transformation and transmission losses_India_MNH documents all the electricity losses due to the transformation and transmission among the regional grids. " Other files document dataset on electricity production from different sources (i.e. hard coal, lignite, natural gas, oil, hydro, nuclear, wind, and solar). The datasets are now undergoing the documentation phase to be submitted to the reference LCI database - ecoinvent which will be available in ecospold format.

System Boundaries

Nature Boundary	
Time Boundary	The inventory is prepared as for 2012 because latest and most consistent data was available for the fiscal year 2012-13.
Geographical Boundary	Electricity distribution per 5 regional grids in India. Import of electricity from Buthan. Electricity production from 25 (of 28) states and 4 (of 7) union territories. 3 states (Chandigarh, Daman and Diu, and Dadar & Nagar Haveli) and 3 union territories (Lakshadweep, Andaman and Nicobar, and Mizoram) out not included due to no or negligleble production capacity and also very small consumption.

Availability	Public

Technical System	
Name	Electronic Control Unit’s aluminium capacitor manufacturing. Autoliv ESA-DBP
Functional Unit	1.6 gram of aluminium capacitor
Functional Unit Explanation	Aluminium capacitor is a part of an electronic control unit which weighs 427.07 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	A capacitor is an electronic component that stores energy in the form of an electric field. It can also be used as a filter of signals with different frequencies. It is made of conductors separated with an insulator or dialectric. There are many types of capacitors for example: electrolytic (aluminium or tantalum), ceramic and many others In an electronic control unit 4 different types of capacitors are placed; aluminium, cradle, tantalum and ceramic. In the studied aluminium capacitor there are 2 aluminium electrodes

	and paper as an isolator. The rest of the materials has a housing function and to connect into the circuit. This process is included in the system described in: Gu S., Liu J. (2010). Life cycle assessment of Autoliv's Electronic Control Unit. Master thesis report. ESA report 2010:5, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2010--9.pdf Other processes in the CPM Database also included in the above publication: - Electronic Control Unit's label manufacturing. Intended User	LCA practitioner
General Purpose	Autoliv has decided to perform 4 LCA projects for the following products: airbag, seatbelt, night vision camera (NVC) and electronic control unit (ECU). The main purpose was to learn more about the products and their environmental performances and eventually decrease their impact on the environment.
Detailed Purpose	The discussed aluminium capacitor is a part of the electronic control unit which was the object of the study. The main goals of the study are (excerpt from the report, see 'Publication'): ''1.What kind of environmental impacts can be associated with ECU production? In which process life cycle of ECU production has the biggest responsibility for adverse environmental impacts? 2. Analyses on different environmental impacts as potential, calculate the consumption of different energy resources, and quantities of waste in all life cycle. 3. Decide which materials in the ECU could be avoided for better environmental impacts.''
Commissioner	Autoliv Development AB - .

Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above.
About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	The general function of an electronic control unit is controlling the internal systems in a vehicle. It controls and manages safety equipment. It gathers and processes signals from the sensors located in the car in order to cause an action if needed. It was assumed in the report that an electronic control unit is dismantled from a car before the latter is squashed into the cube and shredded. The electronic control unit is then disassembled into some segments. Plastic parts are recovered as energy whereas the metal parts are recycled. The most crucial part - PCB (printed circuit board) as a separate part is sent to the special oven and as a result of this process metals are recycled in a rate of 96-99% when the plastics are recovered as energy. The studied product is a part of the electronic control unit which was the object of the LCA study for Autoliv. More processes from the same study were also documented in this database. In parallel to the electronic control unit, 3 other LCA studies for Autoliv were carried out (for airbag, seatbelt and night vision camera). Some of the processes can be found also in the CPM database.

Intended User	LCA practitioner
General Purpose	Autoliv has decided to perform 4 LCA projects for the following products: airbag, seatbelt, night vision camera (NVC) and electronic control unit (ECU). The main purpose was to learn more about the products and their environmental performances and eventually decrease their impact on the environment.
Detailed Purpose	The discussed connector is a part of the electronic control unit which was the object of the study. The main goals of the study are (excerpt from the report, see 'Publication'): ''1.What kind of environmental impacts can be associated with ECU production? In which process life cycle of ECU production has the biggest responsibility for adverse environmental impacts? 2. Analyses on different environmental impacts as potential, calculate the consumption of different energy resources, and quantities of waste in all life cycle. 3. Decide which materials in the ECU could be avoided for better environmental impacts.''

Technical System	
Name	Electronic Control Unit's inductor choke manufacturing. Autoliv ESA-DBP
Functional Unit	3.66 grams of inductor choke
Functional Unit Explanation	1 inductor choke is a part of an electronic control unit which weighs 427.07 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	An inductor choke in electrical devices blocks higher frequencies in an electrical circuit and passes signals of lower frequency or direct current. In the electronic control unit it is one of the inductors together with coil, common mode filter and TBD. The role of the inductor is to distinguish the signals sent from the sensors into these wanted and unwanted ones. The choke consists of Zn-Ni ferrite core and a wire which is made of copper. The manufacturing process starts with mounting the core which is followed by winding the wire and fastening it to the core by ultrasonic welding. In the end it is tested and packed before dispatch. It is manufactured in the company which is located in China and then transported to Autoliv Motala in Sweden. This process is included in the system described in: Gu S., Liu J. (2010). Life cycle assessment of Autoliv's Electronic Control Unit. Master thesis report. ESA report 2010:5, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Technical System	
Name	Electronic Control Unit's integrated circuit ASIC manufacturing. Autoliv ESA-DBP

Functional Unit	0.11 grams of integrated circuit ASIC
Functional Unit Explanation	Integrated circuit ASIC (application specific integrated circuit) is a part of an electronic control unit which weighs 427.07 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	An integrated circuit is a small chip that consists of a small waffer with semiconductor devices such as transistors, resistors and capacitors. It is manufactured in a surface of a thin semiconductor material. The studied product consists of silicon (chip), silver (die attach and die plating), alloy nickel iron (leadframe), gold (wire), silica (encapsulation) and tin. It is produced in Malaysia and transported to Motala, Sweden. The manufacturing process of integrated circuit is presented in the reference report: (excerpt from the report, see 'Publication') ''Regarding the process of manufacturing, wafer mounting and sawing are performed as the first step in the process. Afterwards, Die attach is bounded to the lead frame. Later on, the processes of snap cure, wire bonding, molding, post mode cure, deflashing, plating and cropping are performed in turn. Lastly, manufacturing of integrated circuit is ended up with labeling and packing''. This process is included in the system described in: Gu S., Liu J. (2010). Life cycle assessment of Autoliv's Electronic Control Unit. Master thesis report. ESA report 2010:5, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. It was assumed in the report that an electronic control unit is dismantled from a car before the latter is squashed into the cube and shredded. The electronic control unit is then disassembled into some segments. Plastic parts are recovered as energy whereas the metal parts are recycled. The most crucial part - PCB (printed circuit board) as a separate part is sent to the special oven and as a result of this process metals are recycled in a rate of 96-99% when the plastics are recovered as energy. The studied product is a part of the electronic control unit which was the object of the LCA study for Autoliv. More processes from the same study were also documented in this database. In parallel to the electronic control unit, 3 other LCA studies for Autoliv were carried out (for airbag, seatbelt and night vision camera). Some of the processes can be found also in the CPM database.

Technical System	
Name	Electronic Control Unit’s integrated circuit comparator manufacturing. Autoliv ESA-DBP
Functional Unit	0.0147 grams of integrated circuit comparator
Functional Unit Explanation	Integrated circuit comparator is a part of an electronic control unit which weighs 427.07 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	An integrated circuit is a small chip that consists of a small waffer with semiconductor devices such as transistors, resistors and capacitors. It is manufactured in a surface of a thin semiconductor material. An integrated circuit comparator is used to compare 2 different voltages or currents and indicates the result as output (Wikipedia 1b, 2010). The studied product consists of silicon (chip), silver (attach and internal lead finish), tin (solder), mold compound (silica), copper (leadframe) and gold (wire). It is produced in Melaka, Malaysia and transported to Motala, Sweden. The manufacturing process of integrated circuit is presented in the reference report: (excerpt from the report, see ’Publication’) ’’Regarding the process of manufacturing, wafer mounting and sawing are performed as the first step in the process. Afterwards, Die attach is bounded to the lead frame. Later on, the processes of snap cure, wire bonding, molding, post mode cure, deflashing, plating and cropping are performed in turn. Lastly, manufacturing of integrated circuit is ended up with labeling and packing’’. This process is included in the system described in: Gu S., Liu J. (2010). Life cycle assessment of Autoliv’s Electronic Control Unit. Master thesis report. ESA report 2010:5, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Intended User	LCA practitioner
General Purpose	Autoliv has decided to perform 4 LCA projects for the following products: airbag, seatbelt, night vision camera (NVC) and electronic control unit (ECU). The main purpose was to learn more about the products and their environmental performances and eventually decrease their impact on the environment.
Detailed Purpose	The discussed integrated circuit comparator is a part of the electronic control unit which was the object of the study. The main goals of the study are (excerpt from the report, see 'Publication'): ''1.What kind of environmental impacts can be associated with ECU production? In which

	process life cycle of ECU production has the biggest responsibility for adverse environmental impacts? 2. Analyses on different environmental impacts as potential, calculate the consumption of different energy resources, and quantities of waste in all life cycle. 3. Decide which materials in the ECU could be avoided for better environmental impacts.''

About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for

	environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	The general function of an electronic control unit is controlling the internal systems in a vehicle. It controls and manages safety equipment. It gathers and processes signals from the sensors located in the car in order to cause an action if needed. It was assumed in the report that an electronic control unit is dismantled from a car before the latter is squashed into the cube and shredded. The electronic control unit is then disassembled into some segments. Plastic parts are recovered as energy whereas the metal parts are recycled. The most crucial part - PCB (printed circuit board) as a separate part is sent to the special oven and as a result of this process metals are recycled in a rate of 96-99% when the plastics are recovered as energy. The studied product is a part of the electronic control unit which was the object of the LCA study for Autoliv. More processes from the same study were also documented in this database. In parallel to the electronic control unit, 3 other LCA studies for Autoliv were carried out (for airbag, seatbelt and night vision camera). Some of the processes can be found also in the CPM database.

Technical System	
Name	Electronic Control Unit’s MEMS based sensor manufacturing. Autoliv ESA-DBP
Functional Unit	0.759 gram of sensor
Functional Unit Explanation	The sensor is a part of an electronic control unit which weighs 427.07 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	Excerpt from the report, see 'Publication': ''MEMS-Based Sensor is manufactured by our sensor supplier in Japan, which is used to sense and control the surrounding environment. (...) The sensor mounted on PCB board, mainly consists of silicon die, mold compound, copper leadframe and tin plating. (...) Manufacturing of sensor is starting from etching cavities in glass and electrodes. Next, bonding between SOI wafer and glass is conducted, and then back silicon wafer is etched. Afterward, lithographically pattern is performed to release silicon microstructures. Finally, manufacturing process of sensor is ended up with testing and sent to customers later on.'' This process is included in the system described in: Gu S., Liu J. (2010). Life cycle assessment of Autoliv's Electronic Control Unit. Master thesis report. ESA report 2010:5, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2010--9.pdf Other processes in the CPM Database also included in the above publication: - Electronic Control Unit's label manufacturing. Autoliv ESA-DBP - Electronic Control Unit's housing manufacturing. Autoliv ESA-DBP - Electronic Control Unit's screw manufacturing. Autoliv ESA-DBP - Electronic Control Unit's inductor manufacturing. Intended User	LCA practitioner
General Purpose	Autoliv has decided to perform 4 LCA projects for the following products: airbag, seatbelt, night vision camera (NVC) and electronic control unit (ECU). The main purpose was to learn more about the products and their environmental performances and eventually decrease their impact on the environment.
Detailed Purpose	The discussed sensor is a part of the electronic control unit which was the object of the study. The main goals of the study are (excerpt from the report, see 'Publication'): ''1.What kind of environmental impacts can be associated with ECU production? In which process life cycle of ECU production has the biggest responsibility for adverse environmental impacts? 2. Analyses on different environmental impacts as potential, calculate the consumption of different energy resources, and quantities of waste in all life cycle. 3. Decide which materials in the ECU could be avoided for better environmental impacts.''

Technical System	
Name	Electronic Control Unit’s Printed Circuit Board (PCB) base manufacturing. Autoliv ESA-DBP
Functional Unit	46.6 grams of a PCB board
Functional Unit Explanation	PCB board is a part of electronic control unit which weighs 427.07 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	Excerpt from the report, see ’Publication’: ’’PCB board is playing an indispensable part in entire PCB, which is acted as a carrier to mount every electronic component on the board. Besides, PCB board is also performed as a bridge, it makes electronic signal transforms via the board’s conductive paths.’’ The studied PCB base is made of copper, glass fibre, epoxy resin and silver. It weighs 46.6 grams and it is manufactured in the plant located in the east of China and then transported to Autoliv Motala, Sweden. This process is included in the system described in: Gu S., Liu J. (2010). Life cycle assessment of Autoliv’s Electronic Control Unit. Master thesis report. ESA report 2010:5, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Technical System	
Name	Electronic Control Unit's resistor manufacturing. Autoliv ESA-DBP
Functional Unit	0.00068 gram of resistor
Functional Unit Explanation	Resistor is a part of electronic control unit of which the total weight is 427.07 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	Excerpt from the report, see 'Publication': ''The resistor is one of the most common used electronic components in PCB, it is mainly used to restrict and reduce the flow of electric current in an electronic circuit. There are many pieces of resistor used in this studied ECU, which part of them are manufactured at one supplier in Malaysia. And other items are produced at one supplier, in Taiwan. Additionally, all of these resistors are the type of thick film resistor and mainly contain raw materials of solder, nickel, aluminium oxide part and electrode (silver). (...) Even though these resistors are produced in different plants, the manufacturing processes are almost same for this product. Firstly, incoming materials are inspected by the plants followed by printing the front and back terminals. Meanwhile, resistive elements and glass coat are printed as well as terminals. Following printing, aging of resistors is conducted before QC

	test. Finally, the manufacturing processes are finished, and all products get ready to be delivered. Speaking of transportation, since both these two manufacturing plants are located in Asia, therefore, products are supposed to pass by one of the European harbors, after that are delivered to Autoliv Motala.'' The resistors are placed in a printed circuit board. This process is included in the system described in: Gu S., Liu J. (2010). Life cycle assessment of Autoliv's Electronic Control Unit. Master thesis report. ESA report 2010:5, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Intended User	LCA practitioner
General Purpose	Autoliv has decided to perform 4 LCA projects for the following products: airbag, seatbelt, night vision camera (NVC) and electronic control unit (ECU). The main purpose was to learn more about the products and their environmental performances and eventually decrease their impact on the environment.
Detailed Purpose	The discussed resistor is a part of the electronic control unit which was the object of the study. The main goals of the study are (excerpt from the report, see 'Publication'): ''1.What kind of environmental impacts can be associated with ECU production? In which process life cycle of ECU production has the biggest responsibility for adverse environmental impacts? 2. Analyses on different environmental impacts as potential, calculate the consumption of different energy resources, and quantities of waste in all life cycle. 3. Decide which materials in the ECU could be avoided for better environmental impacts.''

Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	The general function of an electronic control unit is controlling the internal systems in a vehicle. It controls and manages safety equipment. It gathers and processes signals from the sensors located in the car in order to cause an action if needed. It was assumed in the report that an electronic control unit is dismantled from a car before the latter is squashed into the cube and shredded. The electronic control unit is then disassembled into some segments. Plastic parts are recovered as energy whereas the metal parts are recycled. The most crucial part - PCB (printed circuit board) as a separate part is sent to the special oven and as a result of this process metals are recycled in a rate of 96-99% when the plastics are recovered as energy. The studied product is a part of the electronic control unit which was the object of the LCA study for Autoliv. More processes from the same study were also documented in this database. In parallel to the electronic control unit, 3 other LCA studies for Autoliv were carried out (for airbag, seatbelt and night vision camera). Some of the processes can be found also in the CPM database.

Technical System	
Name	Electronic Control Unit's resonator manufacturing. Autoliv ESA-DBP
Functional Unit	0.011 gram of resonator
Functional Unit Explanation	Resonator is a part of an electronic control unit which weighs 427.07 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	Excerpt from the report, see 'Publication': ''Resonator is an electronic component that could indicate resonance of narrow range frequencies, which is used for concentrating electric fields in ECU. (...) The resonator company starts produce resonator by calcinating the mixed raw materials to form the ceramic body. Subsequently, the processes of sintering, lapping, polarizing, aging and cutting are performed in turn. Later on, before the outgoing inspection, all prepared resonators are conducted to be sorted, marked and tapped.'' The resonator is made of silver electrode, ceramic, aluminium oxide and plating layers.It is a one of the parts of Printed Circuit Board and it is produced in Japan and then transported to Autoliv Motala. This process is included in the system described in: Gu S., Liu J. (2010). Life cycle assessment of Autoliv's Electronic Control Unit. Master thesis report. ESA report 2010:5, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2010--9.pdf Other processes in the CPM Database also included in the above publication: - Electronic Control Unit's label manufacturing. Autoliv ESA-DBP - Electronic Control Unit's housing manufacturing. Autoliv ESA-DBP - Electronic Control Unit's screw manufacturing. Autoliv ESA-DBP - Electronic Control Unit's inductor manufacturing. Autoliv ESA-DBP - Electronic Control Unit's integrated circuit ASIC manufacturing. Autoliv ESA-DBP - Electronic Control Unit's integrated circuit MCU/memory manufacturing. Autoliv ESA-DBP - Electronic Control Unit's integrated circuit interface manufacturing. Autoliv ESA-DBP - Electronic Control Unit's integrated circuit comparator manufacturing. Autoliv ESA-DBP

System Boundaries	
Nature Boundary	The performed study is gate-to-gate. It starts with calcinating raw materials and ends with inspection and marking. Data given by resonator manufacturer show only waste water production. There is no information about the emissions.
Time Boundary	The data were acquired in 2010 as the most up-to-date ones.
Geographical Boundary	The manufacturing plant is located in Japan.
Other Boundaries	Excerpt from the report, see 'Publication': ''Maintenance of production capital as well as personnel related environmental impacts were excluded from the study. Transportation within the production plant was not included.''
Allocations	NB: In the reference report there is no information about the allocation process.
Systems Expansions	Not applicable

Technical System	
Name	Electronic Control Unit's screw manufacturing. Autoliv ESA-DBP
Functional Unit	1 screw
Functional Unit Explanation	1 screw weighs 0.71 grams and 7 screws are needed in 1 unit of electronic control unit.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	A screw is usually used for fastening the parts. There might be different sizes, materials and other parameters. The studied screw is 30x8 and it is made of steel, e-plate zinc and passivation layer of Zn/ZnFe/ZnNi. There are 7 screws in electronic control unit and they are manufactured in Bad Berleburg in Germany and then transported to Örebro, Sweden. Each of them weighs 0.71 gram. The manufacturing process consists of the following steps: 1. Creating the headed rivet 2. Degreasing 3. Forming the thread 4. Degreasing

	5. Heat treatment 6. Plating 7. Inspection 8. Packaging This process is included in the system described in: Gu S., Liu J. (2010). Life cycle assessment of Autoliv's Electronic Control Unit. Master thesis report. ESA report 2010:5, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Publication	Gu S., Liu J. (2010). Life cycle assessment of Autoliv's Electronic Control Unit. Master thesis report. ESA report 2010:5, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2010--9.pdf
Intended User	LCA practitioner
General Purpose	Autoliv has decided to perform 4 LCA projects for the following products: airbag, seatbelt, night vision camera (NVC) and electronic control unit (ECU). The main purpose was to learn more about the products and their environmental performances and eventually decrease their impact on the environment.
Detailed Purpose	The discussed signal diode is a part of the electronic control unit which was the object of the study. The main goals of the study are (excerpt from the report, see 'Publication'): ''1.What kind of environmental impacts can be associated with ECU production? In which process life cycle of ECU production has the biggest responsibility for adverse environmental impacts? 2. Analyses on different environmental impacts as potential, calculate the consumption of different energy resources, and quantities of waste in all life cycle. 3. Decide which materials in the ECU could be avoided for better environmental impacts.''
Commissioner	Autoliv Development AB - .

Reviewer	Birgit Brunklaus & Henrikke Baumann -
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	The general function of an electronic control unit is controlling the internal systems in a vehicle. It controls and manages safety equipment. It gathers and processes signals from the sensors located in the car in order to cause an action if needed. It was assumed in the report that an electronic control unit is dismantled from a car before the latter is squashed into the cube and shredded. The electronic control unit is then disassembled into some segments. Plastic parts are recovered as energy whereas the metal parts are recycled. The most crucial part - PCB (printed circuit board) as a separate part is sent to the special oven and as a result of this process metals are recycled in a rate of 96-99% when the plastics are recovered as energy. The studied product is a part of the electronic control unit which was the object of the LCA study for Autoliv. More processes from the same study were also documented in this database. In parallel to the electronic control unit, 3 other LCA studies for Autoliv were carried out (for airbag, seatbelt and night vision camera). Some of the processes can be found also in the CPM database.

SPINE LCI dataset: Electronic Control Unit's transistor manufacturing. Autoliv ESA-DBP

Technical System	
Name	Electronic Control Unit's transistor manufacturing. Autoliv ESA-DBP
Functional Unit	0.121 gram of transistor
Functional Unit Explanation	There are 4 of the transistors in the electronic control unit.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	A transistor is used for amplifying or switching the electronic signals. In the studied transistor, the semicondutor is made of silicon. Except for this material there are also silver (attaching and plating), copper (frame), gold (wire), silica (encapsulation) and tin (frame). The manufacturing process is presented below (excerpt from the report, see 'Publication'): ''In perspective of manufacturing process, production of transistor starts with bonding of silicon crystal die on the lead frame. Then, wire bounding and encapsulation (with epoxy plastic) are conducted by the manufacturing plant. Afterward, all components are soldered and tinplated. The last step is to trim unwanted edges, and then packing is performed for transporting to customers.'' This process is included in the system described in: Gu S., Liu J. (2010). Life cycle assessment of Autoliv's Electronic Control Unit. Master thesis report. ESA report 2010:5, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2010--9.pdf Other processes in the CPM Database also included in the above publication: - Electronic Control Unit's label manufacturing. Autoliv ESA-DBP - Electronic Control Unit's housing manufacturing. Autoliv ESA-DBP - Electronic Control Unit's screw manufacturing. Autoliv ESA-DBP - Electronic Control Unit's inductor manufacturing. Autoliv ESA-DBP - Electronic Control Unit's resonator manufacturing. Autoliv ESA-DBP - Electronic Control Unit's Printed Circuit Board (PCB) base manufacturing. Autoliv ESA-DBP - Electronic Control Unit's TVS diode manufacturing. Autoliv ESA-DBP - Electronic Control Unit's electronic connector manufacturing. Autoliv ESA-DBP - Electronic Control Unit's integrated circuit ASIC manufacturing. Autoliv ESA-DBP - Electronic Control Unit's integrated circuit MCU/memory manufacturing. Autoliv ESA-DBP - Electronic Control Unit's integrated circuit interface manufacturing. Autoliv ESA-DBP - Electronic Control Unit's integrated circuit comparator manufacturing. Autoliv ESA-DBP

System Boundaries	
Nature Boundary	The performed study is gate-to-gate. It starts with bonding of silicon crystal die on the lead frame and ends with trimming the outstanding edges. There is no information about the emissions.
Time Boundary	The data were acquired in 2010 as the most up-to-date ones.
Geographical Boundary	The manufacturer is located in Kulim, Malaysia.

Other Boundaries	Excerpt from the report, see 'Publication': ''Maintenance of production capital as well as personnel related environmental impacts were excluded from the study. Transportation within the production plant was not included.''
Allocations	NB: In the reference report there is no information about the allocation process.
Systems Expansions	Not applicable

Technical System	
Name	Electronic Control Unit’s TVS diode manufacturing. Autoliv ESA-DBP
Functional Unit	0.11 gram of TVS diode
Functional Unit Explanation	TVS diode is a part of an electronic control unit which weighs 427.07 grams.
Process Type	Gate to gate
Site	Unknown
Sector	Manufacturing
Owner	Unknown
Technical system description	A diode is a two-terminal electronic component that conducts electric current in only one direction. A TVS (Transient Voltage Suppression) diode is used to suppress overvoltage when the induced voltage exceeds the avalanche breakdown potential. The studied diode consists of die TVS set, gold (wire), alloy, silver (solder), EP glass, tin (plate) and copper (plate). The ready product is mounted on a printed circuit board. The general description of production process was contained in the report (excerpt from the report, see ’Literature reference’): ’’Manufacturing of diode begins with wafer sawing. Secondly, silicon die bonding and soldering are conducted. Thirdly, moulding and de-flashing are followed by. Afterward, the initial diodes are formed. Next, products are sent to test and mark. Finally, diodes are packed for delivering.’’ This process is included in the system described in: Gu S., Liu J. (2010). Life cycle assessment of Autoliv’s Electronic Control Unit. Master thesis report. ESA report 2010:5, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. SPINE LCI dataset: Ethanol from sugar beets, cradle-to-gate, energy allocation - f3 fuels

Administrative	
Finished	Y
Date Completed	2013-11-30
Copyright	f3 - Swedish Knowledge Centre for Renewable Transportation Fuels
Availability	Public

Technical System	
Name	Ethanol from sugar beets, cradle-to-gate, energy allocation - f3 fuels
Functional Unit	1 MJ
Functional Unit Explanation	1 MJ output of ethanol from sugar beets
Process Type	Cradle to gate
Site	
Sector	Fuel
Owner	

Technical system description	This dataset represents a model of the production of ethanol from sugar beets valid for southern Sweden. The following process are covered: - Cultivation of the sugar beets - Harvest - Distribution to the fuel plant - Production of ethanol The mineral fertilizer used is assumed partly to be produced in Western Europe (about 60 %) with present level of cleaning equiptment etc., and partly imported from countries outside Europe (about 40 %). This implies that about 30 % of the mineral fertilizer production takes place in plants with nitrous oxide cleaning where the nitrous oxide emission levels are reduced with about 80 %. All electricity input in the ethanol-plant is Swedish grid mix. Fuel used at the ethanol plant for is of forest origin. Allocation is made based on energy content (only case published in "Miljöfaktaboken" (see references), since this allocation method is preferred by the Renewable Energy Directive), however a case with system expansion is made in Börjesson et al. which also has been published in the f3 database. Transport distances are estimated based on southern Sweden conditions. The study is based on BAT (Best available technology). Capital goods are not included. Impacts from production of buildings and infrastructure are not included. Börjesson et al. publishes both a case with allocation and a case with system expansion. In the f3 fuels data project, both these data sets are published.

System Boundaries

Nature Boundary	
Time Boundary	2010 - 2013
Geographical Boundary	Cultivation of sugar beets (assumed on good soil) and handeling and storing of waste and manure is in southern Sweden.
Other Boundaries	
Allocations	Allocation is only done in the ethanol production. The outputs from the ethanol production are ethanol and the by-product pulp. Emissions and primary energy demand are allocated between the ethanol and the pulp. Energy allocation is based on the following energy contents: sugar beet 17,6 MJ/kg, pulp 16,8 MJ/kg
Systems Expansions	No.

Technical system description	This dataset represents a model of the cradle to gate production of ethanol from sugar cane. The following processes are covered: - Cultivation of the sugar cane - Harvest - Distribution to the fuel plant - Production of ethanol - Transportation of ethanol from Brazil to a Swedish port Indirect land use change is considered not to occur, as there are no confirmed links under current situation (Berndes et al, 2010 in Börjesson et al 2010). Data in Börjesson et al. are only published as impact categories and not as emissions except for particles. The amount of primary energy is not mentioned either. Börjesson et al. publishes both a case with allocation and a case with system expansion. In the f3 fuels data project, both these data sets are published.

SPINE LCI dataset: Ethanol from wheat, cradle-to-gate, energy allocation - f3 fuels

Administrative	
Finished	Y
Date Completed	2013-11-30
Copyright	f3 - Swedish Knowledge Centre for Renewable Transportation Fuels
Availability	Public

Technical System	
Name	Ethanol from wheat, cradle-to-gate, energy allocation - f3 fuels
Functional Unit	1 MJ
Functional Unit Explanation	1 MJ output of ethanol from wheat
Process Type	Cradle to gate
Site	

Sector	Fuel
Owner	
Technical system description	This dataset represents a model of the production of ethanol from wheat valid for southern Sweden. The following process are covered: - Cultivation of the wheat - Harvest - Distribution to the fuel plant - Production of ethanol The production of ethanol is assumed to take place at Agroetanol in Norrköping. The mineral fertilizer used is assumed partly to be produced in Western Europe (about 60 %) with present level of cleaning equiptment etc., and partly imported from countries outside Europe (about 40 %). This implies that about 30 % of the mineral fertilizer production takes place in plants with nitrous oxide cleaning where the nitrous oxide emission levels are reduced with about 80 %. All electricity input in the ethanol-plant is Swedish grid mix. Fuel used at the ethanol plant is of forest origin. Allocation is made based on energy content (only case published in "Miljöfaktaboken" (see references), since this allocation method is preferred by the Renewable Energy Directive), however a case with system expansion is made in Börjesson et al. which also has been published in the f3 database. Transport distances are estimated based on southern Sweden conditions. The study is based on BAT (Best available technology). Capital goods are not included. Impacts from production of buildings and infrastructure are not included.

System Boundaries

Nature Boundary	
Time Boundary	2010 - 2013
Geographical Boundary	Cultivation of wheat (assumed on good soil) and handeling and storing of waste and manure is in southern Sweden.
Other Boundaries	
Allocations	Allocation is only done in the ethanol production. For the outputs ethanol and the distillers waste energy allocation was applied. Energy contents: wheat 18,4 MJ/kg, distillers waste 17,3 MJ/kg.
Systems Expansions	No.

SPINE LCI dataset: Ethylene production from cane based ethanol. ESA-DBP

Administrative	
Finished	Y
Date Completed	2009
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public

Technical System	
Name	Ethylene production from cane based ethanol. ESA-DBP
Functional Unit	1 kg of ethylene
Functional Unit Explanation	1 kg of ethylene is needed to produce 1 kg of LDPE which is the object of the study.
Process Type	Gate to gate
Site	Unknown
Sector	Biological
Owner	Unknown
Technical system description	Ethylene production discussed in this study is a one of the steps of sugarcane based LDPE (low density polyethylene) production process. This process is gate-to-gate but the electricity and fuel used in this process are traced back to the cradle. In this step the ethanol is processed into the ethylene. Excerpt from the report: ''The following summarized description of the dehydration of ethanol to ethylene is in accordance to a patent held by Braskem, which was used to model the process in HYSYS and to thereby generate data. (...) The process starts with pumping the ethanol (at 13,73 bar) to the reactor. Before the reactor, the ethanol passes through two heat exchangers. In both exchangers, it is heated by a countercurrent flow of reactor product, which passes the exchangers before undergoing purification. However, before entering the second exchanger the ethanol is mixed with an ethylene-water vapor recycle from the reactor product. Leaving the second heat exchanger this mix is further heated to 481°C in a furnace before entering the adiabatic reactor (at 481°C and 11,93 bar). In the reactor, which is filled with alumina catalyst, the ethanol is dehydrated to ethylene. After an unspecified residence time the stream leaves the reactor and is split in the ratio 2:3 recycle flow to the flow of the end product. The remaining reactor product is further processed to remove impurities and receive PE grade ethylene.''

	This process is included in the system described in: Liptow Ch., Tillman A.-M. (2009). Comparative life cycle assessment of polyethylene based on sugarcane and crude oil. Environmental Systems Analysis, Report 2009:14, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2009--14.pdf Other processes in the CPM Database also included in the above publication: - Sugarcane cultivation. ESA-DBP - Refinery in crude oil based LDPE production process. ESA-DBP - Polymerization in crude oil based LDPE production process. ESA-DBP - Steam cracking in crude oil based LDPE production process. ESA-DBP

System Boundaries

Nature Boundary	Excerpt from the report, see 'Publication': ''Outputs accounted for in this study were by-products and emissions released to air. Water emissions were omitted, because of data unavailability for some parts of the sugarcane route. Energy consumed along the process chain was traced back to the extraction of the energy carriers (fuels) needed for its generation.''
Time Boundary	The data for ethylene production come from the year 2007. Data for energy originated in 2004.
Geographical Boundary	The study was done for Brazil.
Other Boundaries	Excerpt from the report, see 'Publication': ''- patent does not include all processes up to final purification of ethylene (up to polymergrade ethylene) - patent does not state data on how much fuel is internal fuel and how much fuel is external fuel - not possible to receive information with process simulation - use of process simulation up to processes that are given, for other processes and data application of data from Kochar et al. (1981) Assumptions for Kochar et al data: - efficiencies for boilers for external & internal fuels are the same - internal & external fuels are treated as natural gas - all fuel is burned to create steam - in 'crude grade ethylene' scenario all fuel is external fuel - in 'polymer grade ethylene' scenario part of the by-products is burned (internal fuels) to produce steam - energy stated under power is electricity consumed - attributional approach - application of average Brazilian electricity supply mix data - ethylene consumption is based on anhydrous ethanol, simplification set = amount of anhydrous ethanol consumed = amount of hydrous ethanol consumed in this study''
Allocations	No allocation needed.
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	2007
Data Type	Derived, unspecified
Represents	See 'Function'
Method	Excerpt from the report: ''As already stated in the process description the data applied to assess this process partly originate from a patent held by Braskem(...). It was simulated in the process simulation program Aspen HYSYS. However, this patent does not include all steps up to the final purification of the ethylene. For this reason, the data generated from the process simulation were combined with data from a text released by Kochar et al. (1981). The text states the complete energy (in the form of electricity and fuels burned directly for the process) consumed to produce polymergrade PE as well as the specifications of the ethanol consumed - application of anhydrous ethanol. The energy consumed in the process is electricity and fuels directly burned for process purposes. Electricity consumed was assessed using the already stated data - see electricity consumption. All other energy carriers directly used in the plant were assumed to be natural gas. They were assessed according to data from Bargigli (2004) for the natural gas extraction and according to Baumann and Tillman (2004) for their combustion.

About Inventory	
Publication	Liptow Ch., Tillman A.-M. (2009). Comparative life cycle assessment of polyethylene based on sugarcane and crude oil. Environmental Systems Analysis, Report 2009:14, ISSN:1404-8167. Chalmers University of Technology. Gothenburg, Sweden. Link to PDF: http://cpmdatabase.cpm.chalmers.se/DataReferences/ESA_2009--14.pdf
Intended User	LCA practitioner
General Purpose	Excerpt from the report, see 'Publication': ''The goal of this study is to answer the question, is the use of sugarcane based LDPE in the production of goods and packing in Sweden environmentally preferable to crude oil based LDPE.''
Detailed Purpose	Ethylene production is a step in the production process of sugarcane based LDPE so it was necessary to investigate the environmental load of it.
Commissioner	Unknown - .
Practitioner	Christin Liptow & Anne-Marie Tillman - Environmental Systems Analysis, Chalmers University of Technology.
Reviewer	Tillman, Anne-Marie - Environmental Systems Analysis, Chalmers University of Technology
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries' above
About Data	ESA database project. Years 2009-2011. Administrating organization: Chalmers University of Technology, Department of Environmental Systems Analysis. Financier: The Swedish Research Council (Vetenskapsrådet) Data documentor: Katarzyna Iwanek assisted by Filippa Fuhrman (ESA) and Johan Tivander (ESA). Review committee for imported data: Johan Tivander (ESA), Emma Rex (CPM, Center for environmental assessment of Product and Material Systems), Bengt Steen (ESA), Anne-Marie Tillman (ESA).
Notes	Ethylene production is a step in a production process of sugarcane based LDPE which was the object of the study. The production process starts with cane cultivation, ethanol production, ethylene production, polymerization, use phase (which is not included in the study) and ends with incineration. In the study sugarcane based- was compared with oil based- LDPE. NB: in the report two approaches were investigated: attributional and consequential. For consequential approach see the report.

SPINE LCI dataset: European average production of sodium carbonate (Solvay process)

Administrative	
Finished	Y
Date Completed	2003-03-10
Copyright	

Availability	Public

Technical System

Name	European average production of sodium carbonate (Solvay process)
Functional Unit	1 ton of Na_2CO_3 (sodium carbonate).
Functional Unit Explanation	1 ton of sodium carbonate produced at the plant.
Process Type	Gate to gate
Site	Europe
Sector	
Owner	Europe
Technical system description	This activity describes the average production of sodium carbonate in Germany. The data represent average results for Western European soda production. The sodium carbonate is produced using the Solvay technique. The production process consists of the following steps: 1. brine cleaning, 2. manufacture of the product, 3. lime milk preparation, 4. NH3-recovery. The detailed description of each stage of the process is presented below. 1. SODIUM CARBONATE PRODUCTION (SOLVAY TECHNIQUE) The technical manufacture of soda (i.e. sodium carbonate) with the Solvay Technique is effected by the conversion of sodium chloride (salt) and calcium carbonate (limestone) according to the following reaction. (1) 2 NaCl + $CaCO_3$ ====> $CaCl_2$ + Na_2CO_3 Besides soda, the Solvay Technique also produces $CaCl_2$ as a by-product. The overall process can be divided into the following reaction steps: 1.1. Brine cleaning. a) Precipitation of magnesium hyfroxide and calcium carbonate by the addition of lime milk and soda solution into the brine: (2) Mg^{2+} + $Ca(OH)_2$ ====> $Mg(OH)_2$ + Ca^{2+} (3) Ca^{2+} + Na_2CO_3 ====> $CaCO_3$ + Na^{2+} 1.2. Manufacture of the product. a) Precipitation of the relatively heavy-soluble bicarbonate ($NaHCO_3$) by the addition of carbonic acid into a salt solution saturated with ammonia: (4) NaCl + H_2O + NH_3 + CO_2 ====> NH_4Cl + $NaHCO_3$ b) Thermic decomposition of the bicarbonate: (5) 2 $NaHCO_3$ ====> CO_2 + H_2O + Na_2CO_3 1.3. Lime milk preparation. a) Manufacture of caustic lime: (6) $CaCO_3$ ====> CaO + CO_2 b) manufacture of lime milk: (7) CaO + H_2O ====> $Ca(OH)_2$ 1.4. NH3-Recovery. a) Recovery of ammonia by distillation of ammonium chloride containing mother liquor and lime milk: (8) 2NH_4Cl + $Ca(OH)_2$ ====> 2NH_3 + 2H_2O + $CaCl_2$ 2. RAW MATERIALS FOR SODIUM CARBONATE PRODUCTION 2.1. Limestone. 2.2. Sodium chloride production. Sodium chloride exists naturally as salt deposits of varying purity. One method to extract sodium chloride is brine pumping. Water is pumped into a natural slat deposit when the slat dissolves to produce a sturated solution which may then be pumped to the surface for use. The main impurities present are magnesium, calcium and sulphate ions with a total typical concentration of 0,6 wt%. Another way of producing sodium chloride is rock salt mining. The impurities are similar to the process described above. 2.3. Ammonia production. Ammonia is mainly produced by the direct reaction of nitrogen with hydrogen. The usual source of hydrogen is from the steam reforming of natural gas. Air may be added to provide the nitrogen needed to produce ammonia.

	3. HEAT The fuels used in steam production vary widely from low grade lignite and brown coal through to natural gas, hydrogen (in some electrolysis plants), electricity (in countries where there is an abundant supply of cheap hydropower) and, in some instances, waste products from the production process itself. Data for this activity are the resulting average of all steam plants that have been examined in the course of the work by APME on chemicals and plastics, i.e. 215 plants. 4. ELECTRICITY Throughout the whole gate to gate inventory, electricity is required (710 MJ, i.e. 197.2 kWh). Information about electricity internal flows is given below: Electricity - biomass 3,8656 kWh Electricity - coal 55,7749 kWh Electricity - geo 0,9072 kWh Electricity - hydro 25,6785 kWh Electricity - natural gas 26,0335 kWh Electricity - nuclear 69,9947 kWh Electricity - oil 14,3382 kWh Electricity - wind 0,6614 kWh Literature reference: Final Report ''German Notes on BAT for the Production of Large Volume Solid Inorganic Chemicals. Soda''. Institut für Umwelttechnik und Management and der Universität Witten/Herdercke, UBA, June 2001. For more references see: ''About data''

System Boundaries

Nature Boundary	Environmental impact due to use of machinery, plants and infrastructures is not included. Consumption of energy and raw material resources as well as emissions to air and water are included.
Time Boundary	Data on sodium carbonate production were published in 2001. Data on heat and electricity production are from 1997.
Geographical Boundary	All scenarios are supposed to be situated in any Western European country.
Other Boundaries	Transportation of fuels to vehicles or energy plants is not included.
Allocations	Not applicable
Systems Expansions	Not applicable

About Inventory

Publication	Final Report ''German Notes on BAT for the Production of Large Volume Solid Inorganic Chemicals. Soda''. Institut für Umwelttechnik und Management and der Universität Witten/Herdercke, UBA, June 2001. --- Data inserted by: Jose Canga Rodrigues, Chalmers University of Technology and Akzo Nobel Surface Chemistry AB. Data reviewed by Karolina Flemström, Industrial Environmental Informatics, Chalmers University of Technology. Published in SPINE@CPM 2003-05-28
Intended User	Chemical producing industry, L
General Purpose	The purpose is to estimate the emissions and raw materials needed for the production of sodium carbonate (Solvay Technique) on an average basis for Europe.
Detailed Purpose	To be included in LCA studies where sodium carbonate is used but no data from the supplier are available. This dataset was used in the Master of Science thesis work ''Life Cycle Assessment of Wood-Based Ethanol-Diesel Blends (E-Diesel). Jose Canga Rodrigues. Chalmers University of Technology and Akzo Nobel Surface Chemistry AB. Sweden. 2003. The aim of the study was to evaluate low ethanol-content diesel blends (E-diesel) used as automotive fuel.
Commissioner	- Akzo Nobel Surface Chemistry AB 444 85 Stenungsund Sweden.
Practitioner	Canga Rodríguez, José - Akzo Nobel Surface Chemistry S-44485 Stenungsund SWEDEN.
Reviewer	Manuilova, Anastassia - Akzo Nobel Surface Chemistry AB Enironmental Development S-44485 Stenungsund Sweden
Applicability	Applicable to Western European sodium carbonate suppliers, who produce soda following the Solvay Technique.

About Data	SODIUM CARBONATE PRODUCTION Data based on the average production of sodium carbonate in Germany and represent soda production in Western European countries. Data come from a study carried out by the German Environmental Agency. [UBA, 2001] ELECTRICITY Average electricity production in EU nations, namely Austria, Belgium, Denmark, Finland, France, Germany, Greece, Ireland, Italy, Luxembourg, the Netherlands, Portugal, Spain, Swedem and the United Kingdom. [DG XVII, 1999] REFERENCES ''Annual energy review'', Directorate General for Energy (DG XVII), 1999 Final Report ''German Notes on BAT for the Production of Large Volume Solid Inorganic Chemicals. Soda''. Institut für Umwelttechnik und Management and der Universität Witten/Herdercke, UBA, June 2001.
Notes	This data set was used in the Master of Science thesis work ''Life Cycle Assessment of Wood-Based Ethanol-Diesel Blends (E-Diesel). Jose Canga Rodrigues. Chalmers University of Technology and Akzo Nobel Surface Chemistry AB. Sweden. 2003.

SPINE LCI dataset: European Union, electricity generation mix 1998

Administrative	
Finished	Y
Date Completed	2001-01-31
Copyright	IEA
Availability	Public

Technical System	
Name	European Union, electricity generation mix 1998
Functional Unit	Total electricity produced during 1998
Functional Unit Explanation	The electricity mix refer to the total amount of electricity generated by different power sources expressed in GWh during the year 1998.
Process Type	Unit operation
Site	EU countries
Sector	Energyware
Owner	EU countries
Technical system description	The generation of electricity with different power generating systems in the European Union countries during the year 1998. The EU includes Austria, Belgium, Denmark, France, Finland, Germany, Greece, Ireland, Italy, Luxembourg, Netherlands, Portugal, Spain, Sweden and United Kingdom.

System Boundaries	
Nature Boundary	Not applicable, since the data only refer to the electricity generation mix. The environmental load for generation of electricity is not included.
Time Boundary	The data refer to 1998.
Geographical Boundary	Only electricity produced in Australia is considered. Import or export of electricity is not included.
Other Boundaries	-
Allocations	Not applicable
Systems Expansions	Not applicable

Flow Data

General Activity QMetaData

Date Conceived	1998
Data Type	Derived, statistics
Represents	This scenario represents the average production of sodium carbonate in Germany.
Method	The data are collected from IEA Statistics.
Literature Reference	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8, page II.300.
Notes	See ''Represents'' for each flow to see which power generation system that are used to generate the electricity.

About Inventory

Publication	IEA Statistics, Energy statistics of OECD countries 1997-1998, 2000 Edition, ISBN 92-64-05914-8. -- Data documented by: Caroline Setterwall, Swedpower, Vattenfall AB, Sweden Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Sweden --
Intended User	LCA practitioners
General Purpose	The data is intended to be used as basis when calculating the environmental load from electricity production in OECD countries/regions.
Detailed Purpose	The specific aim for documenting the IEA statistics about electricity generation mixes in the OECD countries/regions is to supply EPD-practitioners with general LCA-data for electricity generation to be used in absence of specific data in accordance with the directions of Miljöstyrningsrådet (The Swedish Environmental Management Council) and the Swedish EPD-guidelines.
Commissioner	Birgit Bodlund - Vattenfall Elproduktion AB, Stockholm, Sweden .
Practitioner	Setterwall, Caroline - SwedPower AB, Stockholm, Sweden .
Reviewer	CPM -

Applicability	The environmental load may be calculated using the electricity generation mix together with LCI-data describing electricity production of different power generating systems. The power sources is found in ''Represents'' in QMetaData for each specific flow. When the electricity generation mix is used as general LCA data for the Swedish EPD system, the following data sets should be used in the calculations: - Biofuel electricity energy system, EPD-version - Fuel gas electricity energy system, EPD-version - Hydro electricity energy system, EPD-version - Lignite electricity energy system, EPD-version - Nuclear electricity energy system, EPD-version - Oil electricity energy system, EPD-version - Stone coal electricity energy system, EPD-version - Wind electricity energy system, EPD-version The following countries and regions have been documented in the database: Australia, electricity generation mix 1998 Austria, electricity generation mix 1998 Belgium, electricity generation mix 1998 Canada, electricity generation mix 1998 Czech Republic, electricity generation mix 1998 Denmark, electricity generation mix 1998 European Union, electricity generation mix 1998 Finland, electricity generation mix 1998 France, electricity generation mix 1998 Germany, electricity generation mix 1998 Greece, electricity generation mix 1998 Hungary, electricity generation mix 1998 Iceland, electricity generation mix 1998 Ireland, electricity generation mix 1998 Italy, electricity generation mix 1998 Japan, electricity generation mix 1998 Korea, electricity generation mix 1998 Luxembourg, electricity generation mix 1998 Mexico, electricity generation mix 1998 Netherlands, electricity generation mix 1998 New Zealand, electricity generation mix 1998 Norway, electricity generation mix 1998 OECD Europe, electricity generation mix 1998 OECD North America, electricity generation mix 1998 OECD Pacific, electricity generation mix 1998 OECD total, electricity generation mix 1998 Poland, electricity generation mix 1998 Portugal, electricity generation mix 1998 Spain, electricity generation mix 1998 Sweden, electricity generation mix 1998 Switzerland, electricity generation mix 1998 Turkey, electricity generation mix 1998 United Kingdom, electricity generation mix 1998 United States, electricity generation mix 1998
About Data	
Notes	-- --- Changes made to the data set after publishing in SPINE@CPM--- >>> 22 October 2001: <<< Changes made by Ann-Christin Pålsson, CPM: The electricity production by hard coal, coke oven and blast furnace gas have been corrected from 476575 GWh to 501709 GWh according to the original report. The error was identified and reported by Gunnar Mattson, ABB Corporate Research.

SPINE LCI dataset: Exterior coating (Swedish red paint) maintenance. ESA-DBP

Administrative	
Finished	Y
Date Completed	1999
Copyright	Environmental Systems Analysis, Chalmers Univ. of Technology
Availability	Public.

Technical System

Name	Exterior coating (Swedish red paint) maintenance. ESA-DBP
Functional Unit	1 m2 * year
Functional Unit Explanation	1 m2 of Swedish red paint maintained over one year.
Process Type	Gate to gate
Site	Not applicable
Sector	Activities of households as employers
Owner	Not applicable
Technical system description	Maintenance of the exterior coating Swedish red paint. Data includes the production process, the manufacture and assembling of wooden cladding and painting, repainting and removal when necessary. This process is included in the system described in: Blanco-Rosete S. R., 2002, LCA data structure and time series related to construction and maintenance in Sweden. Environmental Systems Analysis report 2002:14, Chalmers University of Technology, Gothenburg, Sweden Other processes in the CPM Database also included in the above publication: Swedish red paint manufacturing and application. ESA-DBP Clay roof tile manufacturing. ESA-DBP Pine window production. ESA-DBP Floor maintenance. ESA-DBP

About Inventory	
Publication	Blanco-Rosete S. R., 2002, LCA data structure and time series related to construction and maintenance in Sweden. Environmental Systems Analysis report 2002:14, Chalmers University of Technology, Gothenburg, Sweden
Intended User	LCA practitioners.
General Purpose	This process data set is recalculated to fit in the Master Thesis given in 'Publication'. Excerpt from the report (see 'Publication'): ''Construction, building maintenance and housing management contribute to a large extent to the environmental impact. When housing owners and managers perform their activities they should be aware of the environmental effects they cause. The environmental impact of existing houses could be addressed and diminished within the possibilities of a clever management.''
Detailed Purpose	Excerpt from the report (see 'Publication'): ''This master thesis descibes and defines a building system model for a multi-family house in Gothenburg over a 30 year period from 1970 to 2002 . The model was used to collect environmental impact information regarding materials or products used in the construction and maintenance of a building . The environmental impact ofa a multi-family house was evaluated through a Life Cycle Assessment (LCA). Finally to account the long sevice lifetime of a multi-family house two case studies were carried out to test if the use of Time series can illustrate the environmental impact of maintenance activities caused by decisionmaking in housing management.''
Commissioner	Not applicable - .
Practitioner	Sergio R. Blanco-Rosete - .
Reviewer	Birgit Brunklaus - Environmental Systems Analysis
Applicability	For applicability for the process see 'Technical System' and 'System Boundaries'.
About Data	Excerpt from the report (see 'Publication'): ''The results are originally presented for a 100 years time period and per square meter. When the calculations were performed the original data was modified to fit according to the funcional unit of this study.'' ESA Database Project. Years: 2009-2011. Documentation completed for this data set: 2010-09-21 Administering organisation: Chalmers University of Technology, the division of Environmental Systems Analysis. Financier: The Swedish Research Council. Documentor of data: Filippa Fuhrman (ESA). SPINE LCI dataset: Extraction and beneficiation of rock phosphate

Administrative	
Finished	Y
Date Completed	99-01-25
Copyright	
Availability	Public

Technical System	
Name	Extraction and beneficiation of rock phosphate
Functional Unit	1 kg of commercial rock phosphate (32 % P2O5)
Functional Unit Explanation	
Process Type	Other
Site	
Sector	Metal and mineral mining
Owner	
Technical system description	Exactly what techniques the data represents in this dataset is uncertain as the data are average values from literature. No specific mining site has been studied. The text below gives generic information about extraction and beneficiation of rock phosphate. For further information on interpretations of what the data represent, see ''method'' in flow meta data window. Extraction of Rock Phosphate There are some 200 minerals containing more than 1 % of P2O5 (it is common to give the concentration of P in its fully oxidised form, P2O5), but the most important for the phosphoric acid industry are the apatite minerals of which the most commonly encountered are: Francolite - Ca10(PO4)6-x(CO3)x(F/OH)2+x Fluorapatite - Ca10(PO4)6(F/OH)2 There are two main types of apatite deposits: sedimentary and igneous. Fluorapatite predominates in igneous phosphate rock and francolite predominates in sedimentary phosphate rock (BAT N° 4, 1995). Sedimentary deposits are the most common origin for phosphate rock production. Both sedimentary and igneous rocks are associated with a large number of impurities. The largest sedimentary rock mining areas are found in Florida and Morocco, while igneous rock is mined in Russia (Kola), South Africa, Brazil and Finland. Compared to igneous rocks, sedimentary rocks contain more carbonates and fluorides and usually more aluminium and iron (Becker, 1989). Sedimentary rocks also contain a much higher amount of cadmium than igneous rocks do (Ullmann, vol. A 19, 1991). On the other hand, igneous rock normally has a lower P2O5 content. Therefore, mining of igneous rock uses larger mining area and produces more waste rock than mining of sedimentary rock does (Serviö pers. comm., 1998). Mining of phosphate rock is done either by open cast mining or underground mining. Approximately five tonnes of ore must be mined and beneficiated to produce one tonne of commercial phosphate rock with an average P2O5 content of 32 % (Ullmann, vol. A 19). Open cast mining consists of removing the overburden covering the phosphate bed and recovering the ore by mechanical shovels or by hydraulic methods. Economic conditions can allow up to 1.5-2 m3 of material to be removed per tonne reclaimed ore. When the overburden is too large under ground mining has to be chosen. This has been done in for example, Tunisia, Jordan and Egypt and for the igneous Kola rock in Russia (Becker, 1989). The mining, crushing and grinding of the phosphate ore are very energy intensive unit operations in rock phosphate processing. Size reduction is necessary because most mineral processing/separation methods require the ore to be of a certain size. Large quantities of energy are needed because most of the energy input is absorbed by the machine itself in vibration, generation of heat etc. and only part of the energy is available for breaking the rock. The energy required per unit mass increases rapidly as the desired particle size decreases. (Kirk-Othmer, vol. 16, 1995) Beneficiation of the Phosphate Ore Beneficiation or upgrading of the phosphate ore has called for a number of different techniques. In some favourable cases, only screening and drying is necessary to reach a commercial grade of about 30 % P2O5. However, in most cases the ore quality needs removal of impurities. For sedimentary rock, suitable techniques for economic ore concentration are crushing and screening or grinding, followed by pneumatic particle size selection and washing by hydrocyclones or classifiers. These techniques are based on particle size selection. The phosphate ore particles usually occur within particle size ranges between 60-80 mm and 1000-1400 mm (Becker, 1989).

	An ore concentration technique applied most often with igneous phosphate ore is flotation. It can be used when silica has to be removed from the ore. However, calcite ($CaCO_3$), a very frequent by-product from phosphate ore processing, is difficult to separate by flotation (Becker, 1989). Calcination (roasting) is another technique for the beneficication of phosphate ore. Although not frequently used it is sometimes selected to destroy calcite ($CaCO_3$). But even though CO_2 is released, CaO remains in the ore and is not easy to leach out by washing. Calcination also destroys organics and therefore prevents foaming in the later chemical rock treatment. Phosphate rock calcination usually reduces the original qualities of the ore in terms of phosphoric acid production (filtration rate). The changes, however, seem to affect the ore differently depending on the amount of CO_2 removed by the calcination. Consequently, rocks containing a large amount of CO_2 are more affected. (Becker, 1989) The process of mining and beneficiation to produce one ton of commercial rock phosphate (32 % P_2O_5) requires approximately 0.9 GJ/tonne rock or 2.9 GJ/tonne P_2O_5. If the rock is calcined the total energy requirement is doubled (Ullmann, vol. A 19, 1991). References: BAT N° 4 (1995). System Boundaries

Nature Boundary	The system starts with extraction of rock phosphate and ends with commercial rock phosphate leaving the beneficiation site. Emissions and use of resources due to the production and combustion of steam and diesel are not included.
Time Boundary	The literature from which data are taken from is published in 1996 and 1998.
Geographical Boundary	Europe.
Other Boundaries	
Allocations	Not applicable.
Systems Expansions	Not applicable.

Flow Data

General Activity QMetaData

Date Conceived	
Data Type	Derived, unspecified
Represents	See 'Function'.
Method	There are two different types of origins for phosphate ore: igneous rock and sedimentary rock. The energy requirement for production of dry sedimentary phosphate rock is as low as 0.1 GJ/t rock phosphate (32 % P_2O_5) for the easiest rock to be upgraded. Mining of igneous rock requires higher energy consumption. As igneous rock is used to some extent for production of fertilisers in Western Europe the average number is assumed to be 0.9 GJ/t (Kongshaug, 1998). This figure correlates well with figures given by EFMA (1998) and Patyk (1996) and has also been chosen to be representative for production of fertilisers used in Western Europe. This value for energy consumption may be somewhat high when taking the considerable amount of import into account, since a large part of this import is of sedimentary origin. When it comes to partitioning the energy consumption between different energy sources, figures from Kongshaug (1998) and Patyk (1996) have been taken into account. According to Patyk (1996) there is a partition between the different energy sources diesel, steam and electricity for extraction of the rock phosphate used in Germany. This partition has been assessed to be representative for the rest of Western Europe as well. The resulting figures using the partitioning in Patyk (1996) and the total energy figure in Kongshaug (1998) are as follows; 0.23 GJ diesel/t rock phosphate, 0.47 GJ steam/t rock phosphate and 0.21 GJ electricity/t rock phosphate. Steam has been assumed to be produced by combustion of oil. Data for the amount of waste generated from producing rock phosphate is taken from EFMA (1998). Five tonnes of phosphate ore must be mined and benificiated to produce one tonne of commercial rock (32% P_2O_5).

About Inventory

Publication	Davis J, Haglund C (1999). ''Life Cycle Inventory (LCI) of Fertiliser Production - Fertiliser Products Used in Sweden and Western Europe''. SIK report no. 654. The Swedish Institute for Food and Biotechnology (SIK). Gothenburg, Sweden. --- Data documented by: Jennifer Davis, SIK (The Swedish Institute for Food and Biotechnology). Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology ---
Intended User	The data are intended to be us
General Purpose	To generate an inventory of emissions and use of resources for the production of fertilisers used in Sweden and Western Europe.
Detailed Purpose	The purpose was not to compare production of different fertilisers to each other but to generate a thorough inventory of emissions and use of resources due to the production of fertilisers used in Sweden and Western Europe. The data are intended to constitute a useful basis of input information in life cycle assessments of food production systems. Extraction and beneficiation of rock phosphate is one step in the line of production of fertilisers containing phosphorus.
Commissioner	- SIK AB, The Swedish Institute for Food and Biotechnology Box 5401 SE-402 29 Gothenburg Sweden .
Practitioner	Davis, Jennifer and Caroline Haglund - SIK AB Box 5401 402 29 Gothenburg Sweden.
Reviewer	-
Applicability	Applicable for extraction and beneficiation of rock phosphate in Europe. The data are intended to be used in life cycle assessments of fertiliser production. The dataset is included in aggregated datasets for production of fertilisers at Hydro Agri AB in Köping and in aggregated datasets for production of fertilsers used in Western Europe containing phosphorus (cradle to gate).
About Data	Data are gathered from literature, i.e. no specific extraction site has been studied.
Notes	Internal review of the report was performed by: Olle Ramnäs, CTH (Chalmers University of Technology), Berit Mattsson and Magnus Stadig, SIK (The Swedish Institute for Food and Biotechnology).

SPINE LCI dataset: Extraction and grinding of dolomite

Administrative

Finished	Y
Date Completed	1999-01-25
Copyright	
Availability	Public (flow data are confidential and not included).

Technical System	
Name	Extraction and grinding of dolomite
Functional Unit	1 kg ground dolomite
Functional Unit Explanation	
Process Type	Other
Site	Sweden
Sector	Other mining
Owner	Sweden
Technical system description	The dolomite is extracted by open-pit mining demanding 5-10 times less energy than underground mining.

System Boundaries	
Nature Boundary	The system starts with extraction of dolomite and ends with ground dolomite leaving the factory gate. Emissions from production of electricity and production and combustion of diesel are not included.
Time Boundary	The figures were given in 1998.
Geographical Boundary	The extraction and grinding of dolomite takes place in Sweden.
Other Boundaries	Emissions and use of resources due to the production and combustion of diesel and production of electricity are not included in the system.
Allocations	Not applicable.
Systems Expansions	Not applicable.

Method	There are two different types of origins for phosphate ore: igneous rock and sedimentary rock. The energy requirement for production of dry sedimentary phosphate rock is as low as 0.1 GJ/t rock phosphate (32 % P2O5) for the easiest rock to be upgraded. Mining of igneous rock requires higher energy consumption. As igneous rock is used to some extent for production of fertilisers in Western Europe the average number is assumed to be 0.9 GJ/t (Kongshaug, 1998). This figure correlates well with figures given by EFMA (1998) and Patyk (1996) and has also been chosen to be representative for production of fertilisers used in Western Europe. This value for energy consumption may be somewhat high when taking the considerable amount of import into account, since a large part of this import is of sedimentary origin. When it comes to partitioning the energy consumption between different energy sources, figures from Kongshaug (1998) and Patyk (1996) have been taken into account. According to Patyk (1996) there is a partition between the different energy sources diesel, steam and electricity for extraction of the rock phosphate used in Germany. This partition has been assessed to be representative for the rest of Western Europe as well. The resulting figures using the partitioning in Patyk (1996) and the total energy figure in Kongshaug (1998) are as follows; 0.23 GJ diesel/t rock phosphate, 0.47 GJ steam/t rock phosphate and 0.21 GJ electricity/t rock phosphate. Steam has been assumed to be produced by combustion of oil. Data for the amount of waste generated from producing rock phosphate is taken from EFMA (1998). Five tonnes of phosphate ore must be mined and benificiated to produce one tonne of commercial rock (32% P2O5).

Intended User	LCA practitioners.
General Purpose	This data set is included in a master thesis. Excerpt from the master thesis abstract: ''Hydrogen is often considered as the way out of the environmental and economical problems associated with the use of fossil fuels. However, one of the main implementation barriers is the missing infrastructure. The introduction of hydrogen-blended compressed natural gas (HCNG) as a fuel for natural gas vehicles could serve as a bridging technology by using the existing natural gas infrastructure for the distribution of hydrogen.''
Detailed Purpose	Excerpt from the master thesis abstract: ''The purpose of this thesis is to assess and compare the environmental aspects of using natural gas, HCNG with 15% and 30% hydrogen by volume, and hydrogen as vehicle fuels within the scope of the proposed demonstration project.'' Excerpt from the report (see 'Publication'): ''Data for the production and distribution of natural gas is taken from the “Environmental factbook for fuels” (Uppenberg et al. 2001) published by the Swedish Environmental Research Institute (IVL). Their calculations are based on Sydkraft's LCA report “Environmental impact from Sydkraft's electricity production 1999” (Hansson et al. 2000), which is recommended by the IVL due to its high quality.''

Technical System

Name	Extraction of crude oil
Functional Unit	1 kg
Functional Unit Explanation	1 kg crude oil.
Process Type	Cradle to gate
Site	North Sea
Sector	Crude oil and natural gas extraction
Owner	North Sea
Technical system description	The system includes extraction of crude oil in the North Sea. The extraction of crude follow the technique of tertiary extraction, where steam or carbon dioxide is injected in the oil reservoir to draw up the oil. The emissions to air consist predominantly of carbon dioxide and mostly derive from energy production on the platforms. The energy is used for operations such as transporting the oil ashure by pipeline and injecting wather and gas into the reservoirs. The rest of the emissions come from flaring of gas and some diffuse emissions. The emissions of oil to water comes from four sources: - The largest oil emission into water comes from the drilling mud during the actual drilling process. -From the reservoir a mixture of oil, gas and water comes. These are separated. The water is cleansed and then discharged into the sea. This water contains small amounts of oil. - In order to empty the tankers of oil, water is pumped in. When the water later on is discharged into the sea it contains small amounts of oil. - The last source consist of unforeseen oil emissions.

System Boundaries

Technical System

Name	Extraction of crude oil and gas
Functional Unit	1 Mega Tonne
Functional Unit Explanation	1 Mega Tonne produced crude oil and gas. 78,6% Crude oil and 21,3% gas.
Process Type	Cradle to gate
Site	Norway
Sector	Crude oil and natural gas extraction
Owner	Norway
Technical system description	The system involves extraction of offshore crude oil and (natural) gas in Norway and all Norwegian sites are included. The production therefore follows Norwegian standard concerning legislation and environmental policy. In the system the following operations are included: Production drilling, Well steam processing, Produced water removal, Pressure maintenance, Oil and gas metering, Flaring and venting, Power supply systems, Support and safety

systems and transportation of the crude oil and natural gas to the main land.

Below a more detailed description is given of the system.

PRODUCTION DRILLING

Drilling and casting of production wells

Production wells can be drilled either from the production platform, requiring the platform to be equipped with full drilling facilities of from a mobile production unit, which predrills platform wells and subsea completed wells. Current drilling technique enables the wells to be drilled with exact deviation any direction, even horizontally, from the drilling installation. This enables
several wells to be drilled from the same platform.

Drilling Equipment

The main equipment required for drilling a well are:
Drill string and bit
Well casting
Drilling derrick
Hoisting equipment
Blow-out preventer

The drill string is a heavy walled hollow pipe through which drilling fluids are pumped while the string rotates and turns the drill bit and maintains the pressure on the drill bit while it is cutting.

The well casting prevents the walls of the well from collapsing or leaking. When a new casting length is being drilled, the formation pressure is balanced by increasing the density of the drill fluid by adding barite (bariumsulphate), a heavy, insoluble salt. Handling the drill string and casting requires specialised heavy duty hoisting equipment which is provided by the drill tower (derrick).

The blowout preventor (BOP) is a safety device used during drilling and other well operations. Its main function is to ensure that the well can be shut down at any time. The BOP is an arrangement of independent valves that are placed on the top of the wallhead. The BOP can create a tight seal around the drill string in an emergency situation actually shear the drill string and close in the well.

Drilling a well can take from a few weeks to several months or even longer if complications should arise during the operations.

Drill Chemicals, Mud and Cutting Treatment System

The drill fluid has a number of functions and contains chemical components which:
Lubricates the drill string
Cools and cleans the drill bit
Balances the formation pressure
Stabilises the well bore and
Carries the drill cuttings out of the well

The composition of the drilling fluid is adjusted to meet changing needs as the well penetrates the various formations. A drilling fluid circulation system typically consists of a tank for mixing additives, circulation pump(s), and equipment for separating fluid and drill cuttings from the fluid returned from the well. Drilling conditions determines the type of cutting fluid to be used. It is common to divide the drilling fluids in two main groups; water based and oil based fluids.

A water miscible drilling fluid consists of a continuos water phase with dissolved salts, polymers, dispersed clay and a weighting material (such as barite).

The water immiscible drilling fluid is in general a water-in-oil emulsion with despersed clay and weighting material. Oil based drilling fluids have some operational advantages over water based fluids, because they need less chemical additives and create less drilling waste. While water based drilling fluids become increasingly contaminated during use, oil based drilling fluids only interact to a small extent with the drill cuttings and may therefore be recycled for reuse.

The rock-cuttings, from a well, contain traces of drilling fluids and chemicals. In the case of water based fluids, the cuttings are commonly discharged untreated to the sea. Oil contaminated cuttings are not permitted to be discharged to the sea. The oil-contaminated wastes are transported to shore for treatment and disposal. The oil contaminated fluid has a certain heat value and is often disposed of by thermal incineration. Reinjection of the drilling waste into a well for subsurface storage is being tested with promising result.

Well Completion

When the drilling of production well is finished, the well is then completed for production. The completion process includes the installation of a production string that carries the well fluid from the reservoir up to the processing facilities on the platform. An arrangement of valves often referred to as the Christmas tree, replaces the BOP on the top of the wall head. The Christmas tree can sit on either the platform deck in the case of a fixed platform of a subsea template.

WELL STEAM PROCESSING

Gas fields produce varying amounts of condensed hydrocarbons and water that have to be separated from the gas prior to export. Oil fields also contain some associated gas. Most of the oil fields on the Norwegian continental shelf also produce formation water. The amount of produced water normally increases as the oil reserves are depleted. Oil fields that are in the mature production stage may contain up to90% water in the produced steam.

The main reasons for oil and gas production are:
1. to separate the oil, gas and water to obtain an oil product with sufficiently low vapour pressure to enable oil transportation by pipeline using export pumps or direct offshore loading to a crude tanker.
2. to remove water and higher hydrocarbons from the gas phase to avoid multiphase flow conditions and hydrate formation.
3. to reduce water content for equipment corrosion protection
4. to meet gas and oil sales specifications

Several stages of oil and gas separation may be required depending on factors, such as:

composition of the well-steam
oil to gas ratio
requirements indicated by the type of export systems

As a result each field will have its own tailor made processing system. The processing system can be anything from a simple oil and gas separation to a complex multistage separation, dew point control and compression system.

All gas produced on the Norwegian continental sheft is exported by pipelines. Oil is either exported by pipelines or loaded directly into oil tankers on the field. In the latter case, a local storage facility is provided.

PRODUCED WATER REMOVAL

Separating the produced water from the oil is accomplished through a phase separation. The gas is normally dehydrated by triethylene glycol (TEG) in an absorption tower. The wet glycol is the regenerated in a heater before being recycled back to the absorption tower.

Produced Water Treatment System

After being separated from the oil/gas/water separators, the produced water is routed to a water cleaning system for removal of dispersed oil droplets before being discharged to sea. The treatment system removes most of the residual oil from the water. Several technologies are being used and technology improvements are gradually taking place. Separation in hydrocyclones is currently considered to be the most cost efficient technology for removing dispersed oil from produced water.

Some of the production chemicals added to the processing system, and many of the natural components dissolved in the produced water will be discharged to sea with the produced water.

PRESSURE MAINTENANCE

Some oil reservoirs maintain their pressure throughout the field production life due to natural water drive. On other oil fields the reservoir pressure declines as the field is depleted. Artificial pressure maintenance is possible on some of the fields by means of sea water or gas injection. Gas injection and seawater injection systems are installed on these fields.

High-pressure gas injection requires the gas to be injected into the gas cap of the oil reservoir through a dedicated injection well or an abandoned gas production well. Water injection wells are purpose-drilled. The injection medium, seawater is filtered in order to reduce the content of particles that may plug the reservoir formation. Dissolved oxygen is removed from the water in order to avoid corrosion, and chemicals are added to control scaling, algae and bacteria growth that may also plug the reservoir.

OIL AND GAS METERING

Fiscal measurements of the oil and gas production form the basis for income and tax revenues. Separate oil and gas metering systems are installed for every field.

FLARING AND VENTING

Facilities for flaring of the gas to depressurise the oil and gas processing facilities are installed as a safety precaution on all production platforms. The flare system consists of a pressure relief system and a flare tower or a long inclined boom. The boom provides protection from the heat and fire by increasing the distance between the flame and any other part of the installation.

Due to the lack of export facilities or a local gas market, flaring is still being used to burn off natural gas produced together with oil in some areas of the world. But in Norway flaring is only allowed when it is used for safety reasons. Some flaring may also occur during start-up, well operations, process upsets, blow-down and maintenance operations.

Small amounts of hydrocarbon gases are vented directly to the air from parts of the production processing line. There are several sources for these continuos and non-continuos emissions.

stripping gas from glycol regeneration
gas turbine start-up gas (on old platforms only)
venting, purge and blanket operations
fugitive emissions
compressor system seal leakage

The amount of gas venting is much lower on modern platforms than on the older ones.

POWER SUPPLY SYSTEMS

Gas turbines are used for power generation on production platforms, while diesel engines are used on mobile installations. Electrical cable connections from the hydropower-based Norwegian electricity grid are possible, and will be used for the first time on the Troll field with production start up planned for 1996. Diesel driven emergency power systems are installed on all manned installations.

Diesel fuel must be supplied from land while fuel gas supplies are taken directly from the gas produced by the platform.

SUPPORT AND SAFETY SYSTEMS

Production platforms are provided with all utility systems and functions to support the process and the platform operations. Safety systems are installed to meet the governmental safety regulations.

Support activities

Supply and Installation Services

Suppert activities are needed during all stages of production and transportation. These activities include passenger traffic, supply material, installations and services.

The consumable supplies range from personal goods as food and household articles to maintenance equipment. Drilling fluids and production chemicals are continuously being consumed. The supply vessels make regular trips to and from the operator’s onshore base. The operator normally contacts these vessels on a time charter basis. Supply vessels services are also available on the spot market.

Safety and Standby Vessels

To assist in case of unpredicted events such as blow-outs, platform accidents, man overboard accidents and other emergency situations, standby vessels are on service adjacent to the platform installation. In most emergency situations their assistance will be preliminary, rendering first aid, providing alternative communications and transportation possibilities. When additional help is required, ambulance helicopters and base-rescue take over. Every manned installation has a standby vessel in the immediate area.

Passenger Traffics and Helicopter Activities

Helicopter activities are divided into either onshore or offshore-based operations. The majority of the helicopters are based onshore and they transport personal to fixed and mobile offshore installations. Some helicopters are based offshore and these can be used for stand by service as well as internal traffic assignments and emergency search and rescue. There are permanent offshore-based helicopter bases at the Ekofisk, Statfjord and Frigg fields. The helicopters are also used for deliveries of urgent equipment or other special assignments.

Ship transport of personnel to the offshore facilities is not common practice in the Norwegian North Sea. Passenger transport to and from, offshore installations take place exclusively by helicopter.

TRANSPORTS OF CRUDE OIL AND NATURAL GAS

Transportation by Pipelines

There are a considerable number of oil and gas pipelines crisscrossing the North Sea bed. The pipelines can be categorised in two main groups.

1. oil and gas export pipelines going from the offshore fields to land -based receiving terminals.
2. infied pipelines transporting hydrocarbon fluids at various stages of processing between platforms and from sub sea installations to platforms.

Onshore pipelines are always buried while sub sea pipelines in many cases are left unburied. The large trunklines can resist heavy blows from trawler doors and other fishing gears and are generally only buried for short stretches in connection with landfalls. Pipelines are considered to have little impact on the local fishery since they are overtawlable.

Oil Shipment

Produced oil that is not being transported by pipelines is loaded from the platform installations via a loading buoy onto crude tankers. The majority of this is crude oil is unloaded at the Mongstad oil terminal in Western Norway, from where most of it is exported onward to markets in Europ and North America. The capability of the offshore loading crude tankers is about 100000 m3.

Offshore Loading Facilities
Previously offshore loading terminals were cylindrical steel tower with risers a rotating head, loading boom, a flexible transmission line and a helideck for standing equipment. A new type, which consists of a subsurface buoy with flexible risers/ transmission lines, is now installed on some fields. Flowlines convey production from the platform to the loading buoy over a distance of around 2 km. When a tanker arrives, the flexible transmission line is connected. The loading is then executed by pumping the oil from storage. The crude tankers are loading and unloading in a shuttle traffic manner. The total production is divided in production quotas according to the owner ship of the operating partnership companies. These companies may use different harbours usually within the North Sea Basin, and will have shipments delivered according to their production quotas.

System Boundaries

Nature Boundary	The environmental load taken account for are the substances emitted to air and sea, the resources used and the waste that is generated, when extracting and transporting the crude oil and gas. The following resource elements have been included: - Area, representing the surface area occupied by facilities or restricted for other use when the facility is in operation. - Energy, the energy is measured as the amount of fuel gas, diesel fuel and jet fuel consumed for power generation. Emissions to air cover the following: Combustion gases resulting from fuel gas, diesel and jet fuel based power and heat production, gas flaring, well test burning and incineration. Cold hydrocarbon vents and fugitive emissions. Escape of halon from five prevention systems. The emitted gases are comprised of CO_2, CO, NO_x, N_2O, CH_4, VOC, SO_2 and halon.The SO_2 emissions results from combustion of marine diesel fuel. The produced natural gas only contains traces of H_2S. AS a result the SO'' in the fuel gas exhaust is negligible. Small amounts of hydrocarbon gases are vented directly to the air from parts of the production processing line. There are several sources for these continuos and non-continuos emissions. stripping gas from glycol regeneration gas turbine start-up gas (on old platforms only) venting, purge and blanket operations fugitive emissions compressor system seal leakage The amount of gas venting is much lower on modern platforms than on the older ones. Emissions to water can be oil or other chemicals. The oil discharges can be either accidental spills or continuos planned discharges, such as oil dispersed in ballast water, discharged produced water and oil contained in discharged drilling fluids. The chemicals that are discharged are categorised in for different groups: - Drilling chemicals, which are discharged with the used drilling fluid. - Weighting materials, which is used in the drilling fluid to get sufficient fluid gravity. The weighting materials are discharged to sea with the drilling fluids. - Production chemicals, like corrosion inhibitors and biocides, are discharged with produced water, cooling water and dumped injection water. - Pipeline chemicals are corrosion inhibitors, methanol and glycol, which prevent hydrate formation in the pipelines. The chemicals are partly discharged to sea with the produced water.

Time Boundary	The development in gas and crude oil extraction is continuously progressing, and the data will therefore in time be out of date. The data are from 1991.
Geographical Boundary	Norway
Other Boundaries	The following waste is generated by the system The waste is classified in four different groups: - Hazardous waste, which is waste requiring special treatment, handling and disposal according to regulations - Household waste - Sewage - Industrial waste, which covers all the waste from production. Materials that are not recyclable are categorized as production waste. Not all the environmental load cased by the support activities are accounted for. Only emissions to air, material consumption and fuel consumption are summed up in the table. Things that are not accounted for are the drill strings used, chemical additives, food, supplies and the service of the supply base and home office. The construction of the equipment is not accounted for neither the energy consumption and emissions due to exploratory drilling.

Flow Data

General Activity QMetaData

Date Conceived	1994
Data Type	
Represents	Norwegian crude oil and gas
Method	The data are taken from Keiserås, Bakkane Kristin, Life cycle data for Norwegian oil and gas, 1994, Tapir publishers. Because the system, which the data represent, includes both the operation stage and the transportation stage, the values in the table are the sums of the values from table 6.2 and table 7.2 in Keiserås, Bakkane Kristin, Life cycle data for Norwegian oil and gas, 1994, Tapir publishers. All discharged to sea are based on aggregated data for the total Norwegian continental shelf. The data source for all oil discharges is the OLF Environmental Programme. Chemical discharge data are provided by the OLF. All emissions to air are estimated from aggregated data. Combustion gases are calculated by using standard emission factors for each emission gas. Data for fugitive emissions, consisting of CH4 and VOC are aggregated emission data from the total Norwegian continental shelf. The datasource is OLF environmental Programme Phase 2. Project C05: ''Direct Hydrocarbon Gas Emissions from Production and Riser Platforms'', Aker Engenering a.s. March 16th 1993.
Literature Reference	Keiserås Bakkene Kristin, Life cycle data for Norwegian oil and gas, 1994

	Output	Product	Crude oil	786000			tonne	Technosphere	
	Output	Product	Gas	213000			tonne	Technosphere	
Method: Aggregated data for the total Norwegian oil and gas industry have been obtained from the waste receiving company Notes: Hazardous waste, is waste requiring special treatment, handling and disposal according to regulations	Output	Residue	Hazardous waste	315			tonne	Other	
Method: The household waste has been calculated using aggregated data from Statoil and scaled up.	Output	Residue	Household waste	265			tonne	Other	
Method: Industrial waste delivered to the onshore receiving plant. Data from Statoil are used and scaled up according to gas and oil production volume to cover the total industry. Scrap material on the sea floor collected through sea bottom surveys by NPD in 1992. Amounts for 1991 is assumed to equal quantities collected in 1992. Non -recycled parts of the facilities are recorded as industrial waste at the demobilisation stage, which is not part of this system. Notes: Industrial waste, covers all the waste from production. Materials that are not recycable are categorised as production waste.	Output	Residue	Industrial waste	74			tonne	Other	
Method: The total quantities of sewage are based on average per capita factors and split 25%on exploration and 75% on the production stage. Only the latter beeing part of this system.	Output	Residue	Sewage	6741			m3	Other	

About Inventory	
Publication	Keiserås, Bakkane Kristin, Life cycle data for Norwegian oil and gas, 1994, Tapir Publishers -- Data documented by: Sara Ågren, project employed at Technical Environmental Planning, Chalmers University of Technology Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	
General Purpose	
Detailed Purpose	An attempt to clarify and assemble, unquantified and widely scattered information regarding Norwegian petrolium activities.
Commissioner	- .
Practitioner	Keiserås, Bakkane Kristin - Novatech a.s. P.O. Box 163 N-4033 Forus Norway.
Reviewer	
Applicability	The data are specific for offshore, by Norwegian standards extracted, crude oil and can therefore not with succsess be used for other countries oil production. Extraction of oil in Norway is internationally considered to be one of the most environmental

	friendly, because the oil companies have to follow strict environmental laws and therefore use the most advanced technology and equipment available on the market.
About Data	The data set includes all sites producing oil and natural gas in Norway.

About Inventory

Publication	Davis J, Haglund C (1999). ''Life Cycle Inventory (LCI) of Fertiliser Production - Fertiliser Products Used in Sweden and Western Europe''. SIK report no. 654. The Swedish Institute for Food and Biotechnology (SIK). Gothenburg, Sweden. -- Data documented by: Jennifer Davis, SIK (The Swedish Institute for Food and Biotechnology). Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The data are intended to be us
General Purpose	To generate an inventory of emissions and use of resources for the production of fertilisers used in Sweden.
Detailed Purpose	The purpose was not to compare the production of different fertilisers with each other but to generate a thorough inventory of emissions and use of resources for the production of fertilisers used in Sweden. Extraction of dolomite in Norway is one step in the line of production of the fertilisers manufactured at Hydro Agri AB in Landskrona, Sweden. The data

	are intended to constitute a useful basis of input information in life cycle assessments of food production systems.
Commissioner	- SIK AB, The Swedish Institute for Food and Biotechnology Box 5401 SE-402 29 Gothenburg Sweden .

SPINE LCI dataset: Extraction of sulphur and production of sulphuric acid

Administrative

Finished	Y
Date Completed	99-01-25
Copyright	
Availability	Public

Technical System

Name	Extraction of sulphur and production of sulphuric acid
Functional Unit	1 kg of sulphuric acid (100 %)

Functional Unit Explanation	
Process Type	Other
Site	
Sector	Materials and components
Owner	
Technical system description	This dataset is intended to represent average values for production of sulphuric acid used in production of fertilisers used in Western Europe. Data have been taken from literature, no specific site has been studied. It has been assumed that 50 % of the sulphur used for production of sulphuric acid in the EU originates from the desulphurization of crude oil or natural gas, 30 % comes from other sulphides than pyrite and 20 % is derived from regeneration of waste acid. Further information on the method used to generate this dataset is given under ''method''. It is uncertain what exact techniques for production of sulphuric acid the data taken from literature represent. The text below gives generic information about extraction of sulphur and production of sulphuric acid. Sulphur is unusual compared to other minerals in that it is mainly used as a chemical reagent rather than as a component of a finished product. Sulphuric acid is the most common sulphur containing intermediate product and world-wide, well over half of the sulphuric acid is used in the manufacture of phosphorus and ammonium sulphate containing fertilisers (Kirk-Othmer, vol. 23, 1997). The most common sulphur sources are elemental sulphur from natural deposits (brimstone) and from desulphurization of natural gas or crude oil, sulphur dioxide from roasting of pyrites (FeS) and other metal sulphides, spent (contaminated or diluted) sulphuric acid, metal sulphate roasting and combustion of sulphur containing gases, such as hydrogen sulphide (H2S), carbon disulphide (CS2) and carbon sulphoxide (COS) (Kirk-Othmer, vol. 23, 1997; BAT N° 3, 1995). Elemental sulphur is by far the most widely used raw material for production of sulphuric acid (Kirk-Othmer, vol. 23, 1997). Extraction of Elemental Sulphur from Natural Deposits Ores containing native sulphur are found exclusively in the upper layer of the Earth's crust and are either of sedimentary origin or volcanic origin. Sulphur ores can be extracted either by normal open-pit or underground mining methods depending on the geology of the deposit. Under special geological conditions elemental sulphur is produced directly by fusion of hot water (Frasch process) (Ullmann, vol. A 25, 1994). The Frasch Process In some places where the geological structure is sedimentary, intrusion of rock salts from lower levels has distorted an overlying layer of anhydrite (calcium sulphate), dolomite (calcium-magnesium carbonate) and limestone (calcium carbonate) into dome-like structures. The anhydrite and the clays that lie over the limestone are impervious and the theory is that oil once accumulated in the more porous layer of limestone and dolomite. It is then thought that bacteria reduced the sulphate from the anhydrite to elementar sulphur and these bacteria are also thought to be responsible for the disappearance of oil in these accumulations. As a result the elemental sulphur is dispersed through the dolomite and limestone layers of the rock and the sulphur content varies from a few percent to 50 % (Ullmann, vol. A 25, 1994). The Frasch process involves injecting large quantities of hot water directly into the deposit, and thereafter pumping molten sulphur up to the surface. A well is drilled through the sulphur bearing layers down to the top of the underlying, impermeable anhydrite layer. Three coaxial pipes with different diameters are introduced into the borehole and pressurised water (2.5-3 MPa) at 165°C is forced down the annular space between the outer and the middle pipe. The water passes through perforations at the lower end of the outer pipe, since there is a collar that closes off the space between the two pipes about halfway down the perforations. The hot water penetrates into the cracks, pores and larger voids of the sulphur-bearing limestone, which results in melting of the sulphur. Since the density of sulphur is higher than the density of water, the sulphur collects at the bottom of the borehole. When a reservoir of molten sulphur has been established there, the water is turned off and the sulphur flows through the bottom openings, below the collar, of the outer pipe into the middle pipe. As sulphur has about 1.8 the density of water, it will only rise about halfway up the middle pipe under the influence of hydrostatic pressure. Hot compressed air is then injected through the innermost pipe. The resulting foam of sulphur and air is very light and rises easily the remaining distance to the surface. The sulphur is then transferred to a heated storage tank or solidified as slates, prills, pellets or pastilles. The extracted sulphur can be quite pure, 99.7-99.8 %, and light yellow in colour, but if it is contaminated by even small amounts of bituminous residues from the oil, it is brown or occasionally blackish in appearance. It is complicated to remove these impurities from the sulphur, but anyhow, the dark sulphur is acceptable for many uses (Ullmann, vol. A 25, 1994). Even though the Frasch process was originally developed to take advantage of the sulphur deposits in the area around the Gulf of Mexico, the technique has been further developed for use on less ideally structured deposits in Poland and Iraq (Ullmann, vol. A 25, 1994). The cost of energy is the greatest problem facing the Frasch process today. The required amount of hot water, which depends on the geological conditions at the bottom of the borehole, is the most important factor. Approximately 3-38 m3 of water at 165°C is required to produce one tonne of sulphur. In the aim of saving energy the Frasch process

could be combined with production of electricity which can be sold locally. Another possibility to save energy is the reuse of the hot injection water, but the problem is contamination of this water with, for example, hydrogen sulphide (Ullmann, vol. A 25, 1994).

Conventional Mining

All deposits, especially sedimentary ones, are not suitable for mining by Frasch techniques. In these cases conventional mining and benificiation techniques are utilised. Mining methods that have been practised include both surface open pit mining and subsurface tunnelling, room and pillar, cut and fill and various stoping systems (some of these mining methods are described in 10.4 potash salt). The choice of mining method is determined by the size, shape and depth of the ore deposit. High grade sulphur ores have often been roasted directly, but medium and low-grade sulphur ores have been beneficiated by the application of different techniques for sulphur recovery, such as flotation, melting, distillation, agglomeration and solvent extraction (Encyclopedia of Chemical Processing and Design, vol. 55, 1996).

Conventional mining and processing operations are normally more costly than Frasch operations for sulphur exploitation and are therefore normally employed only where political protection or other special local market conditions apply. Because of this Russia, Poland and China are the only countries that produce sulphur by conventional mining methods to a large extent today and this corresponds to 8 % of the global sulphur production (Encyclopedia of Chemical Processing and Design, vol. 55, 1996).

Desulphurization of Crude Oil and Natural Gas

Petroleum contains a variety of organic sulphur compounds, such as for example thiols, alkyl and aryl sulphides, thiophenes and more complex aromatic sulphur compounds. When crude oil is distilled at the refinery, the sulphur is partitioned between the various product fractions. Most of the sulphur is found in the heaviest fractions and in the residues. These were formerly used as industrial fuel, but since this contributed to atmospheric sulphur dioxide pollution, most industrial countries have now introduced regulations which limit the use of sulphur containing oil fractions as fuel. Therefore fuel oil has to be desulphurized at the refinery nowadays (Ullmann, vol. A 25, 1994).

Desulphurization of oil products can be achieved by reacting the sulphur components in the oil with hydrogen over a catalyst. The required pressure and temperature is dependent on the kind of oil that is desulphurized, e.g. heavy oil fractions require higher pressure than light oil fractions (Scanraff miljörapport, 1997). The resulting gas mixture is then pressurised, fed into an absorption tower and hydrogen sulphide is washed out by a circulating solution, e.g. amine, potassium carbonate, ether or glycol solution, in which it is either physically or chemically absorbed. Thereafter the solution is subjected to heat and depressurised and hydrogen sulphide is separated from the solution as the top product in a stripping tower. In the chemical solvent process the solution has to be stripped with steam, while in the physical solvent process much of the dissolved hydrogen sulphide comes out of the solution when the liquor is depressurised, i.e. less energy is required (Ullmann, vol. A 25, 1994).

Natural gas contains sulphur, mainly as hydrogen sulphide, and the proportions of sulphur vary widely. Some natural gas deposits contain no sulphur at all while the sulphur content can reach 30 % in others. Hydrogen sulphide must be removed before the natural gas is piped due to its toxicity. Therefore the gas must be processed at the wellhead. In such case, the separation of hydrogen sulphide is achieved in the same way as described above (Ullmann, vol. A 25, 1994).

Once it has been separated from other useful constituents of the gas mixture, hydrogen sulphide is normally converted into a more useful form of sulphur, e.g. elemental sulphur and sulphuric acid, since hydrogen sulphide is a very dangerous gas which has few industrial uses. The product choice is often elemental sulphur, which is cheaper and easier to transport than sulphuric acid (Ullmann, vol. A 25, 1994). The hydrogen sulphide gas is transferred to the sulphur recovery plant, often referred to as the Claus plant, which is divided into a combustion part and a reactor part. In the first part the hydrogen sulphide is partially combusted and elemental sulphur and sulphur dioxide are formed. The elemental sulphur is condensed and separated and the gas mixture of sulphur dioxide and hydrogen sulphide is led to the reactor part, which can consist of a various amount of reactors. The catalyst in the reactors is, for example, aluminium oxide and the formed elemental sulphur is condensed after each reactor (Ullmann, vol. A 25, 1994; Scanraff miljörapport, 1997). The concentration of sulphur dioxide and hydrogen sulphide in tail gas can be controlled by addition of air to the sulphur recovery plant. The recovery ratio of sulphur can be more than 99 % if the remaining sulphur dioxide in the tail gas is converted to hydrogen sulphide in an additional tail gas plant and the hydrogen sulphide thereafter is absorbed by a solution which is led back to the sulphur recovery plant (Scanraff miljörapport, 1997).

Extraction of Pyrite

The main deposits of pyrites are located in Spain and Portugal, but pyrite is also mined in Norway, Cyprus, Germany, Northern Italy and Russia (Ullmann, vol. A 25, 1994). In the absence of any elemental sulphur resources within the country, the use of pyrites as source of sulphur attains utmost importance. The main pyrite ore occurs in three distinct types, crystalline pyrite, shaly pyrite and amorphous pyrite (Prasad et al., 1994).

Production of sulphuric acid

Sulphuric acid results from the production of sulphur dioxide, its conversion into sulphur trioxide and finally, absorption of sulphur trioxide by water, giving sulphuric acid. These reactions are exothermic to various extent, except for the production of sulphur dioxide from metal sulphate roasting or regeneration of sulphuric acid, and, in the case of brimstone as raw material, 1.1 to 1.2 t steam is produced per tonne sulphuric acid. This steam can, for example, be used to produce electricity and to concentrate phosphoric acid in adjacent plants. Since there are many different sulphur raw materials, there are several ways of producing sulphur dioxide as well (UNEP, 1996). Thereafter, the production route is less dependent on the original sulphur source, even though there are several processes for the conversion and the absorption stage (BAT N° 3, 1995). Approximately 0.33 t brimstone, 0.76 t pyrite (48 % S) or 1.2t zinc ore is typical raw material input for the production of 1t sulphuric acid (100%) (UNEP, 1996).

Production of Sulphur Dioxide

Combustion of Sulphur
The elemental sulphur is first melted by heating to 135°C and the combustion is then carried out in a combustion unit at temperatures ranging from 900°C to 1800°C. The combustion unit consists of a combustion chamber followed by process gas cooler, since the reaction is strongly exothermic. The combustion gases are often diluted from around 18 % to 9 - 12 % sulphur dioxide by volume before entering the conversion process (BAT N° 3, 1995).

Roasting of Pyrite
Pyrite, or iron sulphide, is roasted in various types of furnaces, e.g. multiple-hearth furnace, rotary kiln and fluid bed roaster, producing a gas with a somewhat lower sulphur dioxide content than the combustion gases from burning elemental sulphur. This gas is then diluted to 8-10 % sulphur dioxide and treated in a high efficiency dust collector, e.g. electro-static dust collector, before conversion (BAT N° 3, 1995). The sulphur oxides is the main product and the iron oxides is the by-product (Patyk, 1996).

Other Metal Sulphide Roasting
Ores containing zinc, copper and lead sulphides are similarly roasted as iron sulphide in metallurgical processes, usually producing gases with even lower sulphur dioxide content (BAT N° 3, 1995). Here, the sulphur dioxide is a by-product and the metals are main products (Patyk, 1996).

Metal Sulphate Roasting
Metal sulphates, e.g. ferrous sulphates can be roasted, similarly as pyrite, using elemental sulphur and pyrites, but also coke, tar, lignite, coal and oil as both fuel and reductant. The content of sulphur dioxide in the combustion gases varies but is normally around 6-7 %. Large quantities of ferrous sulphate is obtained as the heptahydrate form (FeSO4*7H2O), during regeneration of pickling liquors or as a by-product in the titanium oxide process using the sulphate route. The heptahydrate is first dehydrated and the decomposed in a second stage (BAT N° 3, 1995).

Sulphuric Acid Regeneration
Regeneration of sulphuric acid is achieved by decomposition in a hot gas stream or a moving beds of solids, e.g. coke, sand or ore, at 800-1300°C. The produced gas contains 2-10 % sulphur dioxide, depending on the quality of spent acid. To compensate for quality, a complementary sulphur burner can be used to provide supplementary sulphur dioxide. The energy demand also vary with the quality of spent acid, rising steeply as acid concentration decreases and level of organic impurities increases and therefore a preceding concentration by evaporation to 60-75 % sulphuric acid often is energetically more favourable. The sulphur dioxide content is heavily diluted by the combustion gases and when using fuel oil, the acid concentration must be at least 60 % to obtain sufficient sulphur dioxide content for further processing in a double-contact sulphuric acid plant (BAT N° 3, 1995).

Combustion of Sulphur Containing Gases
The combustion of hydrogen sulphide (H2S), carbon sulphoxide (COS) and carbon disulphide (CS2) is carried out in a muffle furnace at 800-1200°C. The content of sulphur dioxide in the combustion gases is variable, between 0.5-12 % and depends on the raw material and processes used (BAT N° 3, 1995).

Production of Sulphur Trioxide
A catalyst, often containing alkali and vanadium oxides, is involved in the conversion of sulphur dioxide into sulphur trioxide (BAT N° 3, 1995). In case of roasting of metallic sulphides the sulphur dioxide containing combustion gases are first cleaned and dried, but if the sulphur dioxide is produced via sulphur burning, the air is dried before combustion (UNEP, 1996). If the oxygen concentration in the process gas is low after the combustion or roasting step, additional air or oxygen must be added prior to or during catalytic oxidation to ensure that there is an excess over stoichiometric needs for conversion of sulphur dioxide to sulphur trioxide. This reaction is highly exothermic and equilibrium becomes increasingly unfavourable for sulphur trioxide formation as temperature increases above 410-430°C. Unfortunately, this is the minimum temperature level required for typical commercial catalysts to function. As a result, plant catalytic converters are typically designed as multistage adiabatic units with gas cooling between each stage (Kirk-Othmer, vol. A 23, 1997).

Production of Sulphuric Acid

Single Contact Process
In single contact plants, sulphuric trioxide is absorbed at the end of the process. Nowadays, this process is only used in new plants when the sulphur dioxide content of the combustion gas is low and widely varying (UNEP, 1996). After the conversion step the sulphur trioxide is absorbed in sulphuric acid in absorbers where it is converted to sulphuric acid by the water in the sulphuric acid. The absorbing acid is kept at the constant desired concentration of

approximately 99 % by the addition of water or dilute sulphuric acid. If the concentration of sulphur dioxide in the combustion gas is between 6 and 10 %, the conversion efficiency is about 98 %. It is difficult to obtain more than 98.0 % in existing plants. The conversion ratio is somewhat lower if the concentration of sulphur dioxide in the combustion gas is less then 6 % (BAT N° 3, 1995).

Double Contact Process
In the early 1970s, air pollution problems led to the adoption of the double contact process or double absorption process (Kirk-Othmer, vol. 23). In this process there is a primary converter followed by an intermediate absorber, a secondary converter and a final absorber. The absorption of sulphur trioxide in the intermediate absorber shifts the equilibrium towards the formation of sulphur trioxide in the residual gas, resulting in an overall conversion efficiency of at least 99.6 % in case of sulphur burning. Feed gases containing 9-12 % sulphur dioxide is generally used for this process (BAT N° 3, 1995).

Pressure Contact Process
The oxidation of sulphur dioxide is favoured by high pressure and therefore, pressure contact processes has been developed. In these processes the sulphur dioxide conversion and the sulphur trioxide absorption are both carried out at high pressure. Even higher conversion ratio, 99.80-99.85 % is reported for this type of process. On the other hand, the temperature in the sulphur furnace is higher than the double contact process, which increases the nitrogen oxide formation. The process also consumes more power and produces less steam than the conventional double-contact process. The process is not new but so far, it has only been employed in one industrial double-absorption plant in France (BAT N° 3, 1995).

Wet Contact Process
Contrarily to the conventional contact processes in which dry mixtures of sulphur dioxide and air are treated, wet gas is used in the wet gas process. This process has been employed to treat off-gases containing at least 10% hydrogen sulphide from cookeries, mineral oil refineries, fuel gasification or low-temperature carbonisation plants, natural gas cleaning installations, carbon bisulphide production plants and synthetic fibre plants. The hydrogen sulphide in the treated off-gas is first burnt to sulphur dioxide and water (steam) and the sulphur dioxide is then converted to sulphur trioxide which together with the formed steam yields sulphuric acid. The concentration of the produced acid is between 78 and 93 %. Gases with a lower hydrogen sulphide content than 10% have to be burnt by additional heating, e.g. fuel gas, oil or sulphur (UNEP, 1996). The conversion efficiency, regarding sulphur dioxide, of the Wet Contact Process is normally about 95-98 % (BAT N° 3, 1995).

Other Processes
The Modified Lead Chamber process is able to treat gases with a low content of sulphur dioxide, 0.5-8 %, but also gases containing a mixture of sulphur dioxide and nitrogen oxides. The nitrogen oxides are used to promote acid production directly from sulphur dioxide. The process is potentially useful for cleaning the off-gases from power plants and ore roasting plants. The conversion efficiency is almost 100% for sulphur dioxide contents between 0.5 and 8 % but emissions of nitrogen oxides occur to relatively high extent (BAT N° 3, 1995).

There is also a process in which hydrogen peroxide is used to convert sulphur dioxide to sulphur trioxide. The efficiency is higher than 99 % and no waste is generated but the cost for hydrogen peroxide makes this process uneconomic for sulphuric acid production, unless emissions lower than those of the double contact process are required (BAT N° 3, 1995).

The most recent and rather radical development in sulphuric acid technology has taken place in Russia. A process in which the gas flow is periodically reversed over a single-bed converter has been reported. It is claimed that this process permits the treatment of gases of low and variable concentrations of sulphur dioxide, without the need for much of the expensive heat exchange equipment associated with other processes (BAT N° 3, 1995).

System Boundaries

Nature Boundary	The system starts with extraction of sulphur and ends with sulphuric acid leaving the factory gate. Emissions from production of steam are not included. Emissions and consumption of energy and resources due to the production and disposal of catalysts used in the sulphuric acid process are not included. However, this is assumed to be of minor importance since the catalyst material often is recycled to a large extent.
Time Boundary	The literature from which data are taken from is published in 1996 and 1998.
Geographical Boundary	Europe.
Other Boundaries	
Allocations	Not applicable.
Systems Expansions	Not applicable.

Flow Data

General Activity QMetaData

Date Conceived	
Data Type	Derived, unspecified
Represents	As no data for extraction of dolomite in Norway was obtained, figures from Swedish extraction of dolomite has been used.
Method	According to Patyk (1996) 50 % of the sulphur used for production of sulphuric acid in the EU originates from the desulphurization of crude oil or natural gas, 30 % comes from other sulphides than pyrite and 20 % is derived from regeneration of waste acid. Elemental sulphur from desulphurization of crude oil or natural gas is not linked to any energy consumption since the sulphur here is regarded as a by-product, but the net export of energy in form of steam from the production of sulphuric acid is around 3.6 GJ/t H2SO4. The net export of steam from the production of sulphuric acid from sulphides is approximately 0.98 GJ/t H2SO4 and production of sulphuric acid using waste acid as raw material consumes about 5 GJ steam/t H2SO4 (Patyk, 1996). This leads to a balancing value for consumption of steam of -1.1 GJ/t H2SO4, which implies a net export of steam. This value has been assessed to be relevant as an average value for the production of sulphuric aid used in Western Europe, when taking data from Kongshaug (1998) into account. Concerning emissions of sulphur dioxide (SO2) and sulphur trioxide (SO3), the figures 5 kg SO2/t H2SO4 and 0.3 kg SO3/t H2SO4 have been chosen as representative values for production of sulphuric acid used in Western Europe. See also ''specific QMetaData''. Emissions and consumption of energy and resources due to the production and disposal of catalysts used in the sulphuric acid process are not included. However, this is assumed to be of minor importance since the catalyst material often is recycled to a large extent.

About Inventory	
Publication	Davis J, Haglund C (1999). ''Life Cycle Inventory (LCI) of Fertiliser Production - Fertiliser Products Used in Sweden and Western Europe''. SIK report no. 654. The Swedish Institute for Food and Biotechnology (SIK). Gothenburg, Sweden. -- Data documented by: Jennifer Davis, SIK (The Swedish Institute for Food and Biotechnology). Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology --
Intended User	The data are intended to be us
General Purpose	To generate an inventory of emissions and use of resources for the production of fertilisers used in Sweden and Western Europe.
Detailed Purpose	The purpose was not to compare production of different fertilisers with each other but to generate a thorough inventory of emissions and use of resources due to the production of fertilisers used in Sweden and Western Europe. The data are intended to constitute a useful basis of input information in life cycle assessments of food production systems. Production of sulphuric acid is one step in the line of production of fertilisers containing phosphorus.
Commissioner	- SIK AB, The Swedish Institute for Food and Biotechnology Box 5401 SE-402 29 Gothenburg Sweden .
Practitioner	Davis, Jennifer and Caroline Haglund - SIK AB Box 5401 402 29 Gothenburg Sweden.
Reviewer	-
Applicability	The data are intended to be used as input information for the production of phosphoric acid that is used in production of fertilisers used in Western Europe. The dataset is included in aggregated datasets for production of fertilisers containing phosphorus used in Western Europe (cardle to gate).
About Data	The only emissions taken into account are emissions of SO2 and SO3 due to lack of information. All data are taken from literature, no specific site has been studied.
Notes	Internal review of the report was performed by: Olle Ramnäs, CTH (Chalmers University of Technology), Berit Mattsson and Magnus Stadig, SIK (The Swedsih Institute for Food and Biotechnology).

SPINE LCI dataset: Extraction to ABS APME

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Extraction to ABS APME
Functional Unit	1 kg of ABS (acrylonitrile-butadiene-styrene copolymer)
Functional Unit Explanation	According to the schematic flow diagram in the ''Eco-profiles...'' report, the product is a mixture (weighted average?) of mass polymerised ABS copolymer and compounded ABS copolymer. ABS is a two-phase polymer consisting of a glassy matrix of a copolymer of styrene (C6H5-

	CH=CH2) and acrylonitrile (CH2=CH-CN), and the synthetic rubber copolymer of styrene and butadiene (CH2=CH-CH=CH2). The glassy and rubbery phases are grafted in a suitable way. ABS copolymers are engineering polymers with good toughness, temperature stability and solvent resistance properties. They can be formed using all of the common plastics techniques and can also be cold formed using techniques associated with metals. Typical uses of ABS: interior and exterior automotive parts, housings for domestic appliances such as hair driers and vacuum cleaners, kitchen appliances such as refrigerator linings and mixing machines, furniture parts, telephones, toys, pipes and profiles.
Process Type	Cradle to gate
Site	European average values, Used for identification of owner and/or site in Object of study under Technical system for activity
Sector	Materials and components
Owner	European average values, Used for identification of owner and/or site in Object of study under Technical system for activity
Technical system description	Production of ABS (acrylonitrile-butadiene-styrene copolymer) including all major operations from extraction of crude oil and gas to polymerisation and compounding. According to a schematic flow diagram in the ''Eco-profiles...'' report, the following sub-processes are included: - Cracking of naphtha and/or natural gas for ethylene, propylene and butenes. - Styrene production: Reforming of naphtha for benzene + production of benzene from cracking products (''pygas'') in an aromatics plant, ethylene from cracker, ethylbenzene production, styrene production. - Acrylonitrile production: Propylene from cracker, production of ammonia from natural gas and air, production of acrylonitrile from ammonia and propylene. - Polybutadiene production: Butenes + butadiene from cracker, dehydrogenation of butenes to butadiene, polymerisation of butadiene. - ABS mass polymerisation. - ABS graft copolymer production. - ABS polymerisation. - Compounding. In addition to the mentioned sub-processes, the following major processes are included: Crude oil extraction and delivery; oil refining for naphtha (fractional distillation); natural gas extraction, processing and delivery; coal mining and delivery. Also electricity production and production of other raw materials have been included on a cradle to gate basis, i.e. all materials and energies have been traced back to the extraction of raw materials from the earth. Operating conditions: As the data are based on information from 5 plants in 3 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. Some more information about the processes are found in the ''Eco-profiles...'' reports for ABS (acrylonitrile-butadiene-styrene copolymer), naphtha and the other intermediates, and the Methodology report, which are available at APME''s web site http://lca.apme.org.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available.'' Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under their specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment. Emissions <0.5 mg were presented as <1 mg in the Eco-profiles result tables. In this activity, however, they are presented as 0.25 mg (1/2 of the maximum value 0.5 mg). Note that the actual values may be far below 0.5 mg in some cases. The energy resources Hydrogen and Sulphur have been excluded by GM, since these parameters do not represent true natural resources, but are reported as primary energy equivalents for energy balancing purposes. Probably they are included in other resources, e.g. crude oil and gas. Nuclear energy has been recalculated to natural uranium resource. Only Hydro energy and Unspecified energy are kept as primary energy equivalents in the flow table.
Time Boundary	Data refer to the year 1995. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Results are based on data for 5 ABS production plants that produced 360 000 tonnes (unknown fraction of the total European production). Data were supplied by 5 plants in 3 countries: Germany, Italy and Netherlands. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates. For the intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides that plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included.) - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most other cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0.01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Methodology report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g., sulphuric acid is used as a drying agent for chlorine; therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of

	chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity.
Systems Expansions	Not applied. The amount of Recovered energy is reported as a negative primary energy equivalent input.

Date Conceived	1995
Data Type	Derived, mixed
Represents	As no data for extraction of dolomite in Norway was obtained, figures from Swedish extraction of dolomite has been used.
Method	European average data. Results are based on data supplied by 5 ABS production plants in 3 countries: Germany, Italy and Netherlands. Their total production was 360 000 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45.0 MJ/kg for crude oil, 38.8 MJ/m3 (54.1 MJ/kg) for natural gas, 28.0 MJ/kg for coal, 15.0 MJ/kg for lignite, 9.3 MJ/kg for sulphur. Emissions and resources <0.5 mg have been assumed by Gunnar Mattson, ABB Corporate Research (GM) to be 0.25 mg, i.e. half the ''<'' values given, which is in accordance with common statistical procedure. The energy resources Hydrogen (0.10 MJ) and Sulphur (0.06 MJ) have been excluded by GM, since these parameters do not represent true natural resources, but are reported as primary energy equivalents for energy balancing purposes. Probably they are included in other resources, e.g. crude oil and gas. Nuclear energy has been recalculated to natural uranium resource. Only Hydro energy and Unspecified energy are kept as primary energy equivalents in the flow table.
Literature Reference	''Eco-profiles of the European plastics industry'', report for ABS (acrylonitrile-butadiene-styrene copolymer), naphtha and the other intermediates. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. (APME = Association of Plastics Manufacturers in Europe)
Notes	In the result tables in the ''Eco-profiles...'' report, not only total fuels and feedstocks, emissions to air and water, and solid waste are presented, but also the amounts caused by fuel production, fuel use, transport, feedstock (only for fuels and feedstocks) and processes. As the APME substance nomenclature and the ABB database nomenclature sometimes differ, the original APME substance name is given within '''' in the flow metadata Notes field. Please note: Some other interpretations/changes have been made from the original report by Gunnar Mattson, ABB Corporate Research. See Method and AboutData for details.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', reports for ABS (acrylonitrile-butadiene-styrene copolymer), naphtha and the other intermediates. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. (APME = Association of Plastics Manufacturers in Europe) The APME project co-ordinator: Vince Matthews. The members of the original independent expert panel: Ian Boustead, Paul Fink, Horst Langowski, Gustav Sundstrom. --- Editor: Data were entered into the SPINE format by Gunnar Mattsson, ABB Corporate Research, 2001-06-18. Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 29 October 2001 ---
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as building blocks for use in the construction of complete life cycle analyses. 1) Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2) Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies. - Internal company benchmarking. - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occurred since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	- APME, Association of Plastics Manufacturers in Europe Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels .
Practitioner	Boustead, Ian - .
Reviewer	
Applicability	The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for ABS production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data on the ABS production processes have been supplied by 5 plants in 3 European countries. Data are probably fairly representative for production of ABS in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature.

	The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Note that emissions <0.5 mg (0.25 mg in data table) may be far below 0.5 mg in some cases. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, data for each production sequence (i.e. each plant + its specific suppliers) are calculated separately. The final result is the average of the results from the individual production sequences weighted by the output from each sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45.0 MJ/kg for crude oil, 38.8 MJ/m3 (54.1 MJ/kg) for natural gas, 28.0 MJ/kg for coal, 15.0 MJ/kg for lignite, 9.3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO_2 emission. CO_2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO_2 emission (kg/MJ fuel) = 3.67 x {mass fraction of carbon in fuel}/{calorific value of fuel}. The following interpretations/changes from the original report have been made by Gunnar Mattson, ABB Corporate Research: - Nuclear energy has been recalculated to natural uranium resource. - Ferromanganese, Phosphate and Rutile have been recalculated to the corresponding amounts of Mn, P and Ti resources. - The energy resources Hydrogen and Sulphur have been excluded, as these parameters do not represent true natural resources. - Emissions and resources <0.5 mg (<1 mg in the Eco-profiles result tables) are presented as 0.25 mg, i.e. 1/2 of the ''<'' value. This is in accordance with common statistical procedure.
Notes	--- --- Changes made to the data set after publishing in SPINE@CPM--- >>> 29 October 2001 <<< Changes made by Gunnar Mattson, ABB Corporate Research: The general documentation of the data have been supplemented to improve the transparency and the consistency with other published data sets from the APME reports. The earlier published edition of the data set were named ''Production of ABS co-polymer granules'', and were documented by Sofia Medin, Electrolux Research and Innovation AB.

SPINE LCI dataset: Extraction to polycarbonate APME

Technical System	
Name	Extraction to polycarbonate APME
Functional Unit	1 kg of polycarbonate
Functional Unit Explanation	Polycarbonate compound. Polycarbonate is a transparent, crystalline thermoplastic engineering polymer. Typical applications are: housings for domestic appliances; office equipment; electrical systems, switches and housings; compact discs and optical storage; medical devices; food containers and packaging; glazing and lightning applications; safety glasses.

Process Type	Cradle to gate
Site	European average values, Used for identification of owner and/or site in Object of study under Technical system for activity
Sector	Materials and components
Owner	European average values, Used for identification of owner and/or site in Object of study under Technical system for activity
Technical system description	Production of polycarbonate including all major operations from extraction of raw materials to polycarbonate compounding. The repeating unit in polycarbonate is -O-C6H6-C(CH3)2-C6H6-O-CO-. Polycarbonate is commonly produced by the reaction of phosgene with bisphenol A. Phosgene is produced by reacting chlorine from the electrolysis of sodium chloride with carbon monoxide produced by pyrolysis of coal, oil or gas. Usually, phosgene is manufactured on-site. Bisphenol A is produced by reacting phenol and acetone. Acetone is produced from cumene, which is produced by reacting benzene and propylene. Phenol is obtained as a co-product from acetone production from cumene, but also by oxidation of toluene. Some of the benzene and all of the toluene are produced by hydrogenating (reforming) the naphthenic compounds in naphtha. By cracking of naphtha or natural gas, propylene, hydrogen, some benzene and other by-products are produced. In addition to the mentioned sub-processes, the following major processes are included: Crude oil extraction and delivery; oil refining for naphtha; natural gas extraction, processing and delivery; coal mining and delivery; coke production; sodium chloride extraction and purification. Also electricity production and production of other raw materials have been included on a cradle to gate basis, i e all materials and energies have been traced back to the extraction of raw materials from the earth. Operating conditions: As the data are based on information from a number of plants in different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. Some more information about the processes are found in the ''Eco-profiles...'' report 13; for example, see process flowchart in Figure 3.

System Boundaries	
Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available.'' Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since parameters that are not monitored by the companies have been estimated. The categories used to identify the different emissions or groups of emissions are empirical. For instance, methane and aromatic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under their specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Emissions <0,5 mg are presented as <1 mg in the result tables. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment.
Time Boundary	The participating companies and suppliers of major raw materials were requested to supply data for a 12 month period during 1992-94. Data for other upstream production of fuels and raw materials are probably from the same time, or somewhat older. For some of the intermediates, data published in the ''Eco-profiles...'' reports 2, 3 (1993) and 4 (1997) have been used, although additional information has been added.
Geographical Boundary	European average data. Results are based on data for polycarbonate production plants that produced 170.000 tonnes/year. Data were supplied by the 3 producers in Europe operating in Germany and the Netherlands, and are believed to be representative of the total European production of 400.000 tonnes/year.
Other Boundaries	No excluded subsystems are mentioned. No cut-off criteria for exclusion of minor inputs and outputs are stated.
Allocations	It is stated that ''those inputs and outputs, which could not be subject to stoichiometric allocation, have to be partitioned using an alternative method - usually using mass''. Stoichiometric allocation was probably applied to the electrolysis of sodium chloride. In the ''Eco-profiles...'' report 2, the following allocations were mentioned: Inputs and outputs to/from the North Sea oil rigs have been partitioned between the different products on the basis of the calorific values of the products. Inputs and outputs to/from the refineries have been partitioned across all usable or saleable refinery products on the basis of mass. This also applies to the products from the crackers.

Flow Data

General Activity QMetaData

Date Conceived	1992-94
Data Type	Derived, mixed
Represents	As no data for extraction of dolomite in Norway was obtained, figures from Swedish extraction of dolomite has been used.
Method	European average data. Results are based on data for polycarbonate production plants that produced 170.000 tonnes/year. Data were supplied by the 3 producers in Europe and are believed to be representative of the total European production of 400.000 tonnes/year. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production line (i e each polymerisation plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production lines weighted by the output from each production line (polymerisation plant). Horizontal averaging has, however, been applied for some processes over which the polycarbonate producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. Probably, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and energy, the following gross calorific values (energy content) have been used in the calculations: 45,0 MJ/kg for oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur.
Literature Reference	''Eco-profiles of the European plastics industry'' Report 13: Polycarbonate, I. Boustead, APME, 1997, data from Tables 7-13. (APME = Association of Plastics Manufacturers in Europe)
Notes	In the result tables in the ''Eco-profiles...'' report 13, not only total fuels and feedstocks, emissions to air and water, and solid waste are presented, but also the amounts caused by fuel production, fuel use, transport, feedstock (only for fuels and feedstocks) and processes. As the APME substance nomenclature and the ABB database nomenclature sometimes differ, the original APME substance name is given within '''' in the flow metadata Notes field, if the name has been changed significantly. The following emissions ''<1 mg'' to air have been excluded from the data set by the editor: ''N2O'', ''Cl2'', ''Pb'', ''F2'', ''Mercaptans'', H2SO4'', ''Hg''. The following emissions ''<1 mg'' to water have been excluded from the data set by the editor: ''Al3+'', ''Cu+/Cu2+'', ''Hg'', ''K+'', ''Ni2+'', ''Zn2+'', ''NO3-'', ''Dissolved Cl2'', ''Sulphur/Sulphide''. The following solid waste ''<1 mg'' has been excluded from the data set by the editor: ''To recycling''. The following raw materials <0,1 g have been excluded from the data set by the editor: ''Calcium sulphate'', ''Clay'', ''Dolomite'', ''Gravel'', ''Lead'', ''Olivine'', ''Potassium chloride'', ''Shale''. The following gross primary fuel and feedstock ''<0,01 MJ'' has been excluded from the data set by the editor: ''Wood''. 991122 SECRC/GM

Flow Table and Specific Meta Data

About Inventory	
Publication	''Eco-profiles of the European plastics industry'' Report 13: Polycarbonate, I. Boustead, APME, 1997, data from Tables 7-13. Report 2: Olefin feedstock sources, I. Boustead, APME, 1993. Report 3: Polyethylene and polypropylene, I. Boustead, APME, 1993. Report 4: Polystyrene, I. Boustead, APME, 1997 (2nd ed'n). (APME = Association of Plastics Manufacturers in Europe) The APME project co-ordinator: Vince Matthews. The members of the original independent expert panel: Ian Boustead, Paul Fink, Horst Langowski, Gustav Sundstrom. -- Editor: Data entered into the SPINE format by Gunnar Mattsson, ABB Corporate Research, 1999-11-22 Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology, Göteborg
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	1) Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2) Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i e LCAs) of individual products.
Commissioner	- APME, Association of Plastics Manufacturers in Europe Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels .

Applicability	The data are calculated on a cradle to gate basis, therefore, no supplier activities should be connected to, e g, nuclear power, coal and limestone.
About Data	European average data for polycarbonate production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. Data on the polycarbonate production processes have been supplied by the 3 producers in Europe and some suppliers of major raw materials. These companies were requested to supply data for a 12 month period during 1992-94. Data should be fairly representative for production of polycarbonate in Europe. However, the data quality is dependent on the quality of the records maintained by the individual companies. Site-specific data for raw materials and fuels have been used when available. Data from other manufacturers have been used in other cases. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency. No other process data have been derived from the literature. For fuels and energy, the following gross calorific values (energy content) have been used in the calculations: 45,0 MJ/kg for oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal, 15,0 MJ/kg for lignite, 9,3 MJ/kg for sulphur.

Technical System	
Name	Extraction to polyethylene all grades APME
Functional Unit	1 kg of polyethylene all grades
Functional Unit Explanation	Low density polyethylene (LDPE), high density polyethylene (HDPE) and linear low density polyethylene (LLDPE) granules. Data were obtained from a total of 36 European ethylene polymerisation plants producing 4,5E6 tonnes of polyethylene of all grades: 10 plants produced 1,3E6 tonnes of HDPE, 22 plants produced 2,8E6 tonnes of LDPE, and 4 plants produced 0,36E6 tonnes of LLDPE. Although conversion of resin to granules has been included for the granulated products, the data are based on production of all saleable products, including any sub-standard resin that is sold for other uses.
Process Type	Cradle to gate
Site	European average values, Used for identification of owner and/or site in Object of study under Technical system for activity
Sector	Materials and components
Owner	European average values, Used for identification of owner and/or site in Object of study under Technical system for activity
Technical system description	The following major processes are included: North Sea gas extraction and delivery; North Sea crude oil extraction and delivery; crude oil extraction from other sources + average tanker transport of crude oil to Europe; oil refining for naphtha; cracking of naphtha to ethene, propene etc; polymerisation of ethylene to low density polyethylene (LDPE), high density polyethylene (HDPE) or linear low density polyethylene (LLDPE); conversion of resins to granules. Also electricity production, steam production and production of other raw materials have been included on a cradle to gate basis, i e all materials and energies have been traced back to the extraction of raw materials from the earth. Operating conditions: As the data are based on information from a large number of plants in different European countries, the operating conditions differ a lot. Some general information about the chemical processes are found in the ''Eco-profiles...'' reports. The polymerisation process, for instance, are described at p 1 in Report 3. If it was not known whether a plant specifically used North Sea gas or oil, or non-North Sea oil, as the primary feedstock, it was assumed that the mix of North Sea crude oil and non-North Sea crude oil into the refineries was the same as for all EC countries (around 1990), i e 15% derived from North Sea oil and 85% from non-North Sea sources. Only data from two oil wells outside the North Sea area were available. When the ethylene sources for a polymerisation plant were known, site-specific data were used, otherwise average values. Most refineries and many polymerisation plants generate steam on-site and, in many instances, electricity is co-generated. Where plant details were not available, average values were used. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency.

System Boundaries	
Nature Boundary	As the level of detail in data supplied by the producers varied significantly from one producer to another, the level of detail in the final result is governed, to a great extent, by the returned data with the lowest level of detail. For instance, hydrocarbon emissions are presented as Hydrocarbons, although some producers provided data for individual hydrocarbons.
Time Boundary	Data were collected around 1990. The exact year is not stated. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older. For ethylene production, it is thought that the data is ''a good representation of typical averge European practice during the period 1989-90''.
Geographical Boundary	European average. No specific sites are mentioned. Data were obtained from a total of 36 European ethylene polymerisation plants producing 4,5E6 tonnes of polyethylene of all grades: 10 plants produced 1,3E6 tonnes of HDPE, 22 plants produced 2,8E6 tonnes of LDPE, and 4 plants produced 0,36E6 tonnes of LLDPE. For production of major raw materials, data were obtained from 19 crackers, 4 refineries, 3 North Sea oil rig operators, 2 non-North Sea oil wells.
Other Boundaries	Subsystems excluded: - Production of additives such as antioxidants, dyes and fillers. - Outer packaging materials for the final products. - Metallic catalysts used in polymerisation. The system boundaries for extraction of crude oil and gas, oil refining and cracking are not stated in detail, while the system boundaries for electricity production are not stated at all. Hence, it is not known what subsystems have been excluded.

	Hydrocarbon co-monomers added to the polymerisation process have all been treated as hexane. No cut-off criteria for exclusion of minor inputs and outputs are stated.
Allocations	Inputs and outputs to/from the North Sea oil rigs have been partitioned between the different products on the basis of the calorific values of the products. Inputs and outputs to/from the refineries have been partitioned across all usable or saleable refinery products on the basis of mass. This also applies to the products from the crackers.
Systems Expansions	N/A

Flow Data

General Activity QMetaData

Date Conceived	1990
Data Type	Derived, mixed
Represents	As no data for extraction of dolomite in Norway was obtained, figures from Swedish extraction of dolomite has been used.
Method	European average data. Data from 36 ethylene polymerisation plants were averaged over all plants and weighted by the production (mass) from each plant [2]. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers, otherwise horizontal averaging has been applied. In vertical averaging, each production line (i e each polymerisation plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production lines weighted by the output from each production line (polymerisation plant) [3]. For some sub-processes, plant specific data were not available, and average data for that sub-process were used instead (i e horizontal averaging). In the present data set, the proportions of oil and gas, respectively, used as fuel and feedstock, have been corrected according to instructions in ref. [3]. The reason for the correction is that a proportion of the feedstock (gas and oil) inputs to the processes invariably ends up as waste, and that these residues are generally used as fuels within the plants. As a consequence, the amount of CO2 emission to air has also been corrected, since CO2, unlike other emissions, is not measured but calculated from the amounts of combusted fuels. For fuels and energy, the following gross calorific values (energy content) have been used in the calculations: 45,0 MJ/kg for oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal. The following assumed contents of carbon in the fuels have been used in the calculations: 80% in coal, 85,71% in oil, 75,0% in gas. 1 kg carbon in a fuel gives rise to 3,67 kg of CO2.
Literature Reference	''Eco-profiles of the European plastics industry'' [1] Report 2: Olefin feedstock sources, I. Boustead, APME/PWMI, 1993. [2] Report 3: Polyethylene and polypropylene, I. Boustead, APME/PWMI, 1993, data from Tables 12-14. [3] Report 4: Polystyrene (2nd ed'n), I. Boustead, APME, 1997, p 13-14, 33. (APME = Association of Plastics Manufacturers in Europe, PWMI = European Centre for Plastics in the Environment)
Notes	As the APME substance nomenclature and the ABB database nomenclature sometimes differ, the original APME substance name is given within '''' in the flow metadata Notes field, if the name has been changed significantly. The following feedstock materials ''<0.01 MJ'' have been excluded from the data set by the editor: ''Coal'', ''Wood''. The following raw material ''<1 mg'' has been excluded from the data set by the editor: ''Ferromanganese''. 991122 SECRC/GM

Applicability	The present data for polyethylene all grades could be used whenever the exact type of PE is not known. For LDPE, HDPE and LLDPE, there are specific data from APME in separate data sets. The data are calculated on a cradle to gate basis, therefore, no supplier activities should be connected to, e g, nuclear power, coal and limestone.
About Data	European average data for polyethylene production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with four independent experts on LCA (eco-balance analysis). The independent panel of experts supervised the study and developed the methodology for collecting, analysing and presenting the inventory data. The initial set of data was collected by sending out a standard questionnaire to the producers. Data on the polyethylene production processes have been supplied by the 36 producers in Europe. Data are average values weighted by the mass of polyethylene produced by each of the polymerisation plants. As a large number of producers have participated in the study, the data should be fairly representative for production of polyethylene in Europe. Site-specific data for raw materials and fuels have been used when available. Average values have been used in other cases. However, it should be borne in mind that data for some supplying processes are based on only a few plants. For instance, only data from two non-North Sea oil wells were available. The source and quality of data for public electricity production are not stated. The range of total gross energy (fuels + feedstock) consumed was 69-107 MJ/kg with a weighted average of 85,83 MJ. The range is not a statistical variation, but reflects different technologies, feedstocks, transports and operating conditions in different countries and plants. For fuels and energy, the following gross calorific values (energy content) have been used in the calculations: 45,0 MJ/kg for oil, 38,8 MJ/m3 (54,1 MJ/kg) for natural gas, 28,0 MJ/kg for coal. The accuracy of the data for air and water emissions varies for the different emissions. In general, more accurate information are available on those emissions statutorily regarded as having a more severe effect on the environment. This is because they are more closely measured in order to satisfy the local pollution regulations. Conversely, many of the non-regulated emissions are usually estimates. A large number of emissions have been aggregated into general groups, e g Metals, Hydrocarbons, Dissolved organics. The CO2 emissions to air have been calculated from the consumption of fossil fuels in the different processes. Since feedstock waste materials arising during production are used as fuels in the processes, the amounts of supplied feedstock inputs (oil and gas) should be adjusted for these residues. In the present data set, the feedstock inputs have indeed been reduced, and the fuel inputs and CO2 emissions have been increased correspondingly, in order to account for the amounts of feedstock estimated to be used as fuel.
Notes	

SPINE LCI dataset: Extraction to polyethylene HD APME

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Extraction to polyethylene HD APME
Functional Unit	1 kg of high density polyethylene (HDPE)

Functional Unit Explanation	HDPE resin, which is, for example, used in the production of HDPE food containers, automobile fuel tanks, bottles, pipes and film. It is not explained in the Eco-profiles report what is meant by ''resin'', but a fair guess is that the physical form of the polymer product is granules, as this is the most important product delivered by the polymerisation plants to their customers.
Process Type	Cradle to gate
Site	European average Used for identification of owner and/or site in Object of study under Technical system for activity
Sector	Materials and components
Owner	European average Used for identification of owner and/or site in Object of study under Technical system for activity
Technical system description	Production of high density polyethylene (HDPE) including all major operations from extraction of crude oil and gas to polymerisation. HDPE is produced in a low pressure process and contains fewer side branches than low density polyethylene, which accounts for a more regular structure and a higher density. Polyethylene is usually polymerised by a free radical mechanism in which an initiator opens the double bond of the ethene (CH2=CH2) molecule and attaches itself, leaving the other ''open'' bond, or radical, free to attack a further ethene molecule. The process repeats itself until all of the monomer is used up or, more commonly, the reactive end is itself terminated by specifically added reactants. Cracking of naphtha to ethene, propene etc: The output fractions from an oil refinery are complex mixtures of mostly unreactive saturated hydrocarbons. Cracking is performed to 1) reduce the variety and size of the hydrocarbons, 2) introduce unsaturation into the hydrocarbons. In addition to the mentioned processes, the following major processes are included: Crude oil extraction and delivery; oil refining for naphtha (fractional distillation); natural gas extraction, processing and delivery; coal mining and delivery. Also electricity production and production of other raw materials have been included on a cradle to gate basis, i.e. all materials and energies have been traced back to the extraction of raw materials from the earth. Operating conditions: As the data are based on information from 10 plants in 7 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. Some more information about the processes are found in the ''Eco-profiles...'' reports for high density polyethylene (LDPE), ethylene and naphtha, and in the Methodology report, which are available at APME''s web site http://lca.apme.org.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available.'' Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under their specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment. Emissions <0.5 mg were presented as <1 mg in the Eco-profiles result tables. In this activity, however, they are presented as 0.25 mg (1/2 of the maximum value 0.5 mg). Note that the actual values may be far below 0.5 mg in some cases. The energy resources Hydrogen and Sulphur have been excluded by GM, since these parameters do not represent true natural resources, but are reported as primary energy equivalents for energy balancing purposes. Probably they are included in other resources, e.g. crude oil and gas. Nuclear energy has been recalculated to natural uranium resource. Only Hydro energy and Unspecified energy are kept as primary energy equivalents in the flow table.
Time Boundary	Data refer to the years 1992-93. Data for upstream production of crude oil, naphtha and ethylene are from 1990-96; data for production of other fuels and raw materials are probably from the same time, or somewhat older.

Geographical Boundary	European average data. Results are based on data for 10 polyethylene HD production plants that produced 1.32 million tonnes (32% of the total European production in 1997). Data were supplied by 10 plants in 7 countries: Austria, Belgium, France, Netherlands, Portugal, Sweden, UK. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates. For the intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides that plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included.) - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most other cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0.01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Methodology report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g., sulphuric acid is used as a drying agent for chlorine; therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity.
Systems Expansions	Not applied. The amount of Recovered energy is reported as a negative primary energy equivalent input.

Flow Data

General Activity QMetaData

Date Conceived	1992 to 1993
Data Type	Derived, mixed
Represents	As no data for extraction of dolomite in Norway was obtained, figures from Swedish extraction of dolomite has been used.
Method	European average data. Results are based on data supplied by 10 production plants in 7 countries: Austria, Belgium, France, Netherlands, Portugal, Sweden, UK. Their total production was 1.32 million tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations.

	According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45.0 MJ/kg for crude oil, 38.8 MJ/m3 (54.1 MJ/kg) for natural gas, 28.0 MJ/kg for coal, 15.0 MJ/kg for lignite, 9.3 MJ/kg for sulphur. Emissions and resources <0.5 mg have been assumed by Gunnar Mattson, ABB Corporate Research (GM) to be 0.25 mg, i.e. half the ''<'' values given, which is in accordance with common statistical procedure. The energy resources Hydrogen (0.15 MJ) and Sulphur (<0.01 MJ) have been excluded by GM, since these parameters do not represent true natural resources, but are reported as primary energy equivalents for energy balancing purposes. Probably they are included in other resources, e.g. crude oil and gas. Nuclear energy has been recalculated to natural uranium resource. Only Hydro energy and Unspecified energy are kept as primary energy equivalents in the flow table. 2001-05-30 SECRC/GM
Literature Reference	''Eco-profiles of the European plastics industry'', reports for high density polyethylene (HDPE), ethylene and naphtha. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. (APME = Association of Plastics Manufacturers in Europe)
Notes	In the result tables in the ''Eco-profiles...'' report, not only total fuels and feedstocks, emissions to air and water, and solid waste are presented, but also the amounts caused by fuel production, fuel use, transport, feedstock (only for fuels and feedstocks) and processes. As the APME substance nomenclature and the ABB database nomenclature sometimes differ, the original APME substance name is given within '''' in the flow metadata Notes field. Please note: Some other interpretations/changes have been made from the original report by Gunnar Mattson, ABB Corporate Research. See Method and AboutData for details.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', reports for high density polyethylene (HDPE), ethylene and naphtha. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. (APME = Association of Plastics Manufacturers in Europe) The APME project co-ordinator: Vince Matthews. The members of the original independent expert panel: Ian Boustead, Paul Fink, Horst Langowski, Gustav Sundstrom. -- Editor: Data were entered into the SPINE format by Gunnar Mattsson, ABB Corporate Research, 2001-05-30. Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 29 October 2001 --
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as building blocks for use in the construction of complete life cycle analyses. 1) Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2) Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of

	individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies. - Internal company benchmarking. - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occurred since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	- APME, Association of Plastics Manufacturers in Europe Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels .
Practitioner	Boustead, Ian - .
Reviewer	
Applicability	The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for high density polyethylene production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data on the HDPE production processes have been supplied by 10 plants in 7 European countries. Data are probably fairly representative for production of HDPE in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Note that emissions <0.5 mg (0.25 mg in data table) may be far below 0.5 mg in some cases. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, data for each production sequence (i.e. each plant + its specific suppliers) are calculated separately. The final result is the average of the results from the individual production sequences weighted by the output from each sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45.0 MJ/kg for crude oil, 38.8 MJ/m3 (54.1 MJ/kg) for natural gas, 28.0 MJ/kg for coal, 15.0 MJ/kg for lignite, 9.3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission (kg/MJ fuel) = 3.67 x {mass fraction of carbon in fuel}/{calorific value of fuel}. The following interpretations/changes have been made by Gunnar Mattson, ABB Corporate Research: - Nuclear energy has been recalculated to natural uranium resource. - Ferromanganese, Phosphate and Rutile have been recalculated to the corresponding amounts of Mn, P and Ti resources.

	- The energy resources Hydrogen and Sulphur have been excluded, as these parameters do not represent true natural resources. - Emissions and resources <0.5 mg (<1 mg in the Eco-profiles result tables) are presented as 0.25 mg, i.e. 1/2 of the ''<'' value. This is in accordance with common statistical procedure.

SPINE LCI dataset: Extraction to polyethylene LD APME

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Extraction to polyethylene LD APME
Functional Unit	1 kg of low density polyethylene (LDPE)
Functional Unit Explanation	LDPE resin, which is typically used in the production of LDPE film and containers. It is not explained in the Eco-profiles report what is meant by ''resin'', but a fair guess is that the physical form of the polymer product is granules, as this is the most important product delivered by the polymerisation plants to their customers.
Process Type	Cradle to gate
Site	European average Used for identification of owner and/or site in Object of study under Technical system for activity
Sector	Materials and components
Owner	European average Used for identification of owner and/or site in Object of study under Technical system for activity
Technical system description	Production of low density polyethylene (LDPE) including all major operations from extraction of crude oil and gas to polymerisation. LDPE is produced in a high pressure process and contains a high level of side branching with relatively long side chains, which accounts for LDPE''s relatively low density. Polyethylene is usually polymerised by a free radical mechanism in which an initiator opens the double bond of the ethene (CH2=CH2) molecule and attaches itself, leaving the other ''open'' bond, or radical, free to attack a further ethene molecule. The process repeats itself until all of the monomer is used up or, more commonly, the reactive end is itself terminated by specifically added reactants. Cracking of naphtha to ethene, propene etc: The output fractions from an oil refinery are complex mixtures of mostly unreactive saturated hydrocarbons. Cracking is performed to 1) reduce the variety and size of the hydrocarbons, 2) introduce unsaturation into the hydrocarbons. In addition to the mentioned processes, the following major processes are included: Crude oil extraction and delivery; oil refining for naphtha (fractional distillation); natural gas extraction, processing and delivery; coal mining and delivery. Also electricity production and production of other raw materials have been included on a cradle to gate basis, i.e. all materials and energies have been traced back to the extraction of raw materials from the earth. Operating conditions: As the data are based on information from 15 plants in 7 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. Some more information about the processes are found in the ''Eco-profiles...'' reports for low density polyethylene (LDPE), ethylene and naphtha, and in the Methodology report, which are available at APME''s web site http://lca.apme.org.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available.'' Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under their specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment. Emissions <0.5 mg were presented as <1 mg in the Eco-profiles result tables. In this activity, however, they are presented as 0.25 mg (1/2 of the maximum value 0.5 mg). Note that the actual values may be far below 0.5 mg in some cases. The energy resources Hydrogen and Sulphur have been excluded by GM, since these parameters do not represent true natural resources, but are reported as primary energy equivalents for energy balancing purposes. Probably they are included in other resources, e.g. crude oil and gas. Nuclear energy has been recalculated to natural uranium resource. Only Hydro energy and Unspecified energy are kept as primary energy equivalents in the flow table.
Time Boundary	Data refer to the years 1989-92. Data for upstream production of crude oil, naphtha and ethylene are from 1990-96; data for production of other fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Results are based on data for 15 polyethylene LD production plants that produced 2.3 million tonnes (47% of the total European production in 1997). Data were supplied by 15 plants in 7 countries: Austria, Belgium, Finland, Netherlands, Portugal, Sweden, UK. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates. For the intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides that plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included.) - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most other cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0.01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Methodology report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g., sulphuric acid is used as a drying agent for chlorine; therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or

	chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity.
Systems Expansions	Not applied. The amount of Recovered energy is reported as a negative primary energy equivalent input.

Flow Data

General Activity QMetaData

Date Conceived	1989 to 1992
Data Type	Derived, mixed
Represents	As no data for extraction of dolomite in Norway was obtained, figures from Swedish extraction of dolomite has been used.
Method	European average data. Results are based on data supplied by 15 production plants in 7 countries: Austria, Belgium, Finland, Netherlands, Portugal, Sweden, UK. Their total production was 2.3 million tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45.0 MJ/kg for crude oil, 38.8 MJ/m3 (54.1 MJ/kg) for natural gas, 28.0 MJ/kg for coal, 15.0 MJ/kg for lignite, 9.3 MJ/kg for sulphur. Emissions and resources <0.5 mg have been assumed by Gunnar Mattson, ABB Corporate Research (GM) to be 0.25 mg, i.e. half the ''<'' values given, which is in accordance with common statistical procedure. The energy resources Hydrogen (0.11 MJ) and Sulphur (<0.01 MJ) have been excluded by GM, since these parameters do not represent true natural resources, but are reported as primary energy equivalents for energy balancing purposes. Probably they are included in other resources, e.g. crude oil and gas. Nuclear energy has been recalculated to natural uranium resource. Only Hydro energy and Unspecified energy are kept as primary energy equivalents in the flow table. 2001-05-29 SECRC/GM
Literature Reference	''Eco-profiles of the European plastics industry'', reports for low density polyethylene (LDPE), ethylene and naphtha. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. (APME = Association of Plastics Manufacturers in Europe)
Notes	In the result tables in the ''Eco-profiles...'' report, not only total fuels and feedstocks, emissions to air and water, and solid waste are presented, but also the amounts caused by fuel production, fuel use, transport, feedstock (only for fuels and feedstocks) and processes. As the APME substance nomenclature and the ABB database nomenclature sometimes differ, the original APME substance name is given within '''' in the flow metadata Notes field. Please note: Some other interpretations/changes have been made from the original report by Gunnar Mattson, ABB Corporate Research. See Method and AboutData for details.

About Inventory

Publication	''Eco-profiles of the European plastics industry'', reports for low density polyethylene (LDPE), ethylene and naphtha. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org.

	(APME = Association of Plastics Manufacturers in Europe) The APME project co-ordinator: Vince Matthews. The members of the original independent expert panel: Ian Boustead, Paul Fink, Horst Langowski, Gustav Sundstrom. -- Editor: Data were entered into the SPINE format by Gunnar Mattsson, ABB Corporate Research, 2001-05-29. Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 29 October 2001 --
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as building blocks for use in the construction of complete life cycle analyses. 1) Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2) Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies. - Internal company benchmarking. - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occurred since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	- APME, Association of Plastics Manufacturers in Europe Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels .
Practitioner	Boustead, Ian - .
Reviewer	
Applicability	The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows. Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for low density polyethylene production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data on the LDPE production processes have been supplied by 15 plants in 7 European countries. Data are probably fairly representative for production of LDPE in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Note that emissions <0.5 mg (0.25 mg in data table) may be far below 0.5 mg in some cases.

	Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, data for each production sequence (i.e. each plant + its specific suppliers) are calculated separately. The final result is the average of the results from the individual production sequences weighted by the output from each sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45.0 MJ/kg for crude oil, 38.8 MJ/m3 (54.1 MJ/kg) for natural gas, 28.0 MJ/kg for coal, 15.0 MJ/kg for lignite, 9.3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission (kg/MJ fuel) = 3.67 x {mass fraction of carbon in fuel}/{calorific value of fuel}. The following interpretations/changes from the original report have been made by Gunnar Mattson, ABB Corporate Research: - Nuclear energy has been recalculated to natural uranium resource. - Ferromanganese, Phosphate and Rutile have been recalculated to the corresponding amounts of Mn, P and Ti resources. - The energy resources Hydrogen and Sulphur have been excluded, as these parameters do not represent true natural resources. - Emissions and resources <0.5 mg (<1 mg in the Eco-profiles result tables) are presented as 0.25 mg, i.e. 1/2 of the ''<'' value. This is in accordance with common statistical procedure.
Notes	

SPINE LCI dataset: Extraction to polyethylene linear LD APME

Administrative	
Finished	Y
Date Completed	1999
Copyright	APME
Availability	Public

Technical System	
Name	Extraction to polyethylene linear LD APME
Functional Unit	1 kg of linear low density polyethylene (LLDPE)
Functional Unit Explanation	LLDPE resin. It is not explained in the Eco-profiles report what is meant by ''resin'', but a fair guess is that the physical form of the polymer product is granules, as this is the most important product delivered by the polymerisation plants to their customers.
Process Type	Cradle to gate
Site	European average Used for identification of owner and/or site in Object of study under Technical system for activity
Sector	Materials and components
Owner	European average Used for identification of owner and/or site in Object of study under Technical system for activity
Technical system description	Production of linear low density polyethylene (LLDPE) including all major operations from extraction of crude oil and gas to polymerisation. LLDPE contains a large number of side branches but they are very short so that the polymer is able to pack well in the solid state. Polyethylene is usually polymerised by a free radical mechanism in which an initiator opens the double bond of the ethene (CH2=CH2) molecule and attaches itself, leaving the other ''open'' bond, or radical, free to attack a further ethene molecule. The process repeats itself until all of the monomer is used up or, more commonly,

	the reactive end is itself terminated by specifically added reactants. Cracking of naphtha to ethene, propene etc: The output fractions from an oil refinery are complex mixtures of mostly unreactive saturated hydrocarbons. Cracking is performed to 1) reduce the variety and size of the hydrocarbons, 2) introduce unsaturation into the hydrocarbons. In addition to the mentioned processes, the following major processes are included: Crude oil extraction and delivery; oil refining for naphtha (fractional distillation); natural gas extraction, processing and delivery; coal mining and delivery. Also electricity production and production of other raw materials have been included on a cradle to gate basis, i.e. all materials and energies have been traced back to the extraction of raw materials from the earth. Operating conditions: As the data are based on information from 3 plants in 2 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. Some more information about the processes are found in the ''Eco-profiles...'' reports for linear low density polyethylene (LLDPE), ethylene and naphtha, and in the Methodology report, which are available at APME''s web site http://lca.apme.org.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available.'' Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under their specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment. Emissions <0.5 mg were presented as <1 mg in the Eco-profiles result tables. In this activity, however, they are presented as 0.25 mg (1/2 of the maximum value 0.5 mg). Note that the actual values may be far below 0.5 mg in some cases. The energy resources Hydrogen and Sulphur have been excluded by GM, since these parameters do not represent true natural resources, but are reported as primary energy equivalents for energy balancing purposes. Probably they are included in other resources, e.g. crude oil and gas. Nuclear energy has been recalculated to natural uranium resource. Only Hydro energy and Unspecified energy are kept as primary energy equivalents in the flow table.
Time Boundary	Data refer to the years 1990-92. Data for upstream production of crude oil, naphtha and ethylene are from 1990-96; data for production of other fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Results are based on data for 3 polyethylene linear LD production plants that produced 341000 tonnes (21% of the total European production in 1997). Data were supplied by 3 plants in 2 countries: France, Netherlands. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates. For the intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides that plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included.) - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most other cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0.01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Methodology report, a general recommendation is given that it is important to demonstrate

	that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g., sulphuric acid is used as a drying agent for chlorine; therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity.
Systems Expansions	Not applied. The amount of Recovered energy is reported as a negative primary energy equivalent input.

Flow Data

General Activity QMetaData

Date Conceived	1990 to 1992
Data Type	Derived, mixed
Represents	As no data for extraction of dolomite in Norway was obtained, figures from Swedish extraction of dolomite has been used.
Method	European average data. Results are based on data supplied by 3 production plants in 2 countries: France, Netherlands. Their total production was 341000 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45.0 MJ/kg for crude oil, 38.8 MJ/m3 (54.1 MJ/kg) for natural gas, 28.0 MJ/kg for coal, 15.0 MJ/kg for lignite, 9.3 MJ/kg for sulphur. Emissions and resources <0.5 mg have been assumed by GM to be 0.25 mg, i.e. half the ''<'' values given, which is in accordance with common statistical procedure. The energy resources Hydrogen (0.02 MJ) and Sulphur (<0.01 MJ) have been excluded by GM, since these parameters do not represent true natural resources, but are reported as primary energy equivalents for energy balancing purposes. Probably they are included in other resources, e.g. crude oil and gas. Nuclear energy has been recalculated to natural uranium resource. Only Hydro energy and Unspecified energy are kept as primary energy equivalents in the flow table. 2001-05-30 SECRC/GM
Literature Reference	''Eco-profiles of the European plastics industry'', reports for linear low density polyethylene (LLDPE), ethylene and naphtha. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. (APME = Association of Plastics Manufacturers in Europe)
Notes	In the result tables in the ''Eco-profiles...'' report, not only total fuels and feedstocks, emissions to air and water, and solid waste are presented, but also the amounts caused by fuel production, fuel use, transport, feedstock (only for fuels and feedstocks) and processes. As the APME substance nomenclature and the ABB database nomenclature sometimes differ, the original APME substance name is given within '''' in the flow metadata Notes field. Please note: Some other interpretations/changes have been made from the original report by Gunnar Mattson, ABB Corporate Research. See Method and AboutData for details.

About Inventory	
Publication	''Eco-profiles of the European plastics industry'', reports for linear low density polyethylene (LLDPE), ethylene and naphtha. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. (APME = Association of Plastics Manufacturers in Europe) The APME project co-ordinator: Vince Matthews. The members of the original independent expert panel: Ian Boustead, Paul Fink, Horst Langowski, Gustav Sundstrom. -- Editor: Data were entered into the SPINE format by Gunnar Mattsson, ABB Corporate Research, 2001-05-30. Documentation reviewed by: Ann-Christin Pålsson, CPM, Chalmers University of Technology Published in SPINE@CPM: 29 October 2001 --
Intended User	1. APME member companies 2. L
General Purpose	The general purpose of the study was to demonstrate the commitment of APME (Association of Plastics Manufacturers in Europe) to improve the environmental impact of the processes, from extraction of oil to granulate or polymer compound.
Detailed Purpose	Eco-profiles are intended primarily as building blocks for use in the construction of complete life cycle analyses. 1) Provide APME member companies with information which will highlight potential areas for improving manufacturing processes, 2) Provide valuable inventory data for downstream users of plastics, such as packaging manufacturers, who will be able to produce their own eco-balance assessments (i.e. LCAs) of individual products. Objectives and areas of application for the Eco-profiles: - Plastics waste management studies. - Internal company benchmarking. - Product development. Detailed environmental information to customers of APME members for use in improving the overall environmental performance of products and systems. - Ensuring that the data are neutral. The purpose of the 1999 update was to re-issue all of the data sets together using the latest data available and with all of the results forming a consistent data set. Significant technological and commercial changes have occurred since 1989-93, the period to which the oldest group of Eco-profile data referred. Also the quality of data reported by the companies has improved since then.
Commissioner	- APME, Association of Plastics Manufacturers in Europe Avenue E. van Nieuwenhuyse 4 Box 3 B-1160 Brussels .
Practitioner	Boustead, Ian - .

Applicability	The data are calculated on a cradle to gate basis, therefore, nuclear power, coal, limestone etc should be regarded as resources from environment, i.e. no supplier activities should be connected to these flows.

	Remember that, in an LCA, two systems could only be compared if they perform equivalent functions. For instance, production of 1 kg of polyethylene should not be compared directly with production of 1 kg of polycarbonate. Only in a specific application, a comparison between the two materials could be meaningful. It is not reported how large differences there are between different producers with respect to emissions and other environmental impacts. Therefore, it is also not known how well the data could represent production at a specific plant.
About Data	European average data for linear low density polyethylene production on a cradle to gate basis, issued by APME (Association of Plastics Manufacturers in Europe), and produced in association with the independent expert I. Boustead. The companies participating in the project have supplied data on the chemical processes. Data on the LLDPE production processes have been supplied by 3 plants in 2 European countries. It is not known how representative data are for production of LLDPE in Europe. However, the reliability of the data depends on the quality of the records maintained by the individual companies. Mass and energy balances have been checked, and the details of all calculations were referred back to individual companies for checking before being incorporated into the final averages. Data for supporting operations and transport have been obtained from other manufacturers and operators as part of an on-going exercise involved in maintaining an LCI database. The quality of data for public electricity production is not described. However, it is stated that information on the production of fuels and energy have been derived from the reports of the International Energy Agency 1996, which contain data for 1995. No other process data have been derived from the literature. The accuracy of data for materials and energy supplied by companies is considered to be about 5-10%. Wastes and emissions are often measured with less accuracy. Even for a regulated emission, the procedure for measuring and reporting is usually based on sampling rather than continuous monotoring. The accuracy is often unknown. Note that emissions <0.5 mg (0.25 mg in data table) may be far below 0.5 mg in some cases. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, data for each production sequence (i.e. each plant + its specific suppliers) are calculated separately. The final result is the average of the results from the individual production sequences weighted by the output from each sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45.0 MJ/kg for crude oil, 38.8 MJ/m3 (54.1 MJ/kg) for natural gas, 28.0 MJ/kg for coal, 15.0 MJ/kg for lignite, 9.3 MJ/kg for sulphur. The following degrees of efficiencies have been used to convert electricity production in nuclear plants and hydro plants, respectively, to primary energy equivalents: 35% for nuclear electricity, 80% for hydro electricity. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. CO2 emission values have been calculated from the composition of the fuel, assuming complete combustion: CO2 emission (kg/MJ fuel) = 3.67 x {mass fraction of carbon in fuel}/{calorific value of fuel}. The following interpretations/changes from the original report have been made by Gunnar Mattson, ABB Corporate Research: - Nuclear energy has been recalculated to natural uranium resource. - Ferromanganese, Phosphate and Rutile have been recalculated to the corresponding amounts of Mn, P and Ti resources. - The energy resources Hydrogen and Sulphur have been excluded, as these parameters do not represent true natural resources. - Emissions and resources <0.5 mg (<1 mg in the Eco-profiles result tables) are presented as 0.25 mg, i.e. 1/2 of the ''<'' value. This is in accordance with common statistical procedure.

Technical System

Name	Extraction to SAN APME
Functional Unit	1 kg of SAN (styrene-acrylonitrile copolymer)
Functional Unit Explanation	SAN is a copolymer of styrene (C6H5-CH=CH2) and acrylonitrile (CH2=CH-CN. Typical uses of SAN: kitchen appliances, refrigerator inner parts, food containers, lighting and glazing parts, blend polymer with polybutadiene in ABS.
Process Type	Cradle to gate
Site	European average Used for identification of owner and/or site in Object of study under Technical system for activity
Sector	Materials and components
Owner	European average Used for identification of owner and/or site in Object of study under Technical system for activity
Technical system description	Production of SAN (styrene-acrylonitrile copolymer) including all major operations from extraction of crude oil and gas to polymerisation. SAN is produced in the same production sequence as ABS (acrylonitrile-butadiene-styrene copolymer), which means that the technical system is similar. According to a schematic flow diagram in the ''Eco-profiles...'' report, the following sub-processes are included: - Cracking of naphtha and/or natural gas for ethylene, propylene and butenes. - Styrene production: Reforming of naphtha for benzene + production of benzene from cracking products (''pygas'') in an aromatics plant, ethylene from cracker, ethylbenzene production, styrene production. - Acrylonitrile production: Propylene from cracker, production of ammonia from natural gas and air, production of acrylonitrile from ammonia and propylene. - SAN production from styrene and acrylonitrile. In addition to the mentioned sub-processes, the following major processes are included: Crude oil extraction and delivery; oil refining for naphtha (fractional distillation); natural gas extraction, processing and delivery; coal mining and delivery. Also electricity production and production of other raw materials have been included on a cradle to gate basis, i.e. all materials and energies have been traced back to the extraction of raw materials from the earth. Operating conditions: As the data are based on information from 3 plants in 2 different European countries, the operating conditions differ. For the electricity taken in from the public supply, the calculations have taken account of the country specific electricity production efficiency. Some more information about the processes are found in the ''Eco-profiles...'' reports for SAN (styrene-acrylonitrile copolymer), naphtha and the other intermediates, and the Methodology report, which are available at APME''s web site http://lca.apme.org.

System Boundaries

Nature Boundary	''The data presented in the result tables are simply a listing of the data for which information is available.'' Especially for air and water emissions, the magnitude of many of the parameters often depends on the degree of monitoring of the parameter, since a company which does not monitor the parameter, may have estimated it instead. The categories used to identify the different emissions or groups of emissions are empirical and reflect the ability of the many plants to identify specific emissions. For instance, methane, aromatic hydrocarbons and polycyclic hydrocarbons have been identified as separate groups, while the more general name hydrocarbons has been reserved for the remainder. However, some companies may not have reported all of the emissions separately. Therefore, the category metals, for example, may include some metals which were specifically identified by other companies and are included under their specific names elsewhere in the tables. Double-counting has been avoided. However, some of the emissions included separately may have contributed to the BOD and COD values. Generally, the emissions to air and water recorded are those remaining after any on-site air or water treatment. Emissions <0.5 mg were presented as <1 mg in the Eco-profiles result tables. In this activity, however, they are presented as 0.25 mg (1/2 of the maximum value 0.5 mg). Note that the actual values may be far below 0.5 mg in some cases. The energy resources Hydrogen and Sulphur have been excluded by GM, since these parameters do not represent true natural resources, but are reported as primary energy

	equivalents for energy balancing purposes. Probably they are included in other resources, e.g. crude oil and gas. Nuclear energy has been recalculated to natural uranium resource. Only Hydro energy and Unspecified energy are kept as primary energy equivalents in the flow table.
Time Boundary	Data refer to the years 1994 to 1995. Data for upstream production of fuels and raw materials are probably from the same time, or somewhat older.
Geographical Boundary	European average data. Results are based on data for 3 SAN production plants that produced 115 000 tonnes (unknown fraction of the total European production). Data were supplied by 3 plants in 2 countries: Germany and Netherlands. For the APME Eco-profiles in general, the coverage of European production varies from 60 to 100% depending upon the product, although this may not be true for some of the intermediates. For the intermediates, with the exception of chlorine, sodium hydroxide and electrolytic hydrogen, the average data might not be truly representative of the European average for their production. The values of some of the parameters reflect the country in which the plants are located. For example, plants in countries where much of the electricity is generated from coal, tend to exhibit higher emissions of sulphur oxides that plants in other countries.
Other Boundaries	The following excluded subsystems are explicitly mentioned in the Methodology report: - External incineration of waste and external recycling. Other external waste treatment is, most likely, also excluded, as concluded by the way solid waste is classified. (On-site waste incineration, on the other hand, is included.) - Energy consumption and emissions caused by operating personnel: consumption of food and car transports to work. Both were considered to be small compared to the totals. - Capital equipment and buildings, with two exceptions: road transport and oil well operation. In these two cases, construction and maintenance have been included. In most other cases, the lifetime of the plants is sufficiently long to allow exclusion of capital equipment and buildings, which typically contribute <0.01% to the totals. No cut-off criteria for exclusion of minor inputs and outputs are stated. However, in the Methodology report, a general recommendation is given that it is important to demonstrate that the contribution of an ancillary material to the overall system is negligible, rather than simply assuming it to be negligible because of its small mass.
Allocations	In the Methodology report and the different ''Eco-profiles...'' reports, the following co-product allocations are mentioned: - Extraction of crude oil and natural gas: For the North Sea oil rigs, the flare losses and the own-use data have been spread over all of the saleable products on the basis of their calorific values. - Refineries: Inputs and outputs have been partitioned over all usable or saleable refinery products on a simple mass basis. - Crackers: Most likely, this also applies to the products from the crackers: ethylene, propylene, butenes etc. - Chlorine plant (electrolysis of sodium chloride): Stoichiometric allocation of sodium chloride and some other inputs and outputs has been applied to the three products: chlorine, sodium hydroxide and hydrogen. Care was taken to attribute inputs or outputs only to the products which derive benefit from these inputs or outputs. E.g., sulphuric acid is used as a drying agent for chlorine; therefore, the sulphuric acid input should be attributed to chlorine only. Electricity was partitioned on all products on a simple mass basis. - Sulphuric acid: 98% sulphuric acid is widely used as a drying agent. Often, the dilute acid leaving the system can be used as a reagent in other reactions. However, the dilute acid cannot simply be subtracted from the input acid. The energy needed to produce concentrated acid by removing water is attributed to the process. - Hydrochloric acid by-product: In many reactions, chlorine is used as an oxidation or chlorination agent, which inevitably results in the formation of HCl as a by-product. Only the inputs and outputs associated with the production of the stoichiometric amounts of chlorine and hydrogen incorporated into the HCl have been assigned to the HCl. - On-site steam and electricity: A primary energy equivalent corresponding to the steam energy, assuming 80% efficiency, was subtracted from the total energy input. The remainder was assigned to the electricity.
Systems Expansions	Not applied. The amount of Recovered energy is reported as a negative primary energy equivalent input.

Flow Data

General Activity QMetaData

Date Conceived	1994 to 1995
Data Type	Derived, mixed
Represents	As no data for extraction of dolomite in Norway was obtained, figures from Swedish extraction of dolomite has been used.
Method	European average data. Results are based on data supplied by 3 production plants in 2 countries: Germany and Netherlands. Their total production was 115 000 tonnes. Data were averaged over all plants and weighted by the production (mass) from each plant. Vertical averaging has been applied wherever there have been sufficient data from upstream raw material and fuel producers. In vertical averaging, each production sequence (i.e. each

	plant + its specific suppliers) is calculated separately, and the final result is the average of the results from the individual production sequences weighted by the output from each production sequence (plant). Horizontal averaging has, however, been applied for some processes over which the producers have no control and data from a specific supplier were not available. In these cases, European average data from the other participants or suppliers were used in the calculations. According to the APME methodology report, the amounts of combusted fuels have been corrected by adding the feedstock (gas and oil) residues used as fuel within the processes, before calculating the CO2 emission. For fuels and feedstock materials, actual gross calorific values (energy content) have been used in the calculations. Typical values: 45.0 MJ/kg for crude oil, 38.8 MJ/m3 (54.1 MJ/kg) for natural gas, 28.0 MJ/kg for coal, 15.0 MJ/kg for lignite, 9.3 MJ/kg for sulphur. Emissions and resources <0.5 mg have been assumed by Gunnar Mattson, ABB Corporate research (GM) to be 0.25 mg, i.e. half the ''<'' values given, which is in accordance with common statistical procedure. The energy resources Hydrogen (0.11 MJ) and Sulphur (0.02 MJ) have been excluded by GM, since these parameters do not represent true natural resources, but are reported as primary energy equivalents for energy balancing purposes. Probably they are included in other resources, e.g. crude oil and gas. Nuclear energy has been recalculated to natural uranium resource. Only Hydro energy and Unspecified energy are kept as primary energy equivalents in the flow table. 2001-06-18 SECRC/GM
Literature Reference	''Eco-profiles of the European plastics industry'', report for SAN (styrene-acrylonitrile copolymer), naphtha and the other intermediates. ''Eco-profiles of plastics and related intermediates: Methodology'', I. Boustead, The European Centre for Plastics in the Environment of The Association of Plastics Manufacturers in Europe (APME), Brussels, 1999. Reports are available at APME's web site http://lca.apme.org. (APME = Association of Plastics Manufacturers in Europe)
Notes	In the result tables in the ''Eco-profiles...'' report, not only total fuels and feedstocks, emissions to air and water, and solid waste are presented, but also the amounts caused by fuel production, fuel use, transport, feedstock (only for fuels and feedstocks) and processes. As the APME substance nomenclature and the ABB database nomenclature sometimes differ, the original APME substance name is given within '''' in the flow metadata Notes field. Please note: Some other interpretations/changes have been made from the original report by Gunnar Mattson, ABB Corporate Research. See Method and AboutData for details.
